There is another cause existing to occasion the deviation which is observable in the practical results of the lee-way of a ship from the conclusions of theory, which arises from the theory's not embracing the whole of the circumstances attendant on a vessel's motion through the water. By recurring to the explanation which has been given of these circumstances in a previous portion of this article, some further elucidation may be afforded to the unsatisfactory result of the theory. When motion is communicated to a vessel from a state of rest, or from a lesser degree of motion, the effort of the wind on the sails is greater than that of the water on the hull, whether to propel the vessel in the direction HE of the keel, or, laterally, in the direction GH, and the velocity of the vessel in each of these directions is accelerated by the excess of the force of the wind over the resistance of the water, until, ultimately, by the diminution in the relative velocity of the wind, and the increase of the relative velocity of the water, an equilibrium ensues between the propelling and the resisting forces, and the vessel continues to move in the direction of the last acting force, and with the last acquired velocity. Now the resistances of the water in the direction EH and HG may be assumed to increase as the squares of the velocities, and from the nature of the form of a vessel, and from the comparative direct and lateral resisting areas, the resistance arising from form or area is much smaller in a direct than in a lateral direction, and therefore the equilibrium between the forces which act laterally may ensue before that between the forces which act directly; in which case the lateral motion of the vessel will become uniform before the direct motion, and consequently the ultimate course or direction of the vessel, when all the forces have arrived at a state of equilibrium, will approximate to that of the last acting force, that is, will more nearly coincide with the direction of the keel, and the angle of lee-way will be diminished. As this reasoning depends on the intensity of the force of the wind, the effect will vary as the cause; and the greater the force of the wind, and consequently the velocity of the ship, the greater must be the diminution of the angle of lee-way, that is, the angle of lee-way will, so far as it is affected by these considerations, vary inversely as the sine of the angle of incidence of the wind on the sail.

Romme.

Romme, in his *Traité du Navire*, differs from the opinions advanced by Bouguer; and though his reasoning on this subject is far from clear, his opinions are valuable, as he founds the conclusions at which he arrives, that the lee-way varies inversely as the square of the velocity, and that it increases with the obliquity of the sails to the keel, principally on observations and experiments on the actual performances of vessels; and these are the only means by which, as yet, we can hope to arrive at the solution of this problem. However, much further observation is necessary to afford sufficient data on which to found an approximation to the lee-way which a vessel makes. The general facts which influence it appear to be the greater or lesser angle of incidence of the wind on the sail, as the velocity of the ship is dependent on this; the angle of the inclination of the sails with the keel; the form of the vessel as it affects the ratio of the direct and lateral resistances; the form of the vessel as it affects the velocity; the stability as it affects the lateral resistances; the quantity of sail set; and the state of the sea.

Tables might be formed.

The distance which a ship falls to leeward of her course in any given time may generally be very easily ascertained; and it would not be a task of any great difficulty to form tables, from actual observation, for ships, under all the various circumstances which have been shown to affect the deviation of their course from the line of direction of the keel. In the open sea the quantity of lee-way made in any certain time may be easily ascertained by measuring the angle which the ship's wake makes with the line of the keel; then, if the distance run during the time for which the lee-way is to be observed be ascertained, as that distance is measured along the line of lee-way, the distance run in any period of time will be to the distance which the ship has fallen to leeward of her course during that time, as radius to the sine of the angle of lee-way. When a ship is in sight of land, the angle which the direction of the keel makes with the line of lee-way may be more correctly observed by means of a fixed object on the shore, whenever the state of the wind and sea may render an estimation of the lee-way desirable, that is, whenever the wind is sufficiently steady; as, of course, it is supposed that the angle formed by the direction of the wind with the line of the keel will remain constant during the whole time for which the distance fallen to leeward is to be ascertained. If, when the ship is either approaching or leaving the shore, her head be constantly kept to the same point of the compass, the ship's course will be along the line of lee-way; and as all things are supposed to remain constant during the time of the observation, this line will form a constant angle with the line of the keel, and therefore the point on the shore, which will have the same bearing from the ship as the line of lee-way, will remain at that bearing during the whole time in which the ship either approaches to or recedes from the shore. Consequently, if, when a ship either approaches to or recedes

Experiments which may be made.

from a shore, an object on the shore be observed which has a constant bearing from the ship, it must be in the direction of the line of lee-way, and therefore the angle which it makes with the direction of the keel will be the correct angle of lee-way; and then, as before, if the distance run in any time be taken as the radius, the distance which the ship has fallen to leeward of her course in that time will be equal to the sine of the angle of lee-way to a radius equal to the distance run by the vessel in the time assumed.

The actual quantity gained to windward in any given time may also be easily ascertained. The motion of the vessel through the water may be considered in four directions, and the velocity with which it advances in either of these directions determined.

The actual velocity of the ship, or the velocity along the line of lee-way, which may be called the oblique velocity, may be resolved into two; the direct velocity, or that estimated in the direction of the keel, and the lateral velocity, or that which is in a direction at right angles to the line of the keel; and contemporaneous with these is the velocity with which the ship gains to windward. Let AB (fig. 10) be the direction of the line of the keel of the vessel, and EF the direction of the yard, cutting that direction of the keel obliquely. Then, whatever may be the direction of the wind GH, the course of the vessel will be along some line HK, forming an angle KHB with the direction of the keel; then suppose HK on the line of lee-way to represent the velocity of the ship in that direction, from K draw KL perpendicular to HB, and cutting HB in L; then the velocity HK is equal to the two velocities HL and LK; and HL and LK will represent respectively the direct and lateral velocities of the vessel, in proportion to the oblique velocity HK; and if from the points H and K, HM be drawn perpendicular and KM parallel to the direction of the wind GH, MK will represent the velocity with which the ship has gained to windward in the time in which she has described the space HK. For the origin of the wind being supposed to be at an infinite distance from the vessel, as HM is drawn perpendicular to GH, the direction of the wind, it may be supposed equidistant in every point from the origin of the wind; and as the angle GHK is less than the angle GHM, the line HK is within the line HM; and therefore the point K is nearer the origin of the wind than the point H, by a quantity equal to the perpendicular distance KM, of the point K, from the line HM; or the ship has gained the distance MK to windward in running from H to K. It is evident that if HM coincided with HK, the ship would neither have gained to windward nor fallen to leeward; and that if HM fell within HK, the ship would have fallen to leeward. When the distance HK run by the vessel along the line of lee-way, and the angle of lee-way KHL, are known, the value of KM may be easily determined; for since the angles GHF, FHL, and LHK, are all known, and the line MH is drawn perpendicular to HG, their complement, the angle MHK, is known; therefore, as HMK is a right angle, HK is to KM as radius is to the sine of the angle KHM; or KM is the sine of the angle KHM, to a radius equal to the distance run by the vessel in the space of time in which the required distance to windward, KM, was to be gained. The only difficulties in the practical solution of this proposition are, to determine the direction HM, or the perpendicular to HG, the direction of the wind, and the value of the angle GHF; for when the vessel is in motion, unless the directions of the wind and of the course of the vessel coincide, that is, unless the vessel is before the wind, the direction of the wind as shown by the vane on board will not be its true direction; for, from the velocity of the vessel through the air, the vane is subject to a force acting upon it in a direction opposed to that of the course of the vessel, the effect of which may be considered the same as if the vane was at rest, and was acted upon by a current of air having a velocity equal to that of the vessel, but acting in an opposite direction; consequently the vane is acted upon by two forces, the one in the real direction of the wind, acting with a velocity equal to the velocity of the wind in that direction, and the other acting in a direction opposed to that of the course of the vessel, with a velocity equal to that of the vessel in its course; and therefore the direction of the vane will be the diagonal of the parallelogram of which the sides represent these two forces in quantity and direction. It is therefore evident that, all things else remaining the same, the greater the velocity of the vessel, the more will the direction of the wind, as shown by the vane, or the apparent wind, deviate from the actual direction of the wind, or the true wind; and as this deviation arises from the action of a force in a direction opposed to the motion of the vessel, or acting along the line of the course from the fore-part of the vessel towards the after-part, the apparent direction of the wind will in all cases head the vessel more than the true direction of the wind, and consequently the vessel will always appear to lie nearer the wind than she actually does.

True di
tion of
wind.

The true direction of the wind may be found if the velocity and direction of the vessel be known, and also the velocity and direction of the apparent wind, as the corresponding velocity and direction of the true wind will form the third side of a triangle, of which the three sides will be to each other as the three velocities; and as two of these are known, and include a known angle, that formed by the direction of the apparent wind with the course of the vessel, the third side, or the direction and velocity of the true wind, may be easily found. But as there is a difficulty in ascertaining the velocity of the apparent wind, the most easy way of determining the direction of the true wind will be by observing the arc through which the ship's head passes from close-hauled on one tack to close-hauled on the opposite tack. The bisection of this arc will, all things else remaining the same, give the direction of the true wind, as the course of the vessel, in relation to the direction of the wind, will be the same on either tack. Or the directions of the apparent wind may be observed both before and after tacking, and the true wind will be the middle point between the two directions, as the cause of the deviation of the direction of the vane from that of the true wind, or the velocity of the vessel, will be equal on each tack; and when the direction of the true wind is known, all the other parts of the triangle may be found, as the direction and velocity of the ship are known, and also the angle made by the apparent wind with that direction.

Should the velocity of the vessel be greater on one tack than on the other, it will be necessary, in order to determine the direction of the true wind, to divide the arc described by the vane when the ship is tacked into two segments, which shall be to each other in the inverse ratio of the velocities of the vessel on the tacks adjacent to these segments.

Writers on naval architecture and seamanship appear to have fixed the limit of the angle which is formed by the direction of the wind with the line of the keel, when a ship is close-hauled, at six points. This exceeds the angle which the writer of this article has repeatedly observed, by the means which have been described, as being formed by the direction of the wind with the line of the keel, on board the Acorn, one of the corvettes of the experimental squadron of the year 1827. The following table will show the results of some of the observations then made.

Ship's Head before Tacking.	Ship's Head after Tacking.	No. of Points difference.	State of the Wind.
S. S. E. ½ E.	W. ½ N	11	Fresh breeze.
W. by S. ½ S.	S. S. E. ½ E.	9	Light airs.
S. S. E. ½ E.	W. by S. ½ S.	9	Light airs.
W. ½ N.	N. by E. ¾ E.	9¼	Moderate.
N. W. by N.	E. by N.	10	Fresh breeze.
S. S. E.	W.	10	Very fresh.
W ½ S.	S. E. by S.	10½	Very fresh.

The second and third observations in this table were made on the same day. Their correctness receives farther confirmation from the circumstance, that when the Acorn was on the larboard tack, with her head W. by S. ½ S., the Columbine, another corvette of the squadron, was on the Acorn's beam, and it was ascertained from an observer on board the Columbine, she was lying about SE. by S. on the starboard tack; she must therefore have been lying as near the wind as the Acorn. The wind was very light, the rate by log being only one knot two fathoms; the angle of leeway, as observed by the wake, was seven degrees. It is desirable that similar observations should be made for all classes of ships; the circumstances of sea, wind, and rate by log, should also be noticed, that when any comparison is instituted, a due allowance may be made for their influence.

Li to the locity of ip.

We have seen that the velocity of the ship depends on the strength of the wind. Writers on naval architecture have advanced various opinions as to the practicable limit to the velocity of a ship, in comparison with that of the wind. Bouguer endeavours to prove that the velocity of a fast-sailing ship is, when going nearly before the wind, about $\frac{2}{7}$ths of the velocity of the wind, and that merchant-ships seldom attain to more than one fifth of its velocity; but he considers it not impossible that fast-sailing frigates may arrive at a velocity about equal to half that of the wind. Don Juan objects to Bouguer's limit, as too restricted; he corroborates the opinions he advances by the results which he has deduced from experiment and observation on the actual performances of ships. He says that fast-sailing vessels acquire a velocity nearly equal to that of the wind, even when going before the wind. The nearest approximation to this velocity which he observed was as twenty-one to twenty-three; the average conclusion at which he arrives is, that when the course of the ship and the direction of the wind nearly coincide, the velocity of the ship is from $\frac{2}{3}$ds to $\frac{20}{27}$ths of that of the wind.

Ma xceed tha the win

But in oblique courses it is very possible for the vessel to acquire a velocity even greater than that of the wind, if we admit the conclusions of Don Juan to be correct. The reason of this will appear evident on a very slight consideration. The velocity with which the wind acts on the sails after the ship has acquired motion is only its relative velocity, that is, the excess of its actual velocity above the velocity which the ship has acquired in the direction of the wind. Now, when the directions of the wind and of the course of the vessel coincide, this relative velocity of the wind is only the difference between the actual velocities of the wind and of the vessel; but when the course of the vessel is oblique to that of the wind, the relative velocity of the wind is the difference between the actual velocity of the wind and that part of the velocity of the vessel which can be resolved in the direction of the wind. Robison, in the article on Seamanship, says, that when the sails are square to the keel, and the wind right aft, the ship's velocity is in direct proportion to the relative velocity, and to the square root of the surface of the sails; therefore, he says, "in order to increase the relative velocity by an increase of sail only, we must make this increase of sail in the duplicate proportion of the increase of velocity."

When the sails are oblique to the keel, he says "the velocity of the ship is proportional to $\surd S \cdot V \cdot \sin. a$; that is, directly as the velocity of the wind, directly as the sine of the absolute inclination of the wind to the yard, and directly as the square root of the surface of the sails." This agrees with the conclusions that have been already drawn; and it is evident that, the velocity of the wind remaining the same, and the sine of the angle of inclination of the wind to the yard becoming equal to the radius, or if the whole force of the wind act in a direction perpendicular to the yard, the velocity of the ship will depend on the area of the sails set, and may therefore, even theoretically speaking, be increased without limit.

Rig of a vessel should be adapted to her form.

From all the conclusions which have been deduced in the course of these remarks on the mutual action of the wind and water on a ship, it appears evident that the degree of perfection in the performance of a ship, whether with reference to her motion round an axis of rotation, or to her course through the water, depends very greatly on the suitableness of the disposition and proportion of the sail to the form of the vessel. That there should be an analogy between these elements is evident; and experience and reason alike show, that the more nearly the rig of a ship is suited to the qualities of her form, the more nearly do her performances approach to perfection. Vessels which, from the proportions and form of their bodies, are capable of lying near the wind, and of maintaining a weatherly course, cannot evidently be made to develope these advantages of form to their full extent, unless their rig is also appropriate for rendering such qualities available; while vessels of which the form and proportions are not so adapted for sailing in oblique courses, by having a rig peculiarly adapted for such forms and courses, may even be unable to acquire the degree of advantage in these oblique courses that they would otherwise be capable of attaining, and at the same time fall far short of the velocity of which they might be capable in direct courses. In fact, in order that a ship may sail well, her form must not only be adapted for velocity and quickness of manœuvre, but her rig must be adapted to her form; and she must be commanded by an officer competent to develope the advantages of both form and rig.

The first of the following tables was compiled from a work, Scales of Displacements, &c. by Mr Parsons, a member of the late School of Naval Architecture. The second was formed by Mr Henwood, another member of the same establishment, and published by him in an article in the United Service Journal. The third was by Mr Fincham, the master shipwright of Her Majesty's dock-yard at Chatham, and published in the Papers on Naval Architecture.

These tables compose together a valuable analysis of some of the elements of construction of our ships of war, and, within their limits, cannot fail of proving useful to the naval architect; because, as we have before said, naval architecture is a science of comparisons and analogies. To the reader of the foregoing pages of this article it need scarcely be observed, that there yet remain many difficulties opposed to its being perfected, and that these can only be removed by a rigorous course of inductive investigation applied to the results of a patient, an attentive, and, above all, a competent comparison of the reported qualities and performances of ships, with an analysis of the elements of their design. When the School of Naval Architecture shall be re-established, as it most assuredly will be, the exercises of the students in their calculations, and their experiments on ships, may be made available to this end, by gradually obtaining the preliminary analysis of the whole navy of England; a work of very far too great labour for any thing but the combined endeavours of many individuals to accomplish; and when accomplished, of too vast extent, and of too varied and too conflicting results, to be grappled with by any but by a mind apt to conceive, to collate, and to generalize, and competent to submit these generalizations to the ordeal of strict mathematical investigation.

NOTE.—The depth of the lower side of the false keel, below the lower edge of the rabbet, for the brigs of eighteen guns, is not inserted in the table, as an additional false keel is put to these vessels when they are altered from brigs to ships, giving them an increase of six inches of false keel forward, and no increase aft. On this account the draught of water given for them in the table is measured from the upper side of the main keel.

Description of several Mechanical Methods of Designing the Body of a Ship.

Mechanical processes substituted for correct principles.

The following mechanical methods of designing the forms of midship sections, and of ships' bodies, have been published in different English and French works on naval architecture. Some of these are for forming the midship section alone; others are for deducing the successive sections forward and abaft from a given midship section. Such methods of endeavouring to compensate for the absence of more correct principles on which to found the design of a ship, were rendered necessary whenever the vessel to be built was of too large a size to admit of being conveniently put up by the aid of the eye alone; and consequently almost every merchant-builder is in possession of some such empirical system, to enable him to form a design for a ship. Whether the ship built after the design so formed, will prove to be possessed of good or of bad qualities, does not generally enter into the consideration, excepting in so far as the crude ideas of the inventor of the system may have guided him in forming it. We say the crude ideas, because the builder whose judgment is sound enough to enable him to arrange facts and classify observations, and whose experience has been extensive enough to have furnished him sufficient facts from which to deduce principles, will abandon all such attempts as futile, and will pursue the study of naval architecture in the manner in which alone it can be studied to certain advantage, that is, as an inductive science. His success will depend on his fitness for the task.

If all the principles which are involved in the design for a perfect ship were developed, and correct results could be obtained by calculation on every point involved, a system might be formed. A system might also be formed combining all the present knowledge on the subject; but this is far from desirable; it would necessarily be imperfect, and it would be entailing imperfection on the future.

Metho for for midshi section

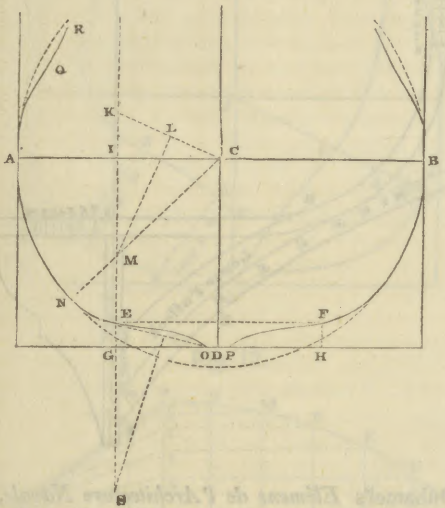
M. Bouguer, in his *Traité du Navire*, gives four methods which have been used for describing the midship sections of ships. He observes, that in these plans the midship sections are generally formed of arcs of circles; but that sometimes, through the ignorance of the inventors, of the fact, that for two arcs of circles to touch each other without cutting, their centres must be in the straight line which passes through their point of contact, the midship sections which they formed by these arcs had not even the advantage of being curves, but had angles in their contour. He shows how this error may be avoided. The first method he gives

anical
ods of
gning
lies.

B e
P Four-
ni

is that of Le Père Fournier. A straight line AB (fig. 11) is drawn, which he takes to represent the moulded breadth of the ship. A circle RANB, which has this line for the diameter, is then described; and, bisecting AB in C, he draws the perpendicular CD, equal to the depth intended to be given to the vessel, which extends from the under part of the beam to the upper side of the keel. Through the point D he draws a line parallel to AB, and, making DG and DH each equal to half the flat of the floor, equal also, if so determined, to one fourth of the whole breadth, he draws the verticals GE and HF equal to the rising of the floor. These may be assumed equal to the twenty-fourth, the eighteenth, or the twelfth part of GH. He then finds on GE, produced both ways to K and S, a point M, which he takes for the centre of an arc of a circle NE, that touches the first circle in some point N, and the straight line EF in E. Then with a point S assumed as a centre he describes the arc EO, which, touching the straight line EF or the arc NE in E, meets the side of the keel in O. He has thus ANEO for the form of half the section, and the other side is drawn in the same manner.

Fig. 11.



Bo er's
cor tion.

Bouguer corrects this method thus: He takes EK equal to the radius CA of the first circle, or equal to half the length of the beam, and having joined the points K and C by the straight line CK, if it be bisected in L, and LM be drawn perpendicular to it, the intersection of this perpendicular with EK will be the centre M of the arc NE. For MC being equal to MK, and EK having been made equal to AC or to NC, it is evident that MN will be equal to ME, and consequently the arc of the circle described from the point M as a centre, and which will pass through the point E, will touch the first circle in N. To determine the other centre S, bisect the straight line EO, and from the point of bisection draw a perpendicular which will meet IG produced in the point S, which will be the centre of the arc EO. The arcs AQ and QR are described, the first round the point I as a centre with the radius IA; the second round any assumed centre with a radius equal to AI.

By de
Pal

Another method is for determining the midship sections of flat-floored ships. It was invented by M. de Palmi of Brest. A rectangle ABIL (fig. 12) is described, which has for its breadth the breadth of beam, and for its height the depth to the keel. At E and F, the extremities of the flat of the floor, the perpendiculars GE and HF are drawn equal to the rising. A line KE (fig. 13) equal to LG is assumed, and a square described upon it; two quadrants of circles AQE and AXE are inscribed in this square, and either arc AXE is divided into a certain number of equal parts, AV, VX, XY, YZ, &c. drawing from the points of division VO, XN, &c. perpendicular to the radius AK. The depth of the vessel to the rising of the floor is divided into the same number of equal parts; and transferring to level lines drawn through these last points of division O, N, &c. the distances OS, NR, MQ, &c. intercepted in fig. 13 between the radius AK and the arc of the circle AQE, it only remains to pass a curve ASRQPE, in fig. 12, through the extremities of all the perpendiculars or ordinates OS, NR, &c. and the form of half the first section is obtained. ED may be formed by an arc of a circle touching the first curve E, and joining the side of the keel at D.

Mechanical
Methods of
designing
Bodies.

Fig. 12.

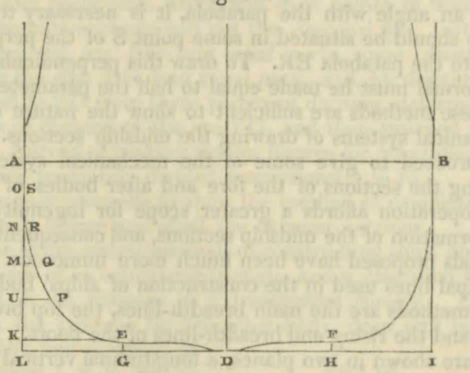


Fig. 13.

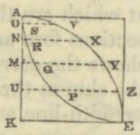
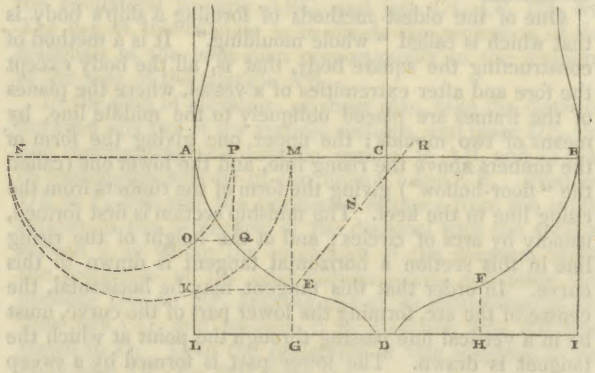


By Bouguer.

A third method, given by Bouguer, is for sharp ships. Form as before the rectangle ABIL (fig. 14), circumscribing the part of the section below the main breadth AB; then the rising GE or HF of the midship-floor is taken equal to a fifth or a sixth part of the flat of the floor GH. The points E and F being determined, two portions of parabolas AE and BF are described, A being the vertex and AC the axis of the one, and B the vertex and BC the axis of the other. The flat of the floor is formed by two arcs of circles, the convexity of the upper arc being below, and of the lower arc above. Having drawn from the point E, EK and EM perpendicular respectively to AL and AC, describe from a centre in AC produced indefinitely towards N, the semicircle MKN passing through the points K and M. Then AN will be the parameter of the parabola, which will serve to determine as many points in the curve as may be desired. If it be required to find a point in the vertical line PQ through which the curve will pass, it may be found by describing the semicircle NOP, and drawing from the point O, where the semicircle cuts AL, the horizontal line OQ, the point Q, the intersection of this line with PQ, will be a point in the parabola. In the same manner any number of points may be found. In order that the first arc of

Fig. 14.



Mechanical Methods of designing Bodies.

the circle of which the flat of the floor is formed, may not make an angle with the parabola, it is necessary that its centre should be situated in some point S of the perpendicular to the parabola ER. To draw this perpendicular, the sub-normal must be made equal to half the parameter AN.

Methods for forming the body.

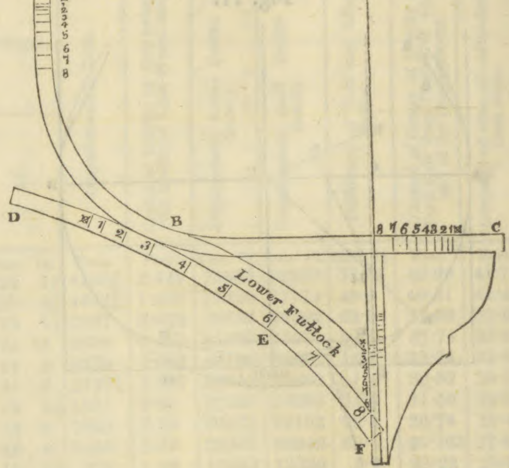
These methods are sufficient to show the nature of the mechanical systems of drawing the midship sections. We will proceed to give some of the mechanical systems of forming the sections of the fore and after bodies of ships. This operation affords a greater scope for ingenuity than the formation of the midship sections, and consequently the methods proposed have been much more numerous. The principal lines used in the construction of ships' bodies by these methods are the main breadth-lines, the top breadth-lines, and the rising and breadth-lines of the floors. These lines are shown in two planes, a longitudinal vertical plane, and a longitudinal horizontal plane. The rising of the main breadth-line shows the projection on the longitudinal vertical plane of the heights above the upper side of the keel, at which are the greatest breadths of the different vertical sections fore and aft; and the horizontal main breadth-line shows the corresponding distances from the middle line of the ship at the respective sections. The rising of the top breadth-line, and the horizontal top breadth-line, show in the same manner the heights from the upper side of the keel, and the horizontal distances from the middle line of the ship, of the different vertical sections at the top breadth of the timbers. At these heights, and at these distances from the middle line, arcs of circles are generally described, which give the form of parts of the vertical sections, or of the frames of the ship. The rising line of the floors gives in the same manner the heights above the upper side of the keel, and the horizontal breadth-line of the floors gives the distances from the middle line at which the floor-sweeps commence.

Whole moulding.

One of the oldest methods of forming a ship's body is that which is called "whole moulding." It is a method of constructing the square body, that is, all the body except the fore and after extremities of a vessel, where the planes of the frames are placed obliquely to the middle line, by means of two moulds; the upper one giving the form of the timbers above the rising line, and the lower one (called the "floor-hollow") giving the form of the timbers from the rising line to the keel. The midship section is first formed, usually by arcs of circles; and at the height of the rising line in this section a horizontal tangent is drawn to this curve. In order that this tangent may be horizontal, the centre of the arc, forming the lower part of the curve, must be in a vertical line passing through the point at which the tangent is drawn. The lower part is formed by a sweep which reconciles with the upper curve. Usually this sweep does not correctly touch the upper curve, although the inaccuracy is not very important in this method of construction. In forming the body-plan, the heights of the main breadth and rising lines at the different frames are set off, and the different sections drawn by the two moulds. On the horizontal part of the upper mould ABC (fig. 15) are marked the half main breadths of the different sections, as shown at C, and on the upper part of the mould their heights, as at A; the lower mould DEF is also marked where it meets the side of the keel at the different sections.

In moulding any timber, a square, called the rising square, with the heights of the different risings of the timbers marked on it, is used, by which the moulds are set according to the particular timber the form of which it is intended to obtain. On this square are also frequently marked the heights of the cutting down, by which the form of the inside of the timber is obtained at the same time. The operation of moulding a timber may be best seen by reference to the figure, where the moulds and rising square are set for moulding the lower futtock. No. 8

Fig. 15.



Method Duhame

In Duhamel's *Elémens de l'Architecture Navale*, there is a French method, nearly resembling this, of "whole moulding."

By Mun Murray.

In Mungo Murray's Treatise on Ship-building, a method is given for forming a ship's body by the use of the sector. This instrument is formed of two scales connected by a hinge, so as to open and shut like a common rule. Seven lines are drawn on each leg of the sector from its centre, divided at numerous points, indicating lengths which refer to differents elements of the body. The marks on the corresponding lines on the two legs of the sector refer to the same distances.

The lines on one side of the sector are divided for the fore-body, and on the other for the after-body. The manner of using these lines is thus described. "The general dimensions being determined, and a scale adapted to the drawing, take the half breadth with a pair of compasses, and placing one foot in the proper point for the half breadth of the midship section, which is shown on one of the lines, open the sector till the other foot reaches to the same point in the corresponding line on the other leg."

The sector being thus set, the different distances are taken by the compasses from the corresponding points marked on the corresponding lines, and set off in the different plans.

It is immediately evident that, by the use of the sector as described, all ships constructed by it would be similar to that according to which the distances were marked on these lines. If it is required to form a fuller or a sharper body than that by which the lines of the sector were divided, the midship section, with the foremost and aftermost sections, must be determined agreeably to the will of the constructor; and the intermediate sections will be determined on the diagonals by setting the sector separately for each diagonal, and then taking the distances from the lines as before for the formation of the different plans in the drawing.

By Bouguer.

The next method of constructing ships' bodies which we shall give is described by Bouguer; the diagonals in this method are formed of arcs of ellipses. The midship section is formed at will, and the extreme sections, forward and abaft, are formed in an arbitrary relation to the midship section. To form the after-body by this method, let ABC (fig 16) represent the midship section, FED the after section, and BE the projection of one of the diagonals. Describe the arc of a circle BA (fig. 17) whose radius is equal to three times the line BE (fig. 16), and whose versed sine BC is equal to BE. Divide the sine AC into any

Fig. 16.

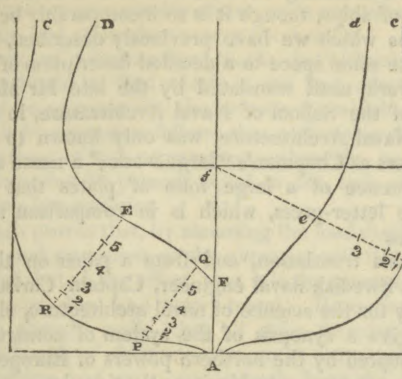


Fig. 17.

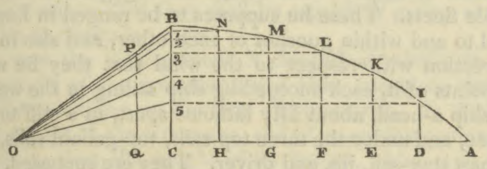
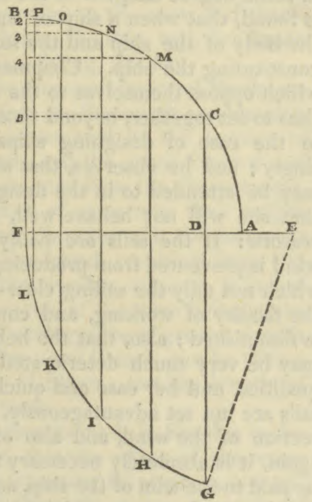


number of equal parts, according to the number of intermediate timbers it is intended to draw. From these points of division draw the lines DI, EK, &c. perpendicular to AC; and from the points where these lines intersect the arc of the circle draw I5, K4, &c. parallel to AC. Transfer the line BC, so divided at 1, 2, &c. to BE, in fig. 16, which will give points in which the intermediate sections will cut the diagonal BE. The other diagonals are divided similarly by taking any point O in AC produced (fig. 17), and joining OB, OI, &c. and placing the projection of any diagonal as PQ parallel to BC, and with its extreme points in OB and OC. Some constructors prefer dividing each diagonal separately, by describing arcs of circles BA with different radii; others, instead of dividing the sine AC into equal parts, divide the arc AB into equal parts, and then proceed as before.

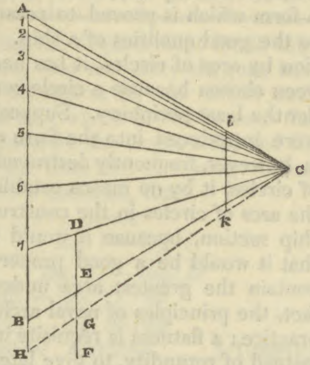
Fig. 18.



The fore-body is formed by nearly the same means, but is always made fuller than the after-body. Let *Abc* (fig. 16) represent the midship section, and *Aed* the extreme section forward; produce the projection of the diagonal *be* to meet the middle line of the body-plan in *f*. Describe the quadrant of a circle BA (fig. 18) with a radius equal to *fb* (fig. 16), and draw the sine DC equal to *fe*, and parallel to FB. From a point E in FA produced, describe an arc of a circle, with a radius equal to once and a half or twice FB, according as it is intended to make the fore-body fuller or sharper, meeting CD produced in G. Divide the arc FG into as many equal parts as it is required to find spots on the diagonal *be*, for the intermediate sections; and from the points of division H, I, &c., draw HM, IN, &c. parallel to BF; and draw P1, O2, &c. parallel to FA. Then transfer BF, so divided, at 1, 2, &c. to *bf* in the body-plan, which will give points in which the intermediate sections will cut the diagonal *bf*. Instead of dividing the arc FG into equal parts, some constructors divide the sine DG into equal parts, and, by drawing lines parallel to FD from these points of division, determine the points of division of the arc FG, and then proceed as before. Instead of making similar figures for other diagonals, they are frequently divided proportionally to *fb*.

Bouguer proceeds to show the method of completing the diagonals before and abaft the extreme sections.

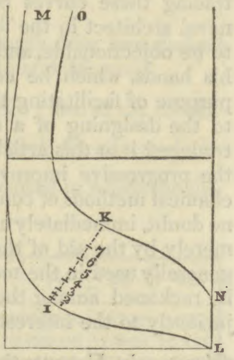
Fig. 19.



One of the easiest methods of constructing ships' bodies, is by means of an equilateral triangle, and is described by Duhamel in his *Elémens de l'Architecture Navale.* To construct the triangle for the after-body, draw any line AB (fig. 19), and divide it at the points 1, 2, 3, &c. so that the distance from 1 to 2 may be three times the distance A1, taken at pleasure, the distance from 2 to 3 five times A1, and so on; the number of points of division corresponding to the number of intermediate sections between the midship section and the stern-post, together with the after-section at the stern-post. Suppose the number of intermediate sections to be 7, let the distance from 7 to B be at least equal to the distance between the vertical sections on the plan of elevation. Describe on AB the equilateral triangle ABC, and join C1, C2, C3, &c. The use of this triangle is to divide the projection of the diagonals in the body-plan proportionally to the divisions of the base of the triangle AB.

In the plan of elevation, or sheer plan, take the distance between any two of the vertical sections, and place DE, the line representing this distance, parallel to AB, and so that its extremities may be in the lines C7 and CB. Produce DE to F, and take the horizontal distance from the intersection of the projection of the diagonal with the vertical section 7, to where the projection of the diagonal meets the projection of the after fashion-piece; and place this distance DG on DF, keeping one of its extremities in D; then join CG, and produce it to meet the base AB produced in H. Take the projection of this diagonal in the body-plan IK (fig. 20) from the midship section LIM to the fashion-piece NKO, and place it in the triangle parallel to the base AB, and with its extremities *i* and *k* in CA and CH; the lines C1, C2, C3, &c. will divide the line *ik* proportionally to the divisions of the base of the triangle AB. Transfer this line so divided to its place in the body-plan: the points 1, 2, 3, &c. will give spots through which the intermediate vertical sections will pass.

Fig. 20.



Some who have used this method of forming ships' bodies placed the projections of all the diagonals parallel to the base of the triangle; others placed them at different angles with the base. Duhamel recommends their being placed as follows. The projection of the lower diagonal representing the floor ribband parallel to the base; the projection of the second diagonal at an angle of

Chapman's Parabolic System.

60° 30′ with that part of the side of the triangle above the projection of the diagonal; the third at an angle of 68°; the fourth at an angle of 86°; the fifth at an angle of 65°; and the projection of the sixth or top-breadth ribband at an angle of 60°.

To construct the fore-body, a nearly similar process is adopted; but the base of the triangle is differently divided,—generally in a geometrical progression whose common multiplier is 2. The divisions of the bases of the triangles, however, are altogether arbitrary, as well as the angles of inclination at which the projections of the diagonals are placed, for both the fore and after bodies.

Objections to the use of such processes.

These are some of the most esteemed mechanical methods of constructing the midship sections of ships, and the fore and after bodies in relation to them. The inspection of them already shows that there is no attempt to describe a form which is proved to possess any property conducive to the good qualities of a ship. In forming a midship section by arcs of circles, it has been said that this figure has been chosen because a circle contains the greatest area under the least periphery. Supposing even that this principle were introduced into the form of a midship section, which is, however, frequently destroyed by the use of several arcs of circles, it by no means establishes the propriety of using the arcs of circles in the construction of the form of a midship section, because it would first be necessary to show that it would be a good property for a midship section to contain the greatest area under the least periphery. In fact, the principles of naval architecture require a contrary practice; a flatness is requisite in some parts of this section instead of rotundity, to give lateral resistance, great stability under a given area, and fine water-lines. The use of the ellipse is equally arbitrary. Little can be said in favour of either of the methods of designing bodies which we have described, nor need any thing be urged against them: it will evidently be perceived, that they are the resources of persons who are called upon to give designs of ships, and who, being ignorant of any correct data on which to form their design, are necessitated to adopt some such system of construction that they may designate as their theory. In no case do we find that those who have published systems such as the foregoing, attempt to prove that ships built after these systems are in consequence good ships; the utmost assumption appears to be, that by proceeding with a drawing after the course laid down, the result will be the design for the body of a ship. All such methods are to be deprecated, as being mere empirical substitutes for knowledge, and because they not only oppose a barrier to legitimate attempts towards improvement, but they actually prevent the application of such knowledge to the designing of ships' bodies, as may really be possessed. If we look upon systems for tracing these curves merely as aids to the well-informed naval architect in the formation of his drawing, they cease to be objectionable, and become mere mechanical means in his hands, which he can use or vary at pleasure, for the purpose of facilitating the mechanical operations incidental to the designing of a ship. They are also necessarily introduced into this article, as forming an essential feature in the progressive improvement of naval architecture. Mechanical methods of constructing designs for bodies followed, no doubt, immediately upon the method of constructing them merely by the aid of the eye, and they continue to be very generally used in the merchant-service, and may, no doubt, be reckoned among the causes which have operated so injuriously to the interests of our mercantile navy.

Chapman's Exponential and Parabolic Systems of Construction.

Chapma Parabol System

Chapman work trans lated in Papers on Nava Architec ture.

These were described in the last work of the celebrated Swedish naval architect Chapman; it was published in 1806. The parabolic system must be classed in this division of our subject, as among the mechanical methods of designing the forms of ships, though it is so incomparably beyond all those plans which we have previously described, that we shall devote some space to a detailed description of it. The Swedish work, until translated by the late Mr Morgan, a member of the School of Naval Architecture, in the Papers on Naval Architecture, was only known to English ship-builders as Chapman's "large work;" a name acquired in consequence of a large folio of plates that accompanies the letter-press, which is in comparison not very voluminous.

From this translation, and from a paper on the same work by a Swedish naval engineer, Captain Carlsund, unfortunately for the science of naval architecture, also dead, we shall give a synopsis of the system of construction at present adopted by the northern powers of Europe.

Criterio of the qu lities of ships.

Chapman commences his investigation by assuming a case, which he presumes may be taken as a criterion of the qualities of ships. This case is an engagement between hostile fleets. These he supposes to be ranged in lines parallel to and within gunshot of each other, and also in such a direction with respect to the wind that they lie within six points of it, each succeeding ship sailing in the wake of the ship a-head, about fifty fathoms apart, in a stiff top-sail breeze, and under the three top-sails, top-gallant sails, fore-topmast stay-sail, jib, and driver. They are supposed, when under these circumstances, not to incline more than seven degrees, and must be capable of fighting their leeward lower-deck guns with a heavy sea running; be good sailers, and work well to windward; so that although the ships may be of different sizes, and carry different weights of metal, yet, in equally high winds, and under similar sail, their angles of inclination being nearly the same, their guns may be worked with equal convenience, they may be all equally efficient in point of velocity, and under all circumstances manœuvre with equal facility. Chapman then says, of two hostile fleets opposed to each other, the fleet which is composed of the stiffest and best-sailing ships is master of the attack, and can begin and end it at pleasure. But that, as the operations of many such ships together, although of different sizes, should at once produce the same effect as if they constituted but one machine, it is necessary that they should keep in company, and be effective in proportion to their size. As they must sail equally well, the area of their sails must be proportional to the resistance they experience from the water; and as all the guns must be used and worked with like advantage, their inclination must be nearly the same, so that the form of the ships below the water will be in some degree adapted to the same area of sails; hence it is found, that when a ship of the line is to be constructed, the body of the ship and the sails are to be considered as constituting the ship. Chapman points out the difficulties which oppose themselves to the designing bodies which are thus to act together, beyond those which present themselves in the case of designing ships intended to sail and act singly; and he observes, that although all the rules of art may be attended to in the design of a ship, it may happen that she will not behave well, and this for the following reasons: If the sails are badly cut and made, so that the wind is prevented from producing its full effect on them, by which not only the sailing close-hauled is injured, but also, the facility of working, and consequently of manœuvring, is diminished; also, that the behaviour of a ship under sail may be very much deteriorated as regards her weatherly qualities, and her ease and quickness of working, if all the sails are not set advantageously, both in respect to the direction of the wind, and also of the ship's course. And, again, it is absolutely necessary that great attention should be paid to the trim of the ship, and to the adjustment of the positions of the masts, which have a great effect on a ship's qualities. Such, he says, are the reasons why it so frequent-

Ships an sails to b considere together.

Trim of t ship.

C man's bolic tem.

ly happens, that a ship may in one voyage possess very bad, and in another very good qualities, or at one time be a very bad sailer, and at another a very good sailer.

The natural inference from this is, that although the form of a ship should be that which is the best adapted for all that may be necessary to the service for which she is intended, it by no means follows that such a ship shall realize the intentions of her constructor, unless she be equipped and commanded by persons equal to the task of properly developing her qualities.

E omy to ve la ships an eavy m l.

He then proves that, by assuming the load displacements, the crew and provisions as the expense, and the weight of a round of shot as the effect, that it is the greatest economy to have large ships and heavy metal. Repeating the observation already made, that all ships forming a line-of-battle, although of different sizes, must act as parts of the same machine, and must consequently have the same qualities, which cannot be effected if the ships be similar, it follows that the rules by which they are designed must be of such a nature that they shall be capable of giving similar qualities to dissimilar ships.

Di ace- me de- pe ent on ar ment.

He says the displacement is dependent wholly on the total weight of the armament, and then considers the various items making up the total displacement. It consists of the weight of the armament, and of every thing connected with it; then the weight of the ballast, which is in proportion to the armament.

Ba st.

Ballast, he says, is necessary for a ship of the line, in order to preserve its qualities at the end of a long voyage, when the greater part of the provisions and ammunition will have been consumed. Also, as these weights are so considerable that the ship may be lightened to such an extent that her centre of gravity may not only rise a foot higher above the water from this diminished immersion than it was at the commencement of the cruise, but will rise so much the more from the influence this diminution of the weights in the hold will have in elevating its position, the stability is also necessarily diminished. It is therefore proper, in order that this loss of stability may not be too great, to have such a quantity of ballast that the remaining weight in the hold may not be too little in relation to the constant weight above the water. And also, he says that the consideration that a ship necessarily lightens from the consumption of stores, renders it necessary that all the calculations which relate to her stability should be made in relation to a water-line, assumed as that which she would have after the expiration of about a quarter of the cruise; and it should be from this water-line that the masts, &c. should be determined.

The next component of the displacement consists of the provisions, which are in proportion to the crew, and therefore to the armament; and, lastly, the ship, with her masts, yards, rigging, anchors, cables, fitting, &c. &c.

Le h and bre h.

Having determined the displacement required for the armament, the next considerations are the length and breadth. These have hitherto been determined by the number of ports, the space between them, and the space forward and aft; but they should be determined from the displacement, for the product of the number of guns into their weight determines the displacement, therefore the displacement determines the length. If the length resulting from this be considered too great for the number of ports, it is because the sum-total of the weights of the guns being given and constant, it follows that if each gun be of greater weight of metal, the number is smaller; and if each gun be of less weight of metal, the number is larger; but the length of the ship is nevertheless the same.

Res nce.

It appears that, from experiments made in Sweden in the year 1794, it was determined that the effect of the water on the after-end of a body, in opposing its progress, is a minimum when the surface of the body makes an angle of 13° 17′ with its middle line, and that consequently Chapman designed the after-bodies of his ships in accordance with this result.

Chapman's Parabolic System.

General rule for length and breadth.

In order to form general rules, according to the exponential system, for deducing the length and the breadth from the displacement, he proceeded in the following manner. The greatest breadth at the water-line for all line-of-battle ships is called B; and the length of the "construction water-line," which term will be afterwards explained, is called *l*. Then, he says, "designs of two classes of ships composing the line-of-battle were constructed with great care, and the following table formed."

	110	94	66
Displacement, D.............. ... =	152875	128297	88722
Length, *l*.......................... =	207·59	196·65	175·48
Breadth, B......................... =	56·27	53·32	48·46

In finding the length *l* from the displacement for all ships of the line, the ships of ninety-four and sixty-six guns have been used. Put therefore $128297 = \mathrm{D}$, and $88722 = D$, also $196{\cdot}65 = \mathrm{l}$ and $175{\cdot}48 = l$, where it will be seen that the Roman characters are used for the larger ship, and the Italic for the smaller. Then from the foregoing reasoning the following proportion is deduced, that

$$\mathrm{D}^{\mathrm{v}} : D^{v} :: \mathrm{l} : l; \text{ hence}$$

$$\text{the exponent } v = \frac{\log.\ \mathrm{l} - \log.\ l}{\log.\ \mathrm{D} - \log.\ D}$$

$$= \frac{\log.\ 196{\cdot}65 - \log.\ 175{\cdot}48}{\log.\ 128297 - \log.\ 88722}$$

196·65..................2·2936940   128297.........5·1082165

175·48..................2·2442276   88722..........4·9480313

0·0494664   0·1601852

$$\frac{0{\cdot}0494664}{0.1601852} = 0{\cdot}3088 = v$$

2·2936940

5·1082165×0·3088 = 1·5774172

0·7162768...5·2033 = the co-efficient.

2·2442276

4·9480313×0·3088 = 1·5279520...5·2033 = the co-efficient.

Thus the length $l = 5{\cdot}2033\ \mathrm{D}^{0{\cdot}3088}$ is obtained for all the line-of-battle ships.

To find the breadth B from the length *l* for three-decked ships the same method is used. Thus, the exponent for 110 and 94 gun ships, $v = \dfrac{\log.\ 56{\cdot}27 - \log.\ 53{\cdot}32}{\log.\ 207{\cdot}59 - \log.\ 196{\cdot}65} = 0{\cdot}9947$; and as the co-efficient is found to be a divisor $= 3{\cdot}5863$, the breadth B for all three-decked ships of the line $= \dfrac{l^{0{\cdot}9947}}{3{\cdot}5863}$.

To find the breadth B from the length *l* for two-decked ships. The exponent v of ships of 94 and 66 guns, $= \dfrac{\log.\ 53{\cdot}32 - \log.\ 48{\cdot}46}{\log.\ 196{\cdot}65 - \log.\ 175{\cdot}48} = 0{\cdot}8391$; and as the co-efficient is a divisor $= 1{\cdot}5767$, the breadth B for all two-decked ships of the line $= \dfrac{l^{0{\cdot}8391}}{1{\cdot}5767}$; according to which the following table is calculated.

	110	94	80	74	66	52
Displacement, D =	152875	128297	107400	96422	88722	66753
Length, *l*..........=	207·59	196·65	186·15	180·05	175·48	160·72
Breadth, B.........=	56·27	53·32	50·92	49·51	48·46	45·01

Having explained the method of determining the principal dimensions, we shall refer for a description of the parabolic system of construction to the paper we have already

Chapman's Parabolic System.

mentioned as having been written by a Swedish naval engineer, Captain, then Lieutenant Carslund. It says,

Whether sections of ships follow a general law.

Curve of sections.

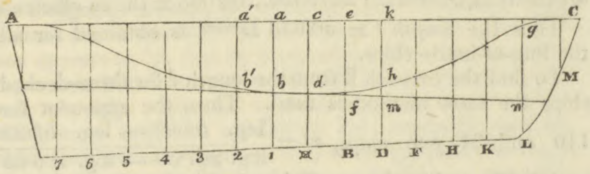
Chapman endeavoured to discover whether or not the areas of the several transverse sections in well-constructed ships followed any law; and if so, to find that law. For this purpose he calculated the areas of the sections of several ships; and in order to make the numbers more convenient, he divided these areas by the breadth of the midship section; then, at their respective stations on the drawing, setting off from the water-line, distances equal to the quotients, he traced a curve representing the areas. This curve he called the curve of sections. He then endeavoured to find the equation to the curve, or rather that of another curve which would coincide with this for the greatest length; and he found, that if the power and parameter of a parabola were so determined as to allow that curve to pass through three given points of the curve of sections, the two curves would nearly coincide. In the fore-body the three points were taken; one forward, one at the midship section, and one midway between. In the after-body the points were similarly situated. In some ships the exponent to the curve was higher in the after-body than in the fore-body, in some it was the same for both. It was also found that there were ships in which the curve of sections almost exactly agreed with the parabola, and these ships invariably bore excellent characters. Chapman consequently concluded, that if the areas of the several sections of a ship were made to follow the law of the abscissas of a parabola, a vessel possessing good sailing qualities might be formed, and the process of construction much simplified.

This account shows that the method is applicable to all sorts of constructions, as it only requires that the relative areas of the sections shall decrease from the midship section towards the extremities in a certain relation, which can be varied to infinity; it is therefore equally useful in constructing the sharpest man-of-war as the fullest merchant-man.

To construct the curve of sections.

Suppose a ship is found to answer well at some given water-line, AC (fig. 21). Let the areas of the transverse vertical sections be divided by some constant quantity, as, for instance, the breadth; and suppose the distances *ab*, *cd*, &c. equal to the quotients, to be set off on the respective sections from the water-line; then a curve drawn through the points *b*, *d*, &c. will be the curve of sections. It will be found to be convex to the water-line at the extremities.

Fig. 21.



The order of the parabola which coincides for the greatest distance with this line may easily be found.

To find the assimilating parabola.

Let the general equation to the parabola be expressed by $y^n = ax$; then it is always possible to determine n and a, so that the parabola shall pass through two points besides the vertex. Any two points between b and C may be taken, but it is evident that the farther apart the three points are taken, the longer will the parabola coincide with the line of sections. Of course, neither point may be in the convex part of the line of sections. It will be found that the point g at the foremost frame, and h in the middle between g and b, are the points which should be taken.

Draw a tangent to the curve at the point b, which will be parallel to the water-line; then mh and ng are abscissas, bm and bn ordinates to a parallel passing through b, h, and g; put $mh = x'$, $ng = x''$, $bm = y'$, and $bn = y''$; then, substituting these values in the equation to the parabola, we have

$$y'^n = ax', \text{ and } y''^n = ax'',$$

$$\text{or } n \log. y' = \log. a + \log. x', \text{ and}$$

$$n \log. y'' = \log. a + \log. x'';$$

$$\text{hence } n = \frac{\log. x' - \log. x''}{\log. y' - \log. y''}$$

$$a = \frac{y'^n}{x'},$$

$$\text{and } \log. a = \frac{\log. x' \cdot \log. y'' - \log. x'' \cdot \log. y'}{\log. y' - \log. y''}.$$

We have now the values of n and x, and by calculating several other abscissas, we can trace the parabolic curve. The same operation applied to the after-body will give the exponent and parameter of the parabola, which is the most similar to the curve of sections in that body.

It generally happens that the exponents are nearly the same in both bodies, if the place of the midship section be determined in the manner to be shown in the sequel.

It will be found that the parabola and the line of sections very nearly coincide, the former being sometimes a little within the latter between g and h, and without at the foreside of h, and sometimes, but much more seldom, the contrary. The parabola always cuts the water-line at a short distance from the rabbets, this distance being rather greater forward than abaft.

This sy tem app to Ame can ship

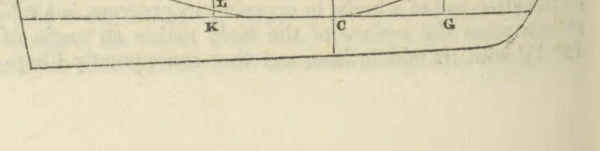
Several American ships of war have been submitted to this method of investigation, which was found to answer very well with their bodies. Indeed there can be no great deviation, as the parabola varies according to its exponent and parameter; if the ship is full, a large exponent adapts it to that shape; and if the ship is lean, a small one. If the body has a long straight of breadth, and sharpens quickly at the extremities, by deducting a part in midships from the comparison, the system may still be applied; or if, as is the case generally with English merchant-ships, there is a very great draught of water in proportion to the breadth, by deducting a part from the water-line downwards, this method may be applied to the remainder.

From this reasoning, it appears that ships may be constructed to coincide exactly with the parabolic line, without deviating from the forms which experience has proved to be the most conducive to giving ships good qualities. Chapman stated that this would most probably be superior to the old system, and the result has confirmed his statement; for ships of the line, frigates, and merchant-men have been constructed after it, all of which have been very fine vessels.

Displa ment.

From the manner in which the curve of sections is formed, it follows that its area multiplied by the breadth is equal to the displacement, and that the centre of gravity of the area is in the same transverse section as the centre of gravity of the body; but the area of this curve, supposing it to be a parabola of a certain power, is a known part of the rectangle formed by the greatest ordinate and the abscissa; hence, by making the areas of the sections decrease in the ratio of the abscissas in the parabola, we obtain certain equations between the quantities. To find these equations, suppose the parabolic line, now also representing the line of sections, to be ACB (fig. 22), cutting the water-

Fig. 22.



pman's abolic stem.

line at some distance from both rabbets; let C be the place of the midship section, and DC the greatest abscissa. Put $AB = l$ and $DC = d$, let the exponent of the parabola before and abaft $= n$, and the displacement $= D$; then the area of the parabolic line $BDACB = \frac{n}{n+1} \cdot l \cdot d$, and the displacement $\frac{n}{n+1}\, l \cdot d \cdot B$ (B representing the breadth); but $dB =$ area of the midship section; hence $\frac{n}{n+1} \cdot l \cdot$ (*area of midship section*) $= D$............(1).

ship ion be- middle ength.

Let E be the middle point of the water-line AB, which we may call the construction water-line, F the place of the centre of gravity in point of length; let ED, the distance the midship section is before the middle of the water-line, $= k$, and EF, the distance the centre of gravity is before the middle, $= a$. We will now determine the place of the midship section in reference to the situation of the centre of gravity F.

As BCD represents the displacement of the fore-body, and CDA that of the after-body, the moments of these two parts will give the common moment.

The centre of gravity of the parabolic area is at a distance from the abscissa DC

$$= \frac{n+1}{2n+4} \times \text{the ordinate DB},$$

and for the parabolic area DCA it

$$= \frac{n+1}{2n+4}\, DA.$$

The moment of DCB from the point E

$$= \left(k + \frac{n+1}{2n+4} \cdot DB\right) \cdot DCB,$$

and the moment of DCA from the same point

$$= \left(\frac{n+1}{2n+4} \cdot DA - k\right) DCA.$$

But the areas DCB and DCA are proportional to DB and DA, and the sum of the above moments $= EF \cdot BCA$, or $a \cdot l$, l representing the area; hence

$$al = \left(k + \frac{n+1}{2n+4}\, DB\right) DB - \left(\frac{n+1}{2n+4} \cdot DA - k\right) DA$$

$$= -\frac{n+1}{2n+4}\, (DA^2 - DB^2) + k\,(DB + DA)$$

$$= (DA + DB) \cdot \left(-\frac{n+1}{2n+4} \cdot (DA - DB) + k\right);$$

but $DA - DB = 2k$, and $DA + DB = l$; hence

$$al = lk \cdot \left(1 - \frac{n+1}{n+2}\right),$$

$$a = k \cdot \frac{1}{n+2},$$

$$\text{or } k = a \cdot (n+2) \text{............(2).}$$

That is, if the midship section DC is placed at such a distance k from the middle point of the construction water-line, the centre of gravity will be in the point F assigned to it.

These two equations (1 and 2) form the principal foundation of the parabolic method of construction. In the first equation, any quantity may be known by assigning values to the others; and in the second, by fixing a value for the distance of the centre of gravity before the middle, the place of the midship section will be known. Then, having by the first equation found the exponent of the parabola, any abscissa GH or KL may be calculated. Suppose, for instance, GH to be required; then in the first assigned equation $y^n = ax$, n is known; also y and x are known for a certain point B, through which the parabola passes; the value of y for this point is DB, and of x is DC. This gives

Chapman's Parabolic System.

$$a = \frac{DB^n}{DC}$$

$$= (\text{by cutting } DB = f)\, \frac{f^n}{d} \text{....(3).}$$

Now GH is easily determined in the above equation, by assigning a value to CG; if CG or any other ordinate is expressed by y', the corresponding abscissa $GH = x''$ is determined by the equation

$$x' = \frac{y'\,n}{a} \text{......(4).}$$

This equation is sufficient for calculating the areas of all the sections for the fore-body; and for those of the after-body we have the equation (3), in which, by substituting f for DA, we get the value of the parameter a' of the parabola of the after-body; and substituting this value for a in equation (4), and giving to y' any value CK, a corresponding abscissa LK is obtained. And in the same manner as many may be found as may be thought proper. It is evident that GH and LK must be subtracted from the largest ordinate DC, to give G'H and K'L, which represent the areas of the corresponding sections.

This method of first calculating the abscissas, and then subtracting them, may appear indirect, as the true lines G'H and K'L could have been obtained at once by transforming the equation of the parabolic line to another, beginning at the point D; but it would then have lost its simplicity, and the calculations would not have been easier than by this method. One thing may, however, be done, which is to substitute the area of the midship section instead of its quotient by the breadth, by which the whole areas of the other sections will be obtained, instead of the lines which represent them.

The principles of the parabolic method being now explained, it will be easily seen how very useful its application is to the comparison of all ships, whether they were constructed with or without reference to it.

Exponent of the line of sections.

By referring to equation (1), we find that the displacement, area of midship section, and the construction water-line, being known, the exponent of a parabola that coincides most nearly with the line of sections is easily found; and we shall have (putting M for the midship section) the value of

$$n = \frac{D}{lM - D} \text{........(a).}$$

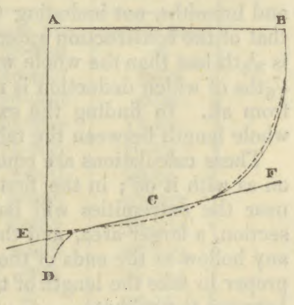
This value of n shows the degree of fulness of the ship.

The parabolic method may also be applied to show the relative fulness of the midship section, of any of the water-lines, of the displacement with respect to the water-line, and of several other elements.

Exponent of midship section.

Let ABC (fig. 23) represent a midship section, and let EF be a tangent to the curve at the point of contrary flexure C; the small area ECD not being of any importance, may be neglected. If the midship section is at all similar to those usually given to ships, a parabola may be assigned which shall pass through the points B and C, and have nearly the same area with the midship section, and also nearly coincide with the curve, so that the exponent will afford means of ascertaining its relative fulness.

Fig. 23.



Chapman's Parabolic System.

Call the breadth of the water-line AB $= \frac{1}{2}$B, the depth AE $= h$, and the area ABE $= \frac{1}{2}$M, and let m be the exponent of a parabola having the same area; then

Exponent of the midship section.

$$\frac{m}{m+1} \cdot \tfrac{1}{2}\mathrm{B} \cdot h = \tfrac{1}{2}\mathrm{M},$$

$$\text{and } m = \frac{\frac{1}{2}\mathrm{M}}{\frac{1}{2}\mathrm{B}h - \frac{1}{2}\mathrm{M}} = \frac{\mathrm{M}}{\mathrm{B}h - \mathrm{M}} \ldots\ldots\ldots(5).$$

In the same manner, the exponent may be found for the water-line, by supposing a parabola with its vertex as the greatest breadth, and passing through the points in which the water-line cuts the middle line. Suppose the exponent of this parabola $= r$, the length on the water-line $=$ L, and, as before, the breadth $=$ B; also let the area of the water-line $=$ W; then

Exponent of the water-section.

$$\frac{r}{r+1} \cdot \mathrm{L} \cdot \tfrac{1}{2}\mathrm{B} \cdot = \tfrac{1}{2}\,\mathrm{W},$$

$$\text{and } r = \frac{\mathrm{W}}{\mathrm{BL} - \mathrm{W}} \ldots\ldots\ldots(6).$$

Lastly, suppose the areas of the several water-lines, from the load water-line downwards, to decrease in the proportion of the abscissas to a parabola; and let the exponent $= s$, the depth from the water-line to the tangent of the midship section $= h$, the displacement $=$ D, and the area of the water-line $=$ W; then

Exponent of the displacement.

$$\frac{s}{s+1} \cdot \mathrm{W}h = \mathrm{D},$$

$$\text{and } s = \frac{\mathrm{D}}{h\mathrm{W} - \mathrm{D}} \ldots\ldots\ldots(7).$$

By calculating these different exponents for ships already built, and which have been found to possess good qualities, a very correct idea of their shape will be obtained, which, in making new constructions, may be referred to; and after a very short practice the constructor will be enabled to determine, not only the principal dimensions, but the outlines of the body, before a drawing is begun.

Values of these several exponents.

A collection of such calculations was begun by Chapman, and has since his time been considerably augmented. We now therefore know what the value of the exponents ought to be in the different classes of ships, for the services to which they are destined. It is always found that large ships are fuller than small ones, and in consequence have larger exponents; and that merchant-men have larger exponents than men-of-war of equal size.

The exponent of the line of sections in the Swedish navy, in ships of the line, varies from 2·5 to 2·7; of the midship section, from 5 to 3·8; of the water-line, from 6·6 to 5·9; and of the displacement, from 2·2 to 1·8; of course the larger exponent belongs to the larger class of ships.

In frigates, sloops, and brigs, they are smaller; the exponent of the line of sections varies from 2·3 to 2·1; of the midship section, from 3 to 1·9; of the water-line, from 5·2 to 3·25; and of the displacement, from 1·6 to 1·25. These exponents show that small ships have much larger dimensions in proportion to their displacements than large ones.

The above results were obtained from the displacements and breadths, not including the plank; and the length is that of the construction water-line, which, in Swedish ships, is $\frac{1}{84}$th less than the whole water-line between the rabbets, $\frac{7}{10}$ths of which deduction is made from forward, and $\frac{3}{10}$ths from aft. In finding the exponent for the water-line, its whole length between the rabbets is taken.

These calculations are equally applicable with the plank on as with it off; in the first-mentioned case, the sections near the extremities will have, relatively to the midship section, a larger area, and there will therefore be scarcely any hollow at the ends of the curves, and it will not be improper to take the length of the water-line the whole length between the rabbets.

Chapma Parabo Systen

The following tables are given as an illustration of this method, in its application to English ships.

	Length on the Water-line.	Breadth, extreme.	Depth from the Water-line to the lower edge of the Rabbet.	Displacement, including the Plank.	Area of the Load Water-section.	Area of the Midship Section.
	Feet.	Feet.	Feet.	Cub. Feet.	Sq. Feet.	Sq. Feet.
Nelson.....	203·3	53·5	23·5	165182	10027	1099
Bulwark...	180·3	49·0	19·8	105584	7706	791
Endymion	157·0	41·9	16·0	55807	5656	510

Then from the equations (a), (5), (6), and (7), the following results may be obtained:—

Applica of the s tem to E lish ship

	Value of n, the Exponent of the Line of Sections.	Value of m, the Exponent of the Midship Sections.	Value of r, the Exponent of the Water-line.	Value of s, the Exponent of the Displacement.
Nelson..........	2·836	6·9447	11·8034	2·3445
Bulwark........	2·851	4·4141	6·8273	2·2538
Endymion......	2·300	3·1795	5·1235	1·6088

From this table of exponents we may judge with certainty of the shape of the vessels. The Nelson, for instance, has a very full midship section, and an exceedingly full water-line; but she is not relatively so full towards the extremities as the Bulwark, and her displacement is not relatively much fuller than that of the Bulwark. The Bulwark has a small midship section, is full towards the extremities, and has a very large water-section in proportion to her displacement. The Endymion is a very sharp ship of her class, has a small midship section, is rather clean towards the extremities, but her water-line is not very sharp; its proportion to her displacement is very large.

The four exponents which have been described will, separately, only show the degrees of fulness in one direction; but they may be combined in such a manner as to express at the same time the longitudinal and transversal fulness; to effect which the value of the area of the midship section $= \frac{m}{m+1} \cdot \mathrm{B}h$ must be substituted in equation (1), which gives

$$\frac{n}{n+1} \cdot \frac{m}{m+1} \cdot l \cdot \mathrm{B} \cdot h = \mathrm{D} \ldots\ldots\ldots(b);$$

also, by substituting the value of W $= \frac{r}{r+1}$ BL in equation (7), we have

$$\frac{r}{r+1} \cdot \frac{s}{s+1} \cdot \mathrm{L} \cdot \mathrm{B} \cdot h = \mathrm{D} \ldots\ldots\ldots(c).$$

In these equations the products $\frac{n}{n+1} \cdot \frac{m}{m+1} \cdot \frac{r}{r+1} \cdot \frac{s}{s+1}$ show the relative fulness of the different ships in comparison to the circumscribing parallelopiped. When the construction water-line is equal to the whole water-line, as was supposed in calculating the foregoing table,

$$\frac{n}{n+1} \cdot \frac{m}{m+1} = \frac{r}{r+1} \cdot \frac{s}{s+1}$$

By this equation any error in determining the exponents may be detected; and also by using the whole equations (b) and (c), errors in the dimensions or exponents will be detected.

Methods interpola tion for finding other ele ments.

By a method of interpolation, formulæ of very easy application have been deduced; by which the depth of the centre of gravity of the displacement below the water-section, the height of the metacentre, and several other essential elements, may be approximated to without the usually long calculations; and thus most of the qualities of a ship which are determinable by calculation may be ascertained, Ch an's Pa olic S em.

compared, and altered, with very little trouble, before the construction is begun.

Ap ation of me- tho pra e.

In order to apply this method of construction to practice, nothing more is requisite than to know the limits between which the exponents generally are for the class of ships in question, the proportion between the principal dimensions, and the distance the centre of gravity should be before the middle of the load water-line. In Swedish ships of the line and frigates, the distance of the centre of gravity of the displacement before the middle of the load water-line is between $\frac{1}{70}$th and $\frac{1}{80}$th of the length, and in smaller vessels it is a little more, depending on the manner in which their stores and rigging are distributed. This distance being determined, the weight the ship is to carry, the weight of the hull, and the relative proportions of the different dimensions, or the value of the exponents, the calculations will give the areas of every section, leaving the constructor the power of giving them whatever form he may wish.

Ex ple of its lica- tio

Captain Carlsund was employed in this country in building steam-boats for the Swedish post-office service. He has given the calculations of one of these boats, which were all constructed on Chapman's parabolic system, as an example of its practical application.

Suppose the ratio of the breadth to the length to be α, and that of the breadth to the depth to be β; by substituting them in the equation (b), it will become

$$\frac{n}{n+1}\cdot\frac{m}{m+1}\cdot\alpha\cdot\beta\cdot B^3 = D.$$

The values of m and n are known, being assumed from former experience; the displacement is determined by the weight of the engines, added to the weight of the stores, &c. and an approximation to the weight of the hull. By assigning values to α and β, the value of B is obtained, and from that the values of the length and depth. The dimensions being now known, the scantling may be determined, and the true weight of the hull estimated; which, if very different from the approximation which was used, will cause a corresponding alteration in the dimensions, &c. With a steam-boat the stability is of minor importance, therefore it is not necessary to refer to equation (c).

The vessel in question was intended for two twenty-five horse-power engines, the weight of which, with the necessary stores, and the other articles, was estimated to be about 2050 cubic feet of water, and the approximation which was at first made to the hull was 1850 cubic feet, which supposed the whole displacement to be 3900 feet.

The vessel was intended to be sharp both at the midship section and at the extremities; hence n was taken $= 2·12$, and $m = 3·0$; the proportion between the length and the breadth, or α, was taken $= 5·25$; and that between the breadth and the depth, or β, $= 0·32$. By substituting this value in the equation, we have

Chapman's Parabolic System.

$$B = \sqrt[3]{\frac{3900\times 3·12\times 4}{2·12\times 3\times 5·25\times 0·32}} = 16·58.$$

$$\text{Length} = 5·25\,B = 87·04,$$
$$\text{Breadth} = 0·32\,B = 5·31.$$

By calculating the weight of the hull according to these dimensions, it was found that the approximation was too small by 175 cubic feet. By adding this quantity to the displacement, and retaining the other values, it will be found, from the above equation, that the

$$\text{Breadth} = 16·822,$$
$$\text{Length} = 5·25\times 16·882 = 88·315,$$
$$\text{Depth} = 0·32\times 16·882 = 5·383.$$

The weight of the engine, its situation, and that of its centre of gravity, must determine the place of the centre of gravity of the vessel, which was found to be about 2·25 feet before the middle of the length on the construction water-line; and consequently, from equation (2), the situation of the midship section was determined to be 9·27 feet before the middle of the construction water-line.

The stations of the other sections were determined by the room and space. The parameters for the fore and after bodies were first determined by substitution in the equation (3). In the fore-body

$$f = \frac{l}{2} - k = \frac{88·315}{2} - 9·27 = 34·887,$$

and in the after-body

$$f = \frac{l}{2} + k = 53·427.$$

The area of the midship section, from equation (5),

$$= \frac{m}{m+1}\,Bh = \tfrac{3}{4}\times 16·822\times 5·383,$$
$$= 67·912 \text{ square feet},$$

and the half area $= 33·956$.

Hence, by equation (3), the parameter of the fore-body

$$= \frac{\overline{34·887}|^{2·12}}{33·956} = 54·895;$$

and for the after-body,

$$a' = \frac{\overline{53·427}|^{2·12}}{33·956} = 135·499.$$

The calculations for the sections are contained in the following table.

For the Fore-body, $x\,\frac{y^{2·12}}{54·895}$.			
Sections.		Abscissa, or x.	Half the Midship Section, $-\,x$.
Name.	Distance from the Midship Sect. or y.		
	Feet.	Square Feet.	Square Feet.
End	34·89	33·960	·0
x	32·24	28·730	5·23
u	30·	24·660	9·30
q	24·	15·360	18·60
m	18·	8·349	25·611
h	12·	3·535	30·425
d	6·	·813	33·147
Midship section.	0·	·0	33·96

For the After-body, $x = \frac{y^{2·12}}{135·499}$.			
Sections.		Abscissa, or x.	Half the Midship Section, $-\,x$.
Name.	Distance from the Midship Sect. or y.		
	Feet.	Square Feet.	Square Feet.
End	53·43	33·960	·0
34	50·76	30·460	3·50
32	48·	27·060	6·90
28	42·	20·390	13·57
24	36·	14·700	19·26
20	30·	9·990	23·95
16	24·	6·225	27·735
12	18·	3·382	30·578
8	12·	1·432	32·528
4	6·	·329	33·631
Midship section.	0·	·0	33·96

The areas of the sections being thus determined, the construction of the draught was begun. The midship section, and one or two sections in each body, being drawn in, and their areas ascertained to agree with the tables, one or two diagonals were got in, and the rest of the sections drawn, always keeping their areas precisely equal to those given by the table. The direction of the diagonals at the extremities determined the places of the rabbets of the stem and stern-post, and from these the length of the whole load water-line was found to be 0·44 feet longer than that of the construction water-line; that is, 0·33 at the fore-end, and 0·11 at the after-end; consequently the length of the load water-line between the rabbets was equal to 88·755 feet.

As, in a ship constructed according to this method, the situation of the centre of gravity with respect to the length, and also the displacement, are known correctly, during the progress of the work much tedious arithmetical calculation is avoided; and, after a very little practice, it will be found that the forms of the different sections may with great ease be drawn to contain the requisite areas; consequently, by the general adoption of the method, an amazing saving of time and trouble would be effected.

There can be no doubt that this parabolic system offers great advantages, especially to the student of naval architecture, in the great facility with which it may be applied to institute comparisons between ships by means of the exponents. The mere repetition of the digits which number the displacement of a ship, or the area of either of her sections, will convey no idea of the form either of the body or of the section. Again, the ratio of the displacement, or of the area of the section, to that of the circumscribing parallelopiped or rectangle, will convey a scarcely more definite idea of shape; whereas the exponent of the displacement or of the section, presenting itself to us not only as an arithmetical measure of quantity, but referring us at the same time to a geometrical line, the mind becomes immediately almost as conscious of the peculiarities of the form of the body or of the section as if a drawing of either were present before the eye. A very slight attention to the comparisons which have been drawn between the Nelson, Bulwark, and Endymion, by means of their exponents, will convince the reader of the advantage which the system possesses in this respect, and of the value in which an extensive digest of ships of various forms and qualities, calculated on this principle, would be held by naval architects. At the same time, it is quite evident that even the inventor, Chapman, would not have recommended the parabolic system as a total substitute for the more rigorous applications of science, but only as accessory to them. Also, the parabola affords facilities for variations in form, which may be almost said to leave the architect at perfect liberty in his design.

General Observations on the Physiology of Timber.

As we cannot, in the space allotted to this article, enter into a particular examination of the nature and qualities of the different varieties of timber used in building a ship, we must confine ourselves to such observations on the physiology of timber in general, as may be of practical application.

Durability of the royal navy.

Of the mercantile navy.

Timber, when forming a component part of the structure of a ship, is subjected to many deteriorating influences that have no analogies in other combinations of wood-work. Although particular instances may be quoted of ships which have resisted decay for long periods, the average durability of the royal navy is reported not to exceed fifteen years. This we consider now an unfavourable statement; but, in the wear, tear, and neglect incidental to the constant services of war, even this average must be considerably lowered. The duration of the mercantile navy is stated at a higher average; but it must be remembered that the merchant-ship is not necessarily maintained in such perfect repair as the ship of war; and also, that the system of insurance enables both merchant and shipowner to freight and to sail ships, of which Lloyd's books record a most fearful and a most astounding tale; a tale which proves, that the longer average durability of the mercantile navy is in part purchased at a most sinful expenditure of human life; an expenditure which no amount of insurance can compensate.

Occasi instan durabi

The occasional instances of lengthened durability in some ships of the royal navy tend to prove, that it may be possible much to increase the average, by insuring a combination of the same causes which, perhaps accidentally in these cases, produced this effect. That this is a most important consideration is evident; for if we knew how to insure to our ships the durability recorded of the Montague, we should diminish the expense of our navy by one half; while if we could insure to them that recorded of the Royal William, we should diminish the expense to one sixth!

Classi tion o cay o ber.

The deterioration and decay of ships may be advantageously considered under several distinct heads. One may include the decay to which timber is subject, in common with all organized matter, and which may be either hastened or retarded, according as destructive or preservative influences prevail; another may include the variety of decay to which the name of "dry rot" has been applied; and another may include that decay which appears to be not only prematurely, but unnaturally induced, dependent on the injudicious combination of destructive agents with the inorganical compounds of the timber.

Decay be acc rated retard

Deter ing in ences

Prese tive i ences

That large masses of timber in combination should be more subject to the deteriorating influences which tend to accelerate decay, is what we may be led to expect from analogy. All organization of which we have any knowledge, becomes eventually decomposed by the chemical action which takes place in its constituents. During the life and health of a plant, the various components acting under the influence of their common vitality, perform their several functions in accordance to the end of their original combination; but with the cessation of life that influence ceases, and the constituents of the organized structure assert their individual existence, and resume their original affinities. Some separate, some form new compounds, and others which the vital principle had retained in harmless combination now act energetically and destructively on each other; while the original mass, under the influence of these several causes, gradually deteriorates, and is eventually decomposed. This result may be accelerated or retarded by the presence or absence of those circumstances which are favourable or unfavourable to it. Temperature, moisture, the vicinity or remoteness of agents either destructive or preservative, all have great influence in promoting or retarding decomposition, principally in as far as they promote or retard the fermentative process, which appears to be the preliminary step towards the rapid decomposition of vegetable matter. A certain degree of moisture is necessary to induce this fermentation; but when the other circumstances that are favourable to the process exist, this moisture is always to be found even in the best-seasoned timber, in which, on the authority of Count Rumford, there still remains one fourth of its weight of water. This will be readily understood when it is remembered, that a very large portion of moisture is always contained in the atmosphere, to the influence of which the timber has been exposed. While moisture to a certain extent appears essential, a continued immersion, or perfect saturation, is inimical to this vegetable fermentation. Again, a moderate temperature, not so low as to induce congelation, nor so high as to cause evaporation of the moisture, appears to be favourable to it. The unavoidable dampness of the atmosphere in ships, and the difficulty of maintaining a free circulation of air, contribute much to the process of fermentation, and consequently to the destruction of the original structure of the fermenting mass, by the distribution of its several constituents, and its consequent decomposition.

The difficulty of maintaining a circulation of pure air in those portions of the vessel below the surface of the water might be removed by adapting the openings between the timbers of the frame to this purpose. Pure air might by their means be easily supplied to the lower part of the "between decks," or even to the hold, through pipes; and the foul, heated, and therefore rarefied air, would rush from the upper part of the between decks, or of the hold, through a second series of pipes. The writer of this article proposed a plan for effecting this to the Admiralty, on his return from a cruise in the experimental squadron of 1827. The same principle is adopted now, very generally, to ventilate manufactories and other large and closely-peopled buildings.

Oxy n.

Its ect.

Dec com nces wit he felli of the ber.

The most active agent in the work of the decomposition of timber is the oxygen which it contains, whether this decomposition be rapidly induced by fermentation, or is more slowly and gradually taking place under the influence of the law which renders decay the necessary consequence of organization. The oxygen, which, during the vitality of the plant, was held in harmless combination, is set free, and immediately begins to act upon the woody fibre of the felled timber, and induces a slow combustion, the effect of which is the evolution of carbonic acid gas, and the carbonization of the wood, by which the tenacity and adhesiveness of its several parts are gradually destroyed. Timber, therefore, begins to deteriorate and to decay from the moment of its being felled; and indeed a gradual diminution of its strength may be observed during the process of its seasoning, which only ends with its total decomposition. The hastening the seasoning process is, however, advantageous, by depriving the timber of the superabundant moisture, and of the juices, which might otherwise induce an unduly rapid decomposition.

Dry t.

Dist - tive rac- teris .

Deri ion of th term Fung

The decay of timber has been frequently classed under two heads, natural decay, and decay from dry rot. Probably there is not such a marked distinction between these two decomposing principles as might be imagined. Very frequently the decomposition of timber is attended with the apparently spontaneous vegetation of parasitical fungi; and, according to common acceptation, that species of decay which is accompanied by the vegetation of these fungi has received the appellation of dry rot. The term was applied to it in consequence, probably, of the peculiarity attending it, that the decomposed wood had become a dry friable mass without fibrous tenacity. Whether the seeds of these plants are lying dormant in the juices of the timber while in a state of life and health, and the vegetative principle in them becomes active only when decomposition has furnished them a nidus, or whether they are floating in the atmosphere, and vegetate whenever favourably placed, is a point not yet established.

Gene cause f this ay.

However this may be, as in general this peculiar decay may be traced to imperfectly seasoned materials, we consider it may fairly be supposed that the seeds of the fungi are contained in a fit state for vegetation in the juices of such timber; and although it sometimes occurs and spreads among seasoned timber, it appears previously necessary that damp should have renewed and revived the vegetating principle in the seeds, and fermentation and decomposition have provided them a nidus. They then flourish and acquire strength on the sustenance which they draw from the decomposed wood; and in the same manner, and with a similar deteriorating effect as the parasitical plants which sometimes vegetate on the living tree, these destroy the dead timber, by abstracting all but the earthy particles, which are left without fibrous texture.

Preve tives.

Dryness, cleanliness, a free circulation of air, or the entire exclusion of it, appear to be the best preservatives against, or checks to, vegetable decomposition; while damp accumulations, and a vitiated atmosphere, rapidly induce it.

Tende of dec ncreas to

If the foregoing statement of the principles on which the decomposition of timber depends be correct, it is evident that its tendency is progressive, and that the decay must rapidly spread, from the accumulation of the deteriorating influences. It is also evident that the only means to check undue decay is by a removal of the inciting causes; and that the only means to prevent it, is to guard against those circumstances which are most liable to induce it, and to avoid the use of those materials in which it is most easily induced.

Precautionary measures.

Unseasoned timber should never be used, and even the most seasoned timber should only be used when in a dry state. When kilning plank was first adopted, now upwards of a century ago, the planks, after being set to the form of the body, were taken off to dry; this, however, was unnecessary, kilned plank drying almost at the mouth of the kiln. All decayed and all diseased portions of the wood should be carefully removed, and also the whole of the sap or imperfect wood, which, from being more soft and spongy in texture than the spine, absorbs moisture more easily, and, being also more filled with the vegetating principle and the vegetable juices, is more liable to fermentation, and consequently to decomposition, and to the growth of the fungi.

Influence of extraneous substances.

Iron fastenings.

Cause of their destructive effect.

We shall now consider the premature decay of timber induced by the substances which are used in connection with it. Of these the iron for fastenings has by far the most injurious influence. This is probably owing to the great affinity which exists between that metal and oxygen, so that each fastening becomes an absorbent of oxygen, either from the atmosphere or from the wood which surrounds it, and which is again supplied from the atmosphere. The surface that is first subjected to this change is converted into the brown oxyde of iron, which may be termed a supersaturated oxyde, and parts with its superabundance of oxygen to the lamina of pure iron immediately beneath it, while the surface absorbs a fresh store of oxygen from the wood; and thus the process of oxidation goes on through successive laminæ of the iron, until the whole of its metallic nature is changed, and its utility as a fastening is destroyed, while it becomes a reservoir of oxygen, which acts evidently on the woody fibre around it, and, by carbonizing it, rapidly and effectually destroys its tenacity.

Constituents of oak timber.

Of teak.

Effect of iron on teak less injurious. It therefore may be used in teak.

Action of copper on oak.

In this view of the action of iron in accelerating the decomposition of timber, we may trace the reason why its effect varies so much in different woods. Mackonochie, in his admirable Prospectus, says that oak is found to contain a much smaller proportion of oily or resinous particles than many other kinds of wood; and that, besides the lignic acid which it has in common with them, it contains an acid peculiar to itself, called the gallic acid, and that, therefore, the quantity of oxygen in oak is very considerable; that, on the contrary, in teak it is much less, while in this wood the resinous particles are so abundant as to have procured the teak-tree a place amongst the terebinthinous plants. He argues, that the iron, which cannot easily be protected before being applied as a fastening, acquires a protecting covering from the oily or resinous juices of the wood, pressed from the abraded vessels in the action of driving. This coating, which cuts off its influence on the oxygen, will be more or less perfect, in proportion to the quantities of the protecting substances contained in the wood. He states, on the authority of the experience of the shipping built in India, and used in the India trade, that the average duration of an iron-fastened teak ship is thirty years; and consequently he argues that it is a misapplication of expense to use copper fastening with teak, as the additional advantage gained is not at all commensurate with the additional expense. But with oak the circumstances are different; the action of oak on copper is not near so destructive of its metallic structure as it is on iron; and, on the other hand, the re-action of the metal on the wood is not so destructive of its ligneous fibre. The oxyde of copper, which forms almost immediately on its coming in connection with the wood, is not a supersaturated oxyde, but the portion of oxygen it has absorbed is held in strong combination; and, consequently, instead of the process of oxidation continuing from lamina to lamina, as has been described to be the case in iron, the surface oxidation becomes a natural protection of the copper from the action of the wood, and of the wood from the action of the copper, equivalent to the resinous or oily coating which supervenes in the case of iron driven into teak.

Various means of preserving timber. Mackonochie.

With this view of the process of decomposition in timber, we have an insight into the *rationale* of the various means proposed for its preservation. Several writers on timber have more or less urged the foregoing principle. Mackonochie, in his Prospectus, has adopted this theory; and though his reasoning on the causes of decomposition is not given with his usual perspicuity, his deductions as to the means of prevention are perfectly free from this objection. He recommends, that whatever iron is used for fastening, a protecting coat of paint or some other substance should be interposed between the iron and the wood, to cut off, as far as possible, the connection between the metal and the woody fibre.

Use of paint.

Seasoning timber in the light.

He also recommends that, in seasoning timber, care should be taken to expose it to the light, which will have great influence in making it give out its oxygen. But as it must re-absorb oxygen in the night, and will at least be supplied with it from the atmosphere, the only effectual means is at once to expel it, and fill up its space with some other substance; for which purpose, he says, " oil presents itself as the fittest, its use in defending timber from the action of the weather having been long acknowledged and practised." He recommends the following process as an easy means of impregnating the timber with this or any other similar substance. The wood is to be placed in a steam-tight chamber, and subjected to the action of steam, by which the air and gases will be expelled both from the chamber and the timber. Then, by condensing the steam, and repeating the process until the whole of the elastic fluids are withdrawn from the wood, and the non-elastic converted into vapour, the wood becomes freed from them, and if plunged into oil, and subjected to the atmospheric pressure, the whole interior of the wood will be filled with the oil. Mackonochie asserts that he then has (6th August 1803) in daily use a steam-chamber on the above principle, capable of containing from twenty to thirty planks forty feet long, or a proportionate quantity of timber, in which, while the planks are steaming to render them flexible, they are impregnated with teak oil. He says the oil may easily be procured from the chips and saw-dust used for the fuel of the steam-boilers; for it has been ascertained that Malabar teak contains such a quantity of oleaginous or terebinthinous matter, that the chips from the timber and plank of a ship built of it will yield, by a proper process, a sufficient quantity of tar for all its own purposes, including the rigging; and that although oak-timber does not contain so much of these substances, the chips of the fir consumed in the royal navy would be more than sufficient to supply tar to saturate the oak.

Saturation with oil.

Means of effecting this.

Oil may be procured from refuse timber.

By M. Pallas, to mineralize it.

Mr Bill, to saturate it with asphaltum.

There have been numerous proposals to impregnate timber, in a greater or less degree, with foreign substances. In 1779 a proposal was made by a M. Pallas to mineralize timber by steeping it to saturation in a solution of green vitriol, and then precipitating the green vitriol by means of lime-water. A gentleman of the name of Bill, about the year 1822, produced some samples of timber of large scantling, impregnated throughout their substance, apparently, with asphaltum. The samples thus prepared were subjected to a trial of five years' duration in the dry-rot pit at Woolwich; and we have it on the authority of Mr Knowles, the able secretary to the late committee of surveyors of the navy, that they perfectly withstood the " fungus rot," while numerous unprepared specimens were destroyed in one fifth of the above time. Sir John Barrow, whose long experience and acknowledged talent render his opinions on all naval matters extremely valuable, recommends the kreosote from the distillation of tar, which, in the shape of a gas, will, he says, penetrate every part of the largest logs, " and render the wood almost as hard as iron, so hard as not easily to be worked." Another plan, that proposed by Mr Kyan, is to soak timber in a solution of corrosive sublimate. This, on the principle advocated in this article, would be effective in all cases where the saturation was complete and permanent. Where the application is only of the nature of a surface application, there does not appear to be any reason why the corrosive sublimate should preserve the interior of the timber, or have more effect on that part than any other surface applications, excepting that it would more certainly destroy any vegetative principle which might exist in that portion near the surface to which it could penetrate.

Mr Ky with co sive sub mate.

Mr K process

The rationale of Mr Kyan's process may be best understood by the following quotation from a lecture by Dr Birkbeck. " Aware of the established affinity of corrosive sublimate for this material (albumen), he applied that substance to solutions of vegetable matter, both acetous and saccharine, on which he was then operating, and in which albumen was a constituent, with a view to preserve them in a quiescent and incorruptible state; and obtaining a confirmation of his opinions by the fact, that during a period of three years, the acetous solution openly exposed to atmospheric air had not become putrid, nor had the saccharine decoction yielded to the vinous or acetous stages of fermentation, but were in a high state of preservation, he concluded that corrosive sublimate, by combination with albumen, was a protection against the natural changes of vegetable matter....He conceived, therefore, if albumen made a part of wood, the latter would be protected by converting that albumen into a compound of protochloride of mercury and albumen; and he proceeded to immerse pieces of wood in this solution, and obtained the same result as that which he had ascertained with regard to the vegetable decoctions." The writer of this article has seen most conclusive experiments as to the beneficial effect of " Kyanization," especially on the softer woods.

Numb less no trums been pr posed.

Innumerable nostrums have been recommended as surface applications for preventing the decay of timber. Knowles, in his work on the Preservation of the Navy, gives a list of twenty-nine, besides many others the components of which were kept secret by their projectors. There does not appear to be sufficient evidence to prove the decided advantage of any of these applications; on the contrary, unless the timber to which they are applied should be thoroughly seasoned, all coatings on it which prevent the progress of the seasoning process, and confine the vegetable juices, have been proved to be injurious. If timber be already well seasoned, the principal preventives to decay appear to be ventilation and the exclusion of damp; and with unseasoned timber the same means will accelerate the process of seasoning. Those means of preventing decay by saturation with some chemical agent, and thus altering the nature of the timber by a chemical action on its constituents, appear to be the most likely to produce decided results. The physician-general of the navy, Sir William Burnett, finding that the precipitate caused by the kyanization was soluble in salt water, has lately substituted for that process saturation with the chloride of zinc; the precipitate which this forms with the albumen being unaffected by the action of the salt water. The beneficial effect of this chloride is very decided, in those specimens which the writer has had an opportunity of examining.

Sir W Burne

Time felling ber.

There has been much controversy as to the proper season for felling timber, into which we cannot devote space to enter. The argument appears to be in favour of the greater durability of winter-felled timber. In fact, the controversy appears more to have arisen from a desire to prove that spring-felled timber was not unequal to winter-felled, than for the purpose of eliciting truth; the bark being more easily detached and more valuable from off a spring-felled than from off a winter-felled tree.

Laying Off.

General observations and definitions.—Laying off is delineating the form of a ship according to its actual dimensions, in order to supply the workmen with the exact shape and proper positions of the principal pieces of timber which compose the structure. If the floor be sufficiently spacious, the ship may be laid off in one length; if otherwise, the operation must be performed in two or more lengths, according to circumstances.

The principal plans of a ship are the sheer, body, and half-breadth plans.

1*st*, The sheer plan is a projection on a vertical longitudinal plane, dividing a ship into two equal parts. Plate CCCCL. fig. 24.

2*d*, The body plan is a projection, on an athwartship plane, of transverse vertical sections of the ship, which sections are square to the keel. Fig. 25.

3*d*, The half-breadth plan is a projection, on a horizontal plane, of various sections of the ship. Fig. 26.

The principal lines employed, as well in the construction of a draught, as in laying off a ship, are water-lines, level lines, diagonal lines, and buttock and bow lines.

1*st*, Water-lines, in the sheer plan, are straight lines drawn parallel to the surface of the water. In the half-breadth plan, the water-lines show the boundaries of the sections of the ship, at the corresponding heights in the sheer and body plans. Figs. 24, 25, 26.

2*d*, Level lines are similar to water-lines, except that they are drawn parallel to the keel instead of to the water. To avoid confusion, the level lines are omitted in the sheer draught, but they are drawn in Plates CCCCLI. and CCCCLII.

3*d*, Diagonal lines show the boundaries of various sections formed by planes which are oblique to the vertical longitudinal plane, and which intersect that plane in straight lines parallel to the keel. Plate CCCCL. figs. 25 and 26.

4*th*, Buttock and bow lines are the boundaries of vertical sections of the ship, parallel to the vertical longitudinal plane. See B. L., figs. 24, 25, 26.

The main-breadth line is the boundary of the widest part of the ship in each of the three plans. Plate CCCCL.

The top-breadth or top-timber line, in the sheer plan, is a line drawn to the sheer of the ship, fore and aft, at the height of the under side of the gunwale amidships; and the top-side line is a sheer line drawn above the top-timber line, at the extreme height of the side of the ship. Plate CCCCL.

The cutting-down line is a curve in the sheer plan which corresponds to the upper surface of the throats of the floors amidships, and to the under side of the keelson. Plate CCCCL.

Fore and after bodies. These combined constitute the whole of the ship. They are supposed to be separated by an imaginary athwartship section, at the widest part of the ship, called the midship section, or dead-flat.

Midship body, as sometimes used, applies to an indefinite length of the middle part of the length of a ship, including a portion of the fore and after bodies.

Square and cant bodies may be considered as subdivisions of the fore and after bodies. There is a square fore-body, a square after-body, a cant fore-body, and a cant after-body. In the square body the sides of the timbers are athwartship vertical planes, whereas in the cant body the sides of the timbers, although vertical, are not athwartship planes.

Laying Off.

Moulding and siding.

Moulding and Siding. These terms are nearly synonymous with thickness and breadth; observing that the moulding of a piece is the dimension of the side on which the mould is applied for determining its shape or curvature. For instance, the moulding of a beam is its depth or thickness; its siding is its fore and aft dimension, or breadth.

Room and space.

Room and space is a certain distance determined by the siding of two adjacent timbers, together with the openings between them; or it is the distance apart of the joints of the frame, as from A to B in the disposition of the timbers, or one half the distance apart of the stations B, D, F, &c. in the sheer plan. Plate CCCCL. fig. 24.

Shift.

Shift. This, in its general sense, refers to a certain arrangement among the component parts of a ship. Thus we speak of a shift of plank, a shift of dead-wood, meaning thereby the disposition of the buts of the timber or plank, both with respect to strength and economy. In a more limited sense, "shift" means the distance apart of two neighbouring buts or scarphs.

Bevellings.

The bevelling of a timber is the angle contained between two of its adjacent sides. Bevellings are either acute angles, right angles, or obtuse angles. These three separate cases are denominated under bevellings, square, and standing bevellings.

Sirmarks.

Sirmarks are certain stations marked on the moulds of the timbers at which the bevellings are applied. These sirmarks are denoted in the body plan by the various diagonals.

Description of the draught, consisting of the sheer, body, and half-breadth plans.—The principal dimensions of a ship are length, breadth, and depth. Connected with and dependent on these three dimensions, are three plans, named the sheer, half-breadth, and body plans. These combined constitute what is termed the draught of a ship. We purpose to describe them separately. Plate CCCCL.

Sheer plan.

1*st*, The sheer plan or elevation (fig. 24) is the representation of an imaginary longitudinal section, dividing the ship into two equal parts, by a vertical plane passing through the middle of the keel, stem, and stern-post. This section is bounded by the fore part of the knee of the head, under side of the keel or false keel, aft side of the rudder, rake of the stern, and the sheer of the upper part of the top-side.

Perpendiculars.

Besides this plan being a section of the ship amidships, showing the sheer of the decks, cutting-down line, stations of the masts, &c., on it are also projected, in lines perpendicular to the aforesaid longitudinal section, the ports, cat-head, head-rails, side counter-timber, quarter-gallery, main-breadth line, channels, dead-eyes, &c. From all this we see that the chief use of the sheer plan is to obtain heights and lengths; heights measured from the upper edge of the rabbet of the keel, and lengths measured from the after or the fore perpendicular. These perpendiculars, which define the length of the ship, are drawn in most ships of war at the ends of the lower or gun deck; the foremost perpendicular at the aft side of the rabbet of the stem, the aftermost at the foreside of the rabbet of the stern-post.

Profile.

Occasionally the interior fittings and accommodations are shown on the sheer plan, as the beams, magazines, store-rooms, well, pumps, capstans, cabins, and other minutiæ; but as these produce confusion by multiplying lines, it is usual to represent the interior economy of the ship on a separate plan, called the "profile," or plan of the inboard works.

Half-breadth plan.

2*d*, The half-breadth plan (fig. 26) principally shows the form of the ship, 1*st*, when cut by water-lines; 2*d*, by level lines; and, 3*d*, by diagonal lines. As before observed, the planes of these diagonal sections intersect the longitudinal plane of the ship, in straight lines parallel to the keel. Besides the above, the form of the decks, main-breadth and top-breadth lines, may be also delineated on the half-breadth plan; together with the projection of the planes of the fore and after cant timbers, which will be more particularly explained in the sequel.

Body plan.

3*d*, The body plan (fig. 25) is simply a representation of vertical transverse sections, before, at, and abaft the widest transverse section, which is termed "dead flat," and usually denoted by the symbol ⊕.

The sections in the body plan in the fore-body are distinguished by letters, A, B, C, &c., those in the after-body by figures, 1, 2, 3, &c., corresponding with the same letters and figures in the sheer and half-breadth plans. It must be understood, that the sections in the body on the right of the middle line represent the starboard fore-body, whilst those on the left of the middle line represent the larboard after-body, of the ship.

It is thus seen, that from the aforesaid three plans we may derive correct ideas of the form of a ship, which form is obtained

From the sheer plan,	by vertical fore and aft sections parallel to the vertical longitudinal plane, as seen by the buttock and bow lines;
From the body plan,	by athwartship vertical sections, square to the keel, and at right angles to the vertical longitudinal plane;
From the half-breadth plan,	1*st*, by water-lines, or by planes parallel to the water; 2*d*, by level lines, or by planes parallel to the keel; 3*d*, by diagonal lines, or by planes inclined at any angle to the horizon.

The reader will also perceive from the preceding remarks, that

The sheer plan	is a projection	on a vertical longitudinal plane;
The body plan		on a vertical athwartship plane;
The half-breadth plan		on a horizontal plane.

As before remarked, the three above-described plans constitute the draught of a ship. We shall presently see their mutual dependence on each other, so that any two being given, the third may be obtained.

Profile. **Disposition.** **Midship section.** **Scheme of scantlings.**

Besides the sheer draught, it is customary to furnish the architect with a profile of the inboard works before explained; the "disposition," or the appearance of the timbers which constitute the frame, showing the heads and heels, and general arrangement of the futtocks; the midship section, on which is described the moulding, or athwartship size of the timbers, the thickness of the exterior and interior planking, the connection of the beams to the side, the dimensions of the water-ways, shelf-pieces, the description and fastening of the knees, &c. These, together with a scheme of scantlings, which is a document containing the dimensions, and other particulars, of the principal pieces which enter into the construction of the fabric, constitute all the preparatory information required by the builder.

After these general observations, we shall now enter more in detail into the description of the draught of a ship; but as laying off and practical building are so intimately connected, that a perfect knowledge of the one cannot be attained without some acquaintance with the other, it becomes previously necessary to describe, in general terms, the method in which the timbers of a ship are combined and disposed, both in the square and cant bodies.

This constitutes another division of our subject.

Frame of a ship.

The timbers of a ship are combined together in assemblages which are technically called "frames;" these are put together in a certain predetermined order, depending on a variety of circumstances, as the size and form of the ship to be built, the nature and dimensions of the timber to be used, the skill and judgment of the architect employed. We will suppose each frame to consist of a floor crossing the dead-wood, a first futtock stepping against the dead-wood, a second futtock on the head of the floor, a third futtock on the head of the first futtock, a fourth futtock on the head of the second futtock, and, lastly, a top-timber on the head of the third futtock. The above arrangement accords with the old system of building.

Old system. **Short-ti ber fra**

An economical modification of the plan was introduced of late years, by diminishing the length, and therefore by increasing the number, of the timbers. Thus the long floors are abolished, and their place is substituted by shorter floors, called cross timbers. To the sides of these cross timbers, giving scarph to and projecting beyond them, are bolted and dowelled pieces, called half floors. The first futtock will then but on the head of the cross timber, the second futtock on the head of the half floor, the third futtock on the head of the first, the fourth on the head of the second, the fifth on the head of the third, the sixth on the head of the fourth, and the top-timber on the head of the fifth. Occasionally lengthening pieces are added to the upper timbers, when required by the conversion. See figs. 34, 35, 36.

Figure 49, Plate CCCCLVII., represents a disposition with the buts of the frame arranged like those of a shift of plank, there being three timbers between every two buts, while in the usual disposition there is only one timber between every two buts.

Joints. **Single timber.**

By reference to the disposition of the frame, Plate CCCCLIV., it is seen that the timbers are not in contact sideways, but are kept apart a certain distance; although, for the sake of simplicity in laying off, we suppose them to touch each other from the keel to the top-side. This imaginary junction of the futtocks of a frame is called the joint. The joints of the frames are, with one exception, equidistant. This exception is seen in fig. 24, Plate CCCCL., in which the distance between the joints 3 and (2) is greater than between the other joints. This variation is for the purpose of introducing an additional timber, called the "single timber," so that there will be five timbers in the space 3 (2), whereas there are only four timbers between the other joints. Hence the opening in question is called the five-fourth opening; and one frame, instead of consisting, like all the others, of two adjacent timbers, will consist of an assemblage of three timbers. The reason of the introduction of the single timber is, because the position of the various futtocks is reversed in the fore and after bodies, *i. e.* those which in the fore-body are on the fore side of the joint, are placed in the after-body on the aft side of the joint. Hence, were it not for the single timber breaking the shift of the heads and heels, we should have a series of two buts together, as two first-futtock heads, and so on. The timbers being square to the keel, the joints will obviously be represented in the sheer and half-breadth plans by straight lines square to the keel.

Square body. **Cant bo**

As before explained, these joints and their corresponding frames are distinguished in the fore-body by letters, as A, B, C, D, &c. and in the after-body by figures, as 1, 2, 3, 4, &c. Thus it is seen that the sides of the timbers already described are athwartship vertical planes. This arrangement, however, is departed from at the two extremities of the ship; for if the sides of the frames were athwartship, timber of much larger scantling would be required, which would be more costly, more liable to decay from converting older trees, and would be still farther objectionable, from the fastenings, which ought to be square to the curve, cutting the timbers more obliquely. To obviate these inconveniences, the timbers, in technical language, are "canted."

Square cant bod

It has been before explained, that the sides of square timbers are vertical planes; so also are those of cant timbers. Again, the intersection of the plane of the square timber with the vertical longitudinal plane of the ship, is a vertical straight line: the same remark is applicable to the cant-timber. Further, the plane of the square timber is at right angles to this longitudinal plane, whereas that of the cant timber is oblique to this plane. The subject of square and cant timbers has been explained by the following familiar illustration. Imagine the before-named vertical athwartship plane to be fixed at its intersection with the vertical longitudinal plane, but still allowed to revolve on the vertical line of intersection as an axis. It may be considered as a door on its hinges. When the door is wide open, in other words, when the plane stands athwartships, it represents a square timber; when the door is partially closed, or allowed to revolve on its hinges, it represents a cant timber. This imaginary revolution, of course, takes place forward in the fore-body and aft in the after-body. Thus, in the half-breadth plan, Plate CCCCL., AB, drawn perpendicular to the middle line of the ship, represents the joint of a square frame; but if it is made to revolve forward round the point A, till it comes into the position A*b*, it then represents the joint of a cant frame.

The draught of a ship.

We have now to explain the manner of drawing the various lines and sections of a ship, and of transferring them from one plan to another. For this purpose it will be convenient to imagine the draught complete, and in a general way to retrace the steps by which the completion was effected, by explaining the adaptation and correspondence of the three plans with each other. Below the upper edge of the rabbet of the keel are drawn the depth of the rabbet and the under sides of the main and false keels. At a distance apart, equal to the length of the ship, are drawn the foremost and aftermost perpendiculars, at right angles to the keel, and respectively intersecting the aft part of the rabbet of the stem, and the fore part of the rabbet of the stern-post, at the height of the lower deck. The stem and stern-post, together with their respective rabbets, are likewise delineated. From the calculation of the weight of the ship when fully equipped, as already explained, is determined the position of the upper or load water-line; the other water-lines are drawn at pleasure parallel to, and generally equidistant from, the load water-line. They are severally marked No. 1, 2, 3, 4, &c. (Plate CCCCL.), observing that they are characterized by the same figures in the body and half-breadth as in the sheer plan.

Keel.

Perpendiculars.

Stem and stern-post.

Load water-line.

Sheer of the decks.

The load water-line being drawn in the sheer draught, the height of the lower deck may be determined. It is to be observed, that a deck is delineated by three lines, the upper two of which are parallel to each other, and represent the thickness of the deck at the middle; the third or lower line denotes the under surface of the deck at the side of the ship. Supposing the height of the deck determined amidships, forward and aft; let these heights be set above the load water-line, and through the three spots thus obtained draw a segment of a circle; this curve defines the deck at the middle. To obtain the deck at the side, proceed as follows. Draw a straight line, equal in length to the breadth of the ship amidships, to the interior of the timbers. Perpendicular to and at the middle of this line, set off the round-up of the beam, through which point and the extremities of the line draw the segment of a circle, which will represent the round-up of all the beams. Draw a tangent to this curve at its middle point, which will evidently be parallel to the first-named line, or chord of the arc. Now, to obtain the round-down of the deck at any particular station, take the half-breadth of the ship at that station, and set off this half-breadth on the tangent from the middle of the curve. Next take the perpendicular distance (at right angles to the tangent) of the curve from the point last obtained, and set it off on the sheer plan at the corresponding station below the under side of the deck at the middle; the spot thus obtained is the deck at the side. By proceeding in a similar manner at other stations we obtain several spots through which a fair curve must be drawn, and thus is determined the under surface of the deck, or the upper surface of the beam at the side of the ship. In like manner are the other decks delineated, their height and round-up being known. At present, however, only the lower deck can be decided. Before the upper deck, quarter-deck and forecastle, and round-house, are drawn, it will be necessary to draw, in the sheer draught, the midship and side counter-timbers. We here remind the reader that we are alluding to a two-decked ship, whereas the sheer draught (Plate CCCCL.) represents a frigate, which has one fighting deck less than a line-of-battle ship.

Wing-transom.

As the heels of the stern or counter-timbers rest on and are connected to the wing-transom, this transom may be considered as the foundation of the stern. To draw the wing-transom, set up in the sheer plan, from the upper edge of the rabbet of the keel, the height of its intersection at the middle line of the ship with the fore part of the rabbet of the stern-post. At this point draw a horizontal line, below which draw a second horizontal line, at a distance from the former equal to the round-down of the transom. On the upper horizontal line set off the round-forward of the transom, which square down to the second horizontal line. Next join the last-named point and the point of intersection of the upper surface of the transom, with the fore part of the rabbet, and we thus obtain the after upper edge of the transom. It is to be understood that the method just described for drawing the wing-transom is only an approximation to truth: thus we have supposed the after upper edge of the transom a straight line, whereas in reality its projection is a curve; but as this description is sufficiently accurate for our present purpose, we shall reserve any further remarks on the subject until we explain the method of laying off the transoms.

Having drawn a line to represent the after upper edge of the wing-transom, the fore and after extremities of this line will be respectively the terminations of the after parts of the lower ends of the midship and side counter-timbers; but before these timbers are described, it will be necessary to make a few observations on the stern of a ship.

The stern.

If we imagine the stern to be cut by a vertical fore and aft plane, the after boundary of this section, above the wing-transom, will consist of the hollows of the lower and upper counters, and a straight line from the upper knuckle to the top of the side. Moreover, the stern has two curvatures, a round-up and a round-aft. The round-up is variable, whereas the round-aft (above the upper knuckle) is constant. The round-up of the stern gradually increases from the wing-transom to the taffrail; that is, the right aft rails, which include the tuck-rail, the lower counter, upper counter, foot-space, and breast-rails, have more and more curvature as they ascend. The round-aft of the stern, from the upper knuckle to the taffrail, is the same in equal breadths; in fact, the stern is a portion of a cylinder, and therefore all sections square to its axis, or square to the rake, which is parallel to its axis, are portions of the same circle.

Counter-timbers.

We may now proceed to draw in the midship counter-timber. The stations of the upper and lower knuckles being determined, draw a circular arc to the hollow of the upper counter; and from the lower knuckle to the intersection of the upper edge of the wing-transom with the fore part of the rabbet of the stern-post draw another curve to the hollow of the lower counter. From the upper knuckle draw a straight line to the rake of the stern, and we thus complete the projection of the midship counter-timber.

Side counter-timber.

To draw in the side counter-timber in the sheer plan. At the height of the upper knuckle of the midship counter-timber draw a horizontal line; at the distance of the round-down of the upper counter below this line draw another horizontal line, on which set off the round-forward of the upper counter square to the rake. The point thus obtained will be the upper knuckle at the side. In like manner is

Laying Off.

obtained the lower knuckle at the side. From the two knuckles draw in the hollow of the upper counter, and from the lower knuckle to the fore part of the after edge of the wing-transom draw in a curve for the hollow of the lower counter.

Now if the top-side had no "tumbling home," the side counter-timber above the upper knuckle would be parallel to the midship counter-timber; and further, in proportion as the "tumbling home" is great or small, so will the heads of these timbers approximate to or recede from each other.

To obtain a point for the head of the side counter-timber, it will be first necessary to draw the round-aft of the stern. Strike a straight line at pleasure, the length of which is equal to the breadth of the stern at the lower knuckle. At the middle of this line erect a perpendicular, and on it set off the round-aft of the stern; through this last point, and the extremities of the line, draw a circular arc, from which we may obtain the round-aft of the stern, square to its rake, at any breadth. For instance, to procure the round-aft at the head of the side counter-timber, set off the half breadth of the ship at that height from the middle of the chord of the arc; then take the distance of this point (square to the chord) from the circular arc; this distance is the round-aft required, which, when set off square to the midship counter-timber, determines the aft side of the side counter-timber at its head. We have now to obtain spots for drawing in this timber between the head and the upper knuckle.

Stern.

As before remarked, the stern above the upper knuckle is cylindrical, and as all sections of a cylinder parallel to its axis are bounded by straight lines, while those sections which are oblique to its axis are bounded by curves, it follows, that in the sheer plan the midship counter-timber, as explained above, is a straight line, while the side counter-timber is a curve.

Further, as all sections of a cylinder made by a plane square to its axis are circles, while those sections which are oblique to its axis are ellipses, it follows, that in the half-breadth plan the round-aft of a plane, which in the sheer plan is at right angles to the rake of the stern amidships, will be circular, while the round-aft in the half-breadth plan of all other planes will be elliptical.

Round-aft.

Bearing this in mind, we proceed to show the manner of obtaining the elliptical round-aft of the level line Q at the height of the upper knuckle *a* at the sides (Plate CCCCLIII. fig. 31). In the sheer plan, from the point *a* draw *ab* at right angles to the midship counter-timber produced. Project the point *a* in the sheer plan to the middle line of the half-breadth plan, as *e*. From *e* draw *ef* at right angles to the middle line, and on *ef* set off the half breadth of the ship at the lower knuckle. Draw *eg* equal to *ab*, and through *g* and *f* draw a circular arc *ghf*, the radius of which arc will be equal to half the diameter of the cylinder; then will *ghf* be the round-aft of the stern square to its rake. Again, in the half-breadth plan draw any number of lines W, X, parallel to the middle line, intersecting the round-aft *ghf* in the points *h* and *i*. Take the horizontal distances of *h* and *i* from *ef*, and set these distances off on the line *ab* from the point *a*. Through the points thus obtained on *ab* in the sheer plan, draw lines parallel to the rake of the stern. Square down the points of intersection of the last-named lines, with the level line Q, to the corresponding lines W and X in the half-breadth plan. Lastly, through the intersections thus obtained draw a curve, which will represent the elliptical round-aft of the stern when cut horizontally. Further, as all parallel sections of a cylinder are similar curves, we infer that the round-aft just obtained will serve for the round-aft of any number of level lines drawn above the upper knuckle.

Therefore draw level lines above the upper knuckle, at a distance of from two to three feet apart, both in the sheer and body plans. Run off these level lines in the half-breadth plan. Square down the intersections of each of these lines in the sheer plan, with the midship counter-timber, to the middle line of the half-breadth plan. From these points draw the horizontal round-aft of the stern, and the intersections of this round-aft with the corresponding level lines will be the terminations of the said level lines. Square up these terminations to the respective level lines in the sheer plan, and through these spots draw a curve, which will be the projection of the after edge of the side counter-timber.

Side co- ter-timbe

To represent the projection of the side counter-timber in the body plan, take the distances square from the middle line in the half-breadth plan of the termination of each level line, and transfer these distances to the corresponding level lines in the body plan; through the spots so obtained pass a curve, which will represent the required projection of the side counter-timber. (Plate CCCCLIII. fig. 33.)

Decks.

Following the previous directions, the decks above the lower deck may now be drawn.

Ports.

The joints of the frames are drawn perpendicular to the keel. The previous explanation on the frame-timbers of a ship renders any further remarks on this subject unnecessary. The ports are drawn to the sheer of the ship. Their number, size, and distance apart, of course, depend on the determined armament.

Breadth-lines.

The main-breadth, top-breadth, top-side, and other lines, have been already explained; and with respect to the channels, head-rails, and other details, our limits preclude the possibility of entering into a description. We must therefore conclude our account at present of the sheer plan by referring to Plate CCCCL., and proceed to a brief description of the body plan. Fig. 25 represents the body plan. A horizontal line is drawn for the upper edge of the keel. On this line three perpendiculars are raised, at a distance apart equal to half the moulded breadth of the ship. The middle of these three lines represents the middle line of the ship, or rather the projection of the vertical longitudinal plane which divides the ship into two equal parts. The other two lines are the boundaries of the ship at the widest part, or dead-flat, ⊕. The curves A, B, C, &c. in the fore-body, and 1, 2, 3, &c. in the after-body, represent vertical transverse sections of the ship, at the corresponding joints A, B, C, &c. 1, 2, 3, &c. in the sheer plan. It is to be understood that these sections correspond to the exterior surface of the timbers, on the supposition that the plank of the bottom and top-side is not yet on the ship.

Body pl

Buttock lines.

Independent of the joints of the frame, many other lines in the body plan originate in the sheer plan, as port-sill lines, top-breadth, top-side, water-lines, &c. We shall presently describe the manner of transferring them from the sheer to the body plan. But there are other lines which may be said to originate in the body plan. Among this class may be mentioned buttock, bow, and diagonal lines. Buttock lines are vertical lines drawn at discretion at any distance from and parallel to the middle line. They are marked Nos. 1, 2, 3, &c. Plate CCCCLII. The position of the diagonal lines drawn in the body plan is not, however, arbitrary, because it has reference to two considerations, the length of the timbers, and the station of the ribbands and harpins: thus those marked floor-head, first futtock-head, second futtock-head, &c. show the lengths of the floors and futtocks, together with the heights of their heads and heels above the keel; while those marked first sirmark, second sirmark, third sirmark, &c. show the heights and situations of the various harpins and ribbands, which are placed between the heads of the respective timbers, in order to give support to the ship whilst in frame. Fig. 30.

Diagona

Ribbands and harpins.

Half-breadth plan.

The half-breadth plan is in most draughts placed below the sheer plan, the stations being squared down to its middle line. (Plate CCCCL.). Occasionally, however, the upper edge of the keel in the sheer plan answers to the middle line of the half-breadth plan, as in Plates CCCCLI., CCCCLII., and CCCCLIII. This is generally the case in laying off, because the dimensions of the mould-loft floor would not admit of any other arrangement.

From the description of the draught we proceed to explain the manner of transferring the various lines from one plan to another.

Dia als.

To run off the diagonals in the half-breadth plan. From the point of intersection of the diagonal with the middle line in the body plan, take the distances of the intersection of every timber with the said diagonal, which distances set off on the corresponding timbers in the half-breadth plan. Through the points thus obtained pass a curve, which will represent a vertical projection of the diagonal on the half-breadth plan, not in its original position, but after it is supposed to revolve until it comes into a horizontal position. The axis of revolution is a fore and aft line parallel to the keel, being the intersection of the diagonal plane with the vertical longitudinal plane of the ship. It remains to explain the method of ending the diagonals; but before the process can be clearly understood, it will be necessary to enter into a brief explanation of the rabbets of the stem and stern-post.

Ra ets of the em, &c.

The upper part of the rabbet of the stem, and also of the stern-post, is an equilateral triangle, whose sides are equal to the thickness of the bottom plank, the middle of the rabbet being half the distance between the fore and after edges. But at the lower part of the stem, although the fore part of the rabbet remains fixed, yet the middle and the after edges vary considerably from their relative positions at the upper part.

This variation is technically termed the "opening of the rabbet," and it arises from the alteration of the form of the body. Thus, if we conceive the bow to be of the same shape above and below, no alteration would be required in the form of the rabbet. Again, if the bow were so sharp near the keel that its horizontal section becomes a fore and aft straight line, then the ends of the bottom plank should be cut off square, and therefore in the sheer plan the middle of the rabbet would coincide with the fore edge. Hence we see that the middle of the rabbet approximates to or recedes from the fore edge, according to the sharpness or fulness of the lower part of the bow. In general, it will be sufficiently accurate for all practical purposes to place the middle of the rabbet at the lower part one third its breadth from the fore edge, from which point it gradually recedes from the fore edge till it arrives at the upper end of the stem, where, as before observed, it is midway between the fore and after edges.

The same remarks obviously apply to the rabbets of the stern-post and keel; observing, that with respect to the keel, the rabbet amidships is an equilateral triangle, the middle of which is equidistant between its upper and lower edges, whereas forward and abaft, the projection of the middle of the rabbet of the keel, in the sheer plan, with respect to the lower edge of the rabbet, partakes of a similar variation, as before described with respect to the rabbet of the stem. In general it should be understood, that that form of rabbet is to be adopted which most conduces to its utility as a security of the wooden ends, and the efficiency of their caulking, so that there shall be no tendency to set off the buts of the plank.

End the diag als.

For determining the endings of the diagonals, it is further necessary to observe, that the half siding of the stem and stern-post must be drawn in the body plan, together with the depths of their respective rabbets; observing, that with respect to the stem, it is usual to make it of a parallel siding from the head to the lower side of the lower cheek, in order to afford greater support to the bowsprit and knee of the head. From the lower cheek downwards it gradually tapers to the siding of the keel. The stern-post either tapers the whole of its length, or is of a parallel siding from the head to the lower side of the deck-transom, from whence it tapers to the heel. From our preceding remarks, it will be perceived, that in the half-breadth plan the upper diagonals will terminate at the aft part of the rabbet of the stem, and the lower diagonals at the middle of the rabbet. Hence there will be an intermediate point depending on the comparative fulness and sharpness of the bow, at which one diagonal will terminate both at the middle and at the after part of the rabbet; or rather this one diagonal will break in fair with both the middle and after part of the rabbet.

To determine the endings, we proceed thus: In the body plan take the heights of the intersections of the diagonal with the outside of the stem, and with the inside of the rabbet; transfer these heights to the sheer plan, to the after side and to the inside of the rabbet; square down these two spots to the middle line of the half-breadth plan, at which points raise two perpendiculars; along the diagonal in the body plan take the distances from the middle line to where the diagonal intersects the inside of the rabbet and outside of the stem, and set these distances off on the corresponding perpendiculars in the half-breadth plan; thus will be obtained two points, one of which will be the termination of the diagonal according to the form of the body, as before explained.

Or, in the half-breadth plan, with the fore part of the rabbet as a centre, and the after part of the rabbet as a radius, describe a portion of a circle, and let the diagonal at its termination be a tangent to this circle. The after ends of those diagonals which are below the wing-transom terminate in the rabbet of the stern-post, in a similar manner to the fore ends in the rabbet of the stem.

The termination of those diagonals which cross the wing-transom is thus explained. In the body plan, take the distance square to the middle line of the intersection of the diagonal with the margin. Set this distance off in the half-breadth plan, square to the middle line, to intersect the margin. Through the spots thus obtained draw a perpendicular to the middle line, on which perpendicular set off the diagonal distance of the intersection of the diagonal with the margin in the body plan. This gives the termination required.

Water and level lines.

The foregoing remarks will serve to elucidate the plan of terminating water-lines, and also all level lines which are below the wing-transom; excepting that the distances in the latter cases are taken horizontally instead of diagonally.

To run off diagonals in the sheer plan.

To run off the diagonals in the sheer plan: In the body plan, take the perpendicular heights, that is, the heights square to the upper edge of the keel, of the intersection of the diagonal with each of the timbers, and transfer these heights to the corresponding timbers in the sheer plan. Through the points thus obtained draw a curve, which will be the line required.

These lines terminate forward at the aft side of the rabbet of the stem, and aft at the fore side of the rabbet of the post, at the respective heights of their intersection in the body plan, with the sides of the stem and stern-post.

These lines are chiefly required in the sheer plan, when making a disposition of the timbers of the frame; as by their means we show the heights above the keel, of the floor-heads, first futtock-heads, &c.

The horizontal ribbands in the half-breadth plan.

To run off the horizontal ribbands in the half-breadth plan. Having run off the diagonal planes, as just explained, in their true form, it will be necessary to obtain their vertical projections in the half-breadth plan, without imagining them, as before, to revolve into a horizontal position. The diagonals, when projected according to this second method, are called "horizontal ribbands."

Observe the points of intersection of the diagonal in the body plan with each timber. Take the horizontal distance

Laying Off.

of each of these points from the middle line, and transfer it on the corresponding timber in the half-breadth plan. Through the points thus obtained draw a curve which will terminate both forward and abaft on the same lines as the corresponding diagonal, only observing that the distances of the terminations must be taken in the body plan horizontally instead of diagonally.

Water and level lines in the half-breadth plan.

To run off level lines and water lines in the half-breadth plan. Take the horizontal distances, from the middle line of the ship, of the intersection of each timber with the level or water line in the body plan, and set off these distances from the middle line of the half-breadth plan on the corresponding timbers. Through the points thus obtained pass a curve.

The terminations of these lines below the wing-transom have been already explained.

To terminate the after end of a level line above the wing-transom. From the sheer plan square down the intersections of the level line with the aft part of the midship and side counter-timbers, to the middle line of the half-breadth plan. From the foremost of the two points thus obtained, erect a perpendicular to the middle line, and the point where the round-aft of the stern drawn from the aftermost point intersects the perpendicular, will be the termination of the level line.

Without further explanation, this method will serve for the terminations of the top-breadth, top-side, port-sill, and other similar lines. The fore ends of these lines may terminate in the half-breadth of the stem from the middle line.

Buttock and bow lines in the sheer plan.

To run off buttock and bow lines in the sheer plan. In the body and half-breadth plans, buttock and bow lines are straight lines parallel to the middle line. To transfer them from the body to the sheer plan, proceed thus: in the body plan, from the upper edge of the keel, take the heights of their intersections with each timber, and set off these heights on the corresponding timbers in the sheer plan. Through the spots thus obtained pass a curve. Those lines which do not cross the wing-transom may terminate in the sheer plan, at the main-breadth line. Those which cross the wing-transom terminate at the margin as follows. Square up the intersection of the buttock-line with the margin of the wing-transom in the half-breadth plan, to the margin in the sheer plan. The spot thus obtained determines the ending of the buttock-line.

Main-breadth line.

To run off the main-breadth line in the sheer and half-breadth plans. In the body plan this line is a curve passing through each timber, at its widest part. It is transferred to the sheer plan by levelling in its intersection with each timber, to the corresponding timbers; and it is drawn in the half-breadth plan in a manner similar to that before described with respect to water-lines.

We now suppose the draught is complete, and that due precautions have been taken to make the various curves in the three plans perfectly fair. We proceed to explain the method of laying off the more important parts of a ship.

Transferring to the floor.

It will be unnecessary to allude to the manner of transferring the sheer and body plans from the paper on which they are first drawn to a small scale, to the mould-loft, on which they are to be delineated the full size of the ship. The process will be sufficiently obvious to any intelligent person. We will therefore suppose the sheer and body plans transferred to the floor of the mould-loft. This being done, the next operation is to fair the body, by horizontal, vertical, and oblique sections, which is effected by running off in the half-breadth plan, according to our previous description, level lines, buttock-lines, and diagonal lines.

Fairing the body.

Proof timbers.

It should be understood, that, forward and aft, it is necessary to run off a few vertical sections nearer together than the other sections. This is done on account of the sudden curvature in the bow and buttock of a ship. These sections, which are called "proof timbers," may be placed according to discretion; observing, however, that it is essential to have one near the end of the wing-transom.

Laying

Joints o the fram

When the body is perfectly fair on the floor, it becomes necessary to get in all the alternate timbers, or rather joints of the frames, which have been omitted. In the half-breadth plan, bisect the spaces between every joint already laid off, and strike in the new joints, which, like the others, will be square to the middle line. Then in the half-breadth plan take the distances from the middle line, of the intersections of these joints with each of the level lines and diagonals, and transfer these distances to the corresponding level lines and diagonals in the body plan. Thus will be obtained a series of spots through which curves must be drawn to represent the new joints, when all the moulding edges in the body plan will be complete.

Moulds

Supposing the body plan complete, the moulds may be made for the timbers in the square body. With respect to the floors, it is customary for one large mould to contain them all, the fore and after bodies being placed on its opposite sides. This mould, for lightness and convenience, is made of battens; it is connected at the middle line by a pair of hinges, so that when not in use it may be shut together, and thus occupy only one half the space. In trimming a floor, after the spots are obtained from the mould for its curvature, it is sometimes customary to apply the adjacent first futtock-mould through them. With respect to the futtocks, for the sake of illustration, let us imagine one frame of the ship (as starboard, K), instead of consisting of a floor, first futtock, second futtock, third futtock, fourth futtock, and top-timber, to consist simply of two long timbers, each extending from the dead-wood to the top of the side, one on either side of the joint. Were we to make a mould to K in the body plan, it is obvious that it would give the form of both these imaginary long timbers. The only difference in the application of the mould would be, that in moulding the foremost of these timbers the after side of the mould would be uppermost, whereas in moulding the after timber, the fore side of the mould would be uppermost. The reverse would obviously be the case in moulding the larboard timbers. Now, bearing this principle in mind, the moulds are made for the various futtocks, conforming in their length to the respective diagonals which denote the stations of their heads and heels. The scantling of the timbers is marked on the moulds, together with the stations of the ribbands and bevelling spots. As each edge of a mould may be used, one mould answers for two timbers, and their opposites. Where rigid economy is of importance, one mould may serve for several futtocks, in which case the various joints are inked on the surface of the mould, and are bored through the mould to the timber in order to obtain its curvature. This method, however, is not to be generally recommended, because a set of moulds will, with care, convert for several ships in succession.

Bevellir

After the moulds are made, it is customary to take the bevellings of the square body. This subject will, however, be explained generally under the head of cant-timbers, to which we now direct the reader's attention.

Laying the cant timbers.

We have already explained that the plane of a cant-timber is vertical, and inclined at a certain angle to the longitudinal plane of the ship; its projection, therefore, in the half-breadth plan, will be a straight line inclined to the middle line.

In the disposition of the cant-timbers, strength and economy should be considered; hence the propriety of diminishing their curvature and bevelling as much as possible. No particular rule can be laid down for their number and disposition, as these must depend on the form of the bow and buttock of the ship. As a general rule, they should be placed as square as possible to the body, and be equally spaced on the main-breadth and middle lines; their sidings, together with the openings between them, or, in other words, their "room and space," should assimilate as near as may be to the square body. The hawse-pieces should be so situated that they may not be too much wounded by the hawse-holes; and in order that the knight-heads may not be injudiciously weakened by the bowsprit, their heads should be separated from the stem, at least in large ships, by a timber of from six to eight inches siding.

It should be remarked, that in the square body every other joint only is laid off, the intermediate joints being drawn in after the laying off may be said to be complete. But in the cant-bodies every joint is laid off, each joint, as in the square body, serving to mould the adjacent timbers on its fore and after sides. Still, if the opening between the timbers of a cant-frame should be very great, it would be more accurate to strike in the openings on the half-breadth plan, and to lay off each timber independent of the other, that is to say, the after edge of the foremost, and the fore edge of the aftermost timber.

Supposing the disposition of the fore and after cant-bodies completed as in the half-breadth plans (Plates CCCCLI. and CCCCLII.), in which the joints of the cant-frames are marked *c*, we proceed to lay them off in the body plan. This is generally done by one of two methods; either by horizontal ribbands, or by level lines. We must here remind the reader, that the square timbers in the body plan, as A, B, C, &c., 1, 2, 3, &c., are not only projections of the same timbers in the sheer plan, but they are absolutely the real shape of the said timbers, on the supposition that the ship was cut asunder athwartships at those stations. Now, if we conceive a vertical section of the bow to be made, not athwartships, but in the direction of the plane of a cant-timber, as W, Plate CCCCLI. fig. 27, and if we project this section to the body plan, this projection will not be the shape of the cant-timber. But if keeping the plane of the cant-timber W fixed at its vertical intersection with the longitudinal plane, we make it revolve round the said intersection as an axis until it comes athwartships, and if in its new position we project it from the sheer plan into the body plan, then, as in the square body, we not only obtain a projection, but also the true form of the timber, to which a mould may be made for trimming it. We shall now explain the manner of performing this ingenious process, selecting as an example the cant-timber W in the fore body.

To lay off cant-timbers by horizontal ribbands. Observe the intersection of the cant-timber, marked W, with the upper horizontal ribband in the half-breadth plan, Plate CCCCLI.; take the nearest or perpendicular distance of this point from the middle line; set this distance off horizontally from the middle line of the body plan, so as just to intersect the corresponding diagonal. In like manner, obtain similar spots from the remaining horizontal ribbands in the half-breadth plan on all the other diagonals in the body plan, and if through the spots so obtained a curve were drawn, this curve would be the projection, not the true shape, of the cant-timber. Next through all the above-named spots on the diagonals in the body plan, draw horizontal lines. In the half-breadth plan, take the distances along the cant-timber from where it intersects the middle line to its intersection with each of the horizontal ribbands. Transfer these distances to the body plan, by setting them off from the middle line, on each of the corresponding horizontal lines before named. Lastly, through the spots so obtained pass a curve, which curve will be the absolute shape of the cant-timber, which has thus been made to revolve round the point W in the half-breadth plan, from its original position, which was oblique to the middle line, until it came into an athwartship position, or square to the middle line.

We have thus delineated the form of the cant-timber at and below the upper diagonal. To obtain its form at the top-side, proceed thus. In the half-breadth plan, square up the intersection of the cant-timber with the main-breadth line, to the corresponding main-breadth line in the sheer plan. Transfer the height so obtained to the middle line of the body plan, through which point draw a level line. In the half-breadth plan, take the distance in the direction of the cant-timber, from its intersection with the middle line to its intersection with the main-breadth line, and set off the same distance from the middle line of the body plan, along the level line just drawn. Proceed in like manner with respect to the top-breadth, top-side, port-sill, or any other similar lines, and we thus procure a series of spots through which the cant-timber may be continued from below.

Ending the timbers.

To obtain the ending of the timber. Draw in the bearding line or the half thickness of the dead-wood in the half-breadth plan, parallel to the middle line. Square up the intersection of the cant-timber with this bearding line, to the bearding line in the sheer plan. Level in this height to the middle line of the body plan, where a horizontal line must be drawn, on which line set off from the half-breadth plan the distance between the intersection of the cant-timber with the middle line, and its intersection with the bearding line. The spot thus obtained determines the ending of the timber.

Bevelling edges.

Having laid off the moulding edge of W, we proceed to lay off its bevelling edges. Parallel to and on either side of the joint W, draw two lines *ac*, *bd*, to represent the sidings of the adjacent timbers. The side extremities of these lines terminate like the joint at the top-breadth line; their midship extremities are bounded by a small line *ab* drawn at right angles to the joint W at its intersection with the middle line.

In our former description we supposed the joint of the timber to revolve round the point W, until it, the joint, came into an athwartship position. Now, instead of imagining the joint only to be thus circumstanced, let us suppose the whole cant-frame to revolve round the point W; in which case the bevelling edges *ac*, *bd*, will become athwartship lines, and *ab* will become a fore and aft line, and may be regarded as the middle line, or rather a small part of the middle line, of the ship. Hence, in laying off the two bevelling edges *ac*, *bd*, we proceed as was before described for the joint, with this exception, that we take the cant distances along *ac*, *bd*, from the points *a* and *b*, instead of, as before, from the point W, at the middle line.

Bevelling of cant-timbers.

The bevelling edges are delineated, as just explained, in the body plan, in which plan they fall without, coincide with, or fall within, the joint; and these three conditions determine whether the timber has a standing, square, or under bevelling. Therefore, across a board the breadth of which is equal to the siding of the timber, draw a line square to its edges. In the body plan, at the various bevelling spots, as sirmarks, port-sills, heads, &c. take the nearest distances of the joint from the bevelling edges, and set these distances on the right-hand side of the board, either above or below the square line, according as the bevellings are standing or under. Then join the points so obtained, and the intersection of the square line, with the left-hand side of the board. The angles formed by the left-hand side of the board, and the various lines across the board, denote the respective bevellings at the corresponding stations in the body plan, which bevellings will be applied square to the curve of the timber.

Heels of cant-timbers.

For trimming and cutting off the heel two bevellings are necessary. The bevelling against the dead-wood is simply the angle formed in the half-breadth plan by the direction of the timber and a fore and aft line, and is therefore taken by placing the stock of a bevel to the cant of the timber, and the tongue to the bearding line.

To obtain the bevelling for cutting off the heel against the stepping. Square up from the half-breadth plan to the

Laying Off.

sheer plan, the intersection of the joint of the cant-timber with the bearding line. From this point in the sheer plan erect a perpendicular to the keel. Place the stock of the bevel to this perpendicular, and the tongue to the direction of the stepping line, and the required bevelling is obtained.

Laying off by level lines.

To lay off the cant-timbers by level lines. The reader will observe that two processes were necessary in laying off cant-timbers by the horizontal ribbands; for, first, we had to take the square distances of the intersection of the timber with each horizontal ribband from the middle line in the half-breadth plan, and transfer these distances to the corresponding diagonals in the body plan; and, secondly, we had to take the oblique or cant distances of the timber with the same horizontal ribbands in the half-breadth plan, and transfer them to the body plan. But the method of laying off these timbers by level lines is far more simple, only one process being required. Thus, to lay off the joint of W, take the cant distances from the middle line in the half-breadth plan to the intersection of the joint with each level line, and transfer these distances from the middle line of the body plan, along each of the corresponding level lines. A curve through the spots thus obtained gives the true form of the timber.

In considering these two methods of laying off cant-timbers, the reader will remark, that the difference between them consists in this particular, viz. in the first method, or by horizontal ribbands, the heights in the body plan along which the cant distances are set off, are procured from the half-breadth plan; whereas in the second method, or by level lines, these heights are already given in the body plan.

But it may be naturally asked, which is the preferable method? To this we reply, if the student can rely on the fidelity of his labours, let him by all means lay off the cant-bodies by level lines: if, however, he mistrusts the accuracy of his work, let him adopt the plan by horizontal ribbands. The reason of this opinion is, that as the level lines cut the body obliquely, any inaccuracy is more magnified by them than by the diagonals, which cut the body nearly at right angles. With this explanation, we leave the choice of these plans to the discretion of the student.

Bevelling edges.

The bevelling edges are laid off by level lines in the same manner as the joint, except, as in the former method, the cant distances are taken from the points *a* and *b*, instead of from the point W. The bevellings of the timber are taken as explained in the former method.

Cant-timbers in the sheer plan.

To obtain the projection of the cant-timbers in the sheer plan. Square up the intersections of the timber with any of the lines except diagonals, in the half-breadth plan. Diagonals are excepted, because in the half-breadth plan they are not in their natural position, but are supposed to revolve into a horizontal position before they are projected into this plan. Through the spots thus obtained pass a curve, and we obtain the projection required.

This operation is necessary for a variety of purposes. Thus the projection of the fashion-pieces into the sheer plan, shows the boundary of the ends of the transoms. (Plates CCCCLII. and CCCCLIII.) A like projection of the other cant-timbers in the fore and after cant-bodies, shows the arrangement of the heads and heels of the cant-timbers, and their disposition with respect to the bow and after ports.

To lay off the transoms.

To lay off the transoms. As the ends of the transoms are bounded by the fashion-pieces, it becomes necessary to obtain the projection of the fashion-pieces in the sheer and body plans. This is done as previously described with respect to any other cant-timbers. In Plate CCCCLII. the transoms are projected into the half-breadth plan; but as this creates confusion from the multiplicity of lines, it is customary to lay off the transoms by themselves, and to show both sides of the ship. With this view Plate CCCCLIII. is drawn, where fig. 32 represents the plan of the transoms in which the square timbers 29, 31, the buttock-lines 1, 2, 3, 4, 5, the middle line, the bearding of the post, the fashion-pieces, and the wing-transom, are transferred from the half-breadth plan.

Layin

In the sheer plan, where the wing-transom intersects the fore part of the rabbet, a line is drawn at right angles to the keel. This line is called the perpendicular to the transoms. A corresponding line is drawn in the plan of the transoms.

Transoms may generally be divided into four kinds. 1*st*, Those which have a round-up and a sheer: 2*d*, those which have a round-up and no sheer: 3*d*, those which have neither a round-up nor a sheer, their upper and lower sides being level both athwartships and fore and aft; they are called horizontal transoms: and, 4*th*, those which are square to the stern-post, or rather as square to the body as they can be drawn. These are called cant-transoms; their upper and lower sides are planes.

The deck-transom must necessarily have the round-up and sheer of the deck. We have supposed the wing and filling transoms also to have a round-up and sheer to them, although they are sometimes designed, particularly in small ships, without any sheer. It is customary to distinguish the transoms under the deck-transom as No. 1, 2, 3, &c. They are delineated in fig. 31 as horizontal transoms; occasionally, however, they are canted, as AB, Plate CCCCLII. fig. 29.

Laying
horizon
transom

From the nature of horizontal transoms, as previously explained, they will be represented in the sheer and body plans by level lines. (Figs. 31 and 33.) This being done, we have next to make a horizontal section of the ship, at the upper side of each of these transoms, which will of course give the curves to which the moulds are to be made. As the after part of the transoms is terminated either by the fore side of the rabbet, or by the bearding line of the stern-post, in the sheer plan take the distance from the intersection of the upper side of the transom with the fore part of the rabbet, or with the bearding line, to the perpendicular of the transoms. Set this distance off in the plan of the transoms, on each bearding line square from the perpendicular to the transoms, then by joining these two points we obtain the after part of the transom amidships. Again, in the sheer plan, observe the intersection of the upper edge of the transom with each buttock-line. Take the distances of these intersections from the perpendicular to the transoms; transfer the said distances to the plan of the transoms, by setting them off from the perpendicular to the transoms on the corresponding buttock-lines. A curve line passing through these spots will give the form of the upper after-edge of the transom. The accuracy of this curve may be tested thus. In the body plan, take the distances from the middle line of the intersection of the upper side of the horizontal transom with each square timber, transfer these distances from the middle line on each square timber in the plan of the transoms; the spots so obtained ought to correspond with the curve drawn by means of the buttock-lines.

Transo
with a
round-
and she

To lay off a transom which has a round-up and a sheer, it should be understood that the mould given to the workmen for trimming the transom to its round-up is generally a circular arc, applied square to the sheer; and that the mould for trimming it to its round-aft is applied flat upon and bent round its upper surface.

In the sheer plan, at the height of the intersection of the middle of the transom with the fore part of the rabbet of the post, draw a line to the sheer of the transom. Continue this sheer line until it meets the perpendicular to the transoms, at which point draw a line downwards at right angles to the sheer line. Fig. 31.

In the body plan, at the height of the upper side of the transom amidships, draw a level line; draw also a circular arc to the round-down of the transom, square to the sheer, the before-named level line being a tangent to this arc;

at each buttock-line take the distances of the level line from the arc, and set them off in the sheer plan, upon the line drawn square to the sheer of the transom, below the point of intersection of the square and sheer lines. From these points draw lines parallel to the sheer, and where they cut the corresponding buttock-lines, draw a curve which will represent the round-down of the transom below the sheer. To transfer this curve to the body plan, level in its intersection with each buttock-line in the sheer plan to the corresponding buttock-lines in the body plan; through the points thus obtained pass a curve. To delineate the curve in the plan of the transoms to which the mould is to be made, proceed thus. In the sheer plan, observe the points of intersection of the sheer-lines with the buttock-lines; take the distances of these points in the direction of the sheer to the line drawn at right angles with the sheer. Transfer these distances to the plan of the transoms by setting them off on each buttock-line, from the perpendicular to the transoms. Through the points thus obtained pass a curve, which will represent the mould for the upper after-edge of the transom. This curve may be corrected, by means of the square timbers, on the principle before explained with respect to the horizontal transoms. We may here remark, that, strictly speaking, the buttock-lines in fig. 32 should have been expanded, by taking their distances from the middle line in the body plan round the curve of the transom, and transferring them to the plan of the transoms. But as the variation would be very trifling, this operation is unnecessary in practice.

La g off a c -tran- soms

To lay off a cant-transom. In the sheer plan, from the perpendicular to the transoms, take the distances along the upper side of the transom to the intersection of the upper side with each buttock-line and with the bearding line. Set these distances off in the plan of the transoms, on the corresponding buttock and bearding lines, from the perpendicular to the transoms. A curve through these spots will give the form of the transom.

To test the accuracy of this curve, in the sheer plan project the heights of the intersections of the upper sides of the transom with the square timbers and buttock-lines, to the corresponding timbers and buttock-lines in the body plan. A curve passed through the spots thus obtained will represent the transom in the body plan. Next, in the sheer plan, from the perpendicular to the transoms take the cant distances of the intersections of the transom with the square timbers and with the fashion-piece. Set off these distances in the plan of the transoms, from the perpendicular to the transoms, and through the spots draw lines parallel to the said perpendicular In the body plan take the horizontal distances from the middle line, to the intersections of the transoms with each square timber and square fashion-piece. Lastly, in the plan of the transoms set off these distances from the middle line on the lines just drawn, parallel to the perpendicular of the transoms. The spots thus obtained should correspond with the curve previously drawn by means of the buttock-lines.

Bev ngs of t tran- soms

The bevellings of the transoms may be taken in the sheer plan from the buttock-lines, by placing the stock of the bevel in the direction of the upper surface of the transom, and the tongue in the direction of the buttock-line. In this case the stock of the bevel must, when applied, be placed in a fore and aft direction.

If it be thought more desirable to set off the bevellings square to the curve, it will first be necessary to lay off the under sides of the transoms, as before described with respect to their upper sides. This being done, in the plan of the transoms take the shortest distance apart of the upper and lower sides of the transom, at any assigned station. This distance denotes how much the transom is under a square in its depth, and therefore determines the bevelling at the assigned station.

Margin of the wing-transom.

With respect to the wing-transom, it must be observed, that the margin is of a parallel depth all round. The bevelling of the margin conforms to the direction of the fore side of the rabbet of the post. Below the margin the bevellings are taken as before described.

Moulds to the transoms.

Moulds may be made to the after lower edges of the transoms, which moulds are applied on the under surfaces, through the spots obtained from the bevellings.

Laying off the side counter-timber.

We shall next proceed to lay off the side counter-timbers. We have already explained the manner of obtaining the projection of the after edge of the side counter-timber in the sheer and body plans. The fore edge is drawn in the sheer plan by setting off from the after edge the intended size or moulding of the timber. To draw the fore edge in the body plan, square down from the sheer plan the points where it cuts the various level lines, to the corresponding level lines in the half-breadth plan; take the half-breadths of the ship at the points thus obtained, and transfer these half-breadths to the body plan on the corresponding level lines. Hence we obtain the projection of the fore edge of the side counter-timber in the body plan.

Now it is evident that the lines in the sheer plan representing the fore and after edges of the side counter-timber do not give its true form, and that, on account of the tumbling home of the side, a mould made to the above lines would be shorter than the timber itself. Hence it becomes necessary to expand the timber, by making it revolve on a horizontal axis at the heel until it becomes vertical. This process is thus performed. In the body plan draw a straight line, about three fourths of an inch from the upper and lower part of the fore edge of the side counter-timber, as seen in fig. 33, Plate CCCCLIII. This straight line represents the upper side of the mould; its lower end terminates on the level line of the wing-transom at the side; it is marked, in figs. 31 and 33, "base." Having all the level lines marked on this line, imagine it to revolve round its lower end until it comes into a vertical position; mark in the level lines in their new situation, and transfer them to the sheer plan, in which plan the intersections of the edges of the side counter-timber with the original level lines are to be squared up by perpendicular lines to the new level lines. Through the points thus obtained draw curves for the fore and after edges of the side counter-timber in their expanded or vertical position. To these curves the mould must be made.

Next, in the body plan, take the distances along the various level lines, from the straight line representing the mould, to the fore and after edges of the timber. In the sheer plan let the distances just taken from the body plan be marked upon the fore and after edges of the mould at the new or expanded level lines. When the mould is applied on the timber, these distances or spilings are set off in the direction of the tumbling home. After the outside of the timber is completed, the inside may conform to the scantling of the top-side.

We may observe, that instead of the spilings being marked on the mould, brackets are sometimes nailed on the mould, corresponding to the spilings. These brackets are shown in fig. 31, marked *b*. In this case, when the outside of the side counter-timber is completed, the under edge of each bracket exactly conforms to the timber. For the sake of illustration, brackets are also shown in fig. 29.

Bevellings.

To take the bevellings of the side-counter timber from the half-breadth plan, place the stock of the bevel to a fore and aft line, and the tongue to the horizontal round-aft of the various level lines. In applying these bevellings, the stock is placed on the mould to the level lines, and the tongue is placed in the direction of the tumbling home.

We have thus described some of the principal operations in laying off. We have endeavoured rather to illustrate the general principles than the details of the subject; and

Practical Building.

although in this short treatise many things are necessarily omitted which are of importance, as illustrative examples of the art of laying off, it will be found to embrace all those points which are likely to occur in the ship-building of the present day, or at least render them comparatively easy.

Practical Building.

Ship-building.

We now come to the consideration of the branch of our subject to which the term "ship-building" may be correctly applied; that is, the mechanical construction of the fabric of a ship. We have already, in the preliminary remarks to the "Laying Off," described generally the relative position of the principal timbers which compose the frame-work of the hull, and that are necessary to give the contour of the body. Technically speaking, it is usual only to apply the term timbers to the frame-timbers of a ship. We shall, however, for the sake of perspicuity and brevity of description, adopt the term as one of more general application, and use it to designate the larger pieces of wood-work which enter into the construction of the hull. Previously to any detail, we shall mention severally the various internal timbers used as supports and ties to the frame, and the combinations of external and internal plank by which it is covered. This is necessary in order to render the subsequent descriptions intelligible to those unacquainted with the technical names used in ship-building. We must also refer our readers to the plates which are intended to illustrate this part of our article, for much information that may be more easily obtained from them than from description.

Definitions.

The apron is fayed (or fitted) to the after side of the stem, and is intended to give shift to its scarphs; the lower end scarphs to the dead-wood. The keelson is an internal longitudinal range of timbers, situated immediately over the keel, and fayed to the inside of the throats of the floors, its use being to give shift to the scarphs of the keel, and to secure the frames down to the dead-wood. The foremost end of the keelson scarphs to the stemson, which is intended to give shift to the "boxing scarph," or connexion between the stem and keel. The after end of the keelson formerly scarphed to the sternson, a timber which, in a similar manner aft, strengthens the connexion between the keel and stern-post. The keelson is now generally rounded off short of the heel of the sternson, and latterly the boxing scarph of the stem has been discontinued. The additional keelsons, sometimes also called sister-keelsons, are timbers brought on the inside of the frame on each side of the keelson, to receive and to diffuse the weight of the main-mast. Timbers which cross the stemson or keelson forward, for the purpose of connecting the two sides of the ship, are called hooks. Those which are placed to receive the ends of the decks are called deck-hooks. Timbers which for a similar purpose cross the sternson or keelson aft, are called crutches. These hooks and crutches are frequently combinations of timber, or of timber and iron. They are then formed of two half hooks called ekeings, and the middle or connecting piece. Timbers which are fayed to the inside of the frame, or upon the inside plank, solely for the purpose of supporting the frame, are called riders. Timbers which in a square stern fay to the fronts of the transoms, and run forward to strengthen the connexion between the stern and the ship's side, are called sleepers. The two sides of the ship are prevented from collapsing by transverse timbers called beams, which are generally connected at their ends to the ship's side by knees either of wood or iron. The beams are spaced, first with reference to the mast-holes, to the hatchways, ladderways, or passages from deck to deck, and other arrangements connected with the economy of the ship, and then in reference to the ports, that they may afford support to the artillery.

Practical Building.

Those beams which do not extend from one side of the ship to the other are called half-beams; they are placed in intervals between the beams that would otherwise be too devoid of support for the plank of the deck, which is laid on the upper surface of the beams, and called the flat of the deck. Timbers worked round the interior of the ship for the purpose of receiving the beams of the several decks, are called shelves to these decks; and those timbers which are worked upon the ends of the beams, and also round the interior of the ship, are called water-ways; thus, gun-deck shelf, gun-deck water-way, or upper deck shelf, upper deck water-way. Chocks, internally, are timbers brought under the ends of the beams, or under the shelf that is immediately beneath the beams, to support them, and to receive the bolts of the knees which connect their ends with the ship's side. A chock is a name applied very generally to any piece of timber filling an interval, or supplying a deficiency in any of the combinations, either of timber, or of timber and iron. Bits are timbers projecting through the decks, either vertically or slightly inclined, and are used for facilitating the management of the ropes for the rigging. The riding-bits are for securing the cable when the ship is riding at anchor. Standards, generally, now, are timbers used for supports, as to the bits. On the old system of building, standards were sometimes placed where they could only act as ties, as the standard to the stern. There were also standard-knees on the decks, both to support and tie the ship's sides.

The plank, both external and internal, is of various thicknesses: a thick strake, or a combination of several thick strakes, being worked wherever it has been supposed that the frame required particular support; as internally, over the heads and heels of the timbers; both externally and internally between the ranges of ports; and internally, to support the connexion of the beams with the side.

Of the internal planking, the lowest strake or combination of strakes in the hold is called the limber-strake. A limber is a passage for water, of which there is one throughout the length of the ship on each side of the keelson, in order that any leakage may find its way to the pumps; and it is from this that the limber-strake takes its name. A strake of planking is a range of planks abutting against each other, and extending, excepting in particular cases to be afterwards mentioned, the whole length of the ship.

The whole of the plank in the hold is called ceiling. Those strakes which come over the heads and heels of the timbers are worked thicker than the general thickness of the ceiling, and are distinguished as the thick strakes over the several heads. The strakes under the ends of the beams of the different decks, and down to the ports of the deck below, if there be any ports, are called the clamps of the decks to the beams of which they are supports; as the gun-deck clamps, middle-deck clamps. The strakes which work up to the cills of the ports of the several decks are called the spirketing of those decks, as gun-deck spirketing, upper-deck spirketing. The upper strakes of planks, or assemblages of external planks, are called the sheer strakes. The strakes between the several ranges of ports, beginning from under the upper-deck ports of a three-decked ship, are called the channel-wale, the middle-wale, and the main-wale. The strake immediately above the main-wale is called the black strake. The strakes below the main-wale diminish from the thickness of the main-wale to the thickness of the plank of the bottom, and are therefore called the diminishing strakes. The lowest strake of the plank of the bottom, that of which the edge is in the rabbet of the keel, is called the garboard. In merchant-ships the rabbet is generally worked out of the middle of the side of the keel, and not, as in ships of war, at the upper part of the side. Several methods of working this garboard, and the lower strakes of the bottom, have been lately adopted, both in the royal and in the mercantile shipping. One of these plans, see fig. 37, Plate CCCCLIV., called "Lang's safety keel," from the inventor, Mr Lang, the master shipwright of Woolwich yard, has, we believe, been very extensively applied to the keels and garboards of steam-boats; and several of Her Majesty's ships have been built with their garboards so worked. A represents the keelson, B the floor-timber, C the keel, D the outer keel, E the false keel, F, F solid pieces continued fore and aft the vessel, as substitutes for the chocks on the floors and the planking of the bottom.

The pieces of timber, either secured or placed to receive the heels of the several masts, are called steps, as the main, fore, or mizen step. The heel of the bowsprit is also, in small ships, sometimes on a step. In general, the bowsprit steps on a frame-work, called the bowsprit partners. The frame-work of timber which is formed round the mast-holes in each deck is called mast-partners. Partners, generally, are the principal timbers in a framing formed for the support of any thing passing through a deck, as the masts and capstans. Carlings are pieces of timber forming a part of the framing for a deck, lying in a fore and aft direction, and from beam to beam, to receive the half beams, to aid in supporting the deck, and for various other purposes. Ledges are pieces also forming a part of the framing of a deck, generally smaller than carlings, and which are placed athwartships in the same direction as the beams. Coamings are pieces of timber generally faying on carlings, and raised higher than the flat of the deck, forming the fore and aft boundaries to openings in it, as hatch or ladder ways. Head-ledges in the same manner form the athwartship boundaries to these several openings.

The knee of the head, which has been already incidentally noticed in the laying off, is a prolongation of the fore part of the ship, principally of use as a security for the bowsprit, which is firmly lashed to it by portions of the rigging, called the gammoning and the bob stays. The cheeks are knees fayed on each side of the knee of the head, and also against the bows, in the direction of the sheer, in order to afford support to the knee of the head.

We do not profess that this is a perfect list of the components of the hull of a ship. We have merely enumerated some of the more important pieces, or combinations, of timber, the names of which may occur again in our further remarks. It would be impossible, in an article so limited in extent as the present, to enter much into the detail of practical building. We shall content ourselves with endeavouring to illustrate some few general principles, which may guide the practical builder in his arrangements.

There are several very voluminous works explanatory of the detail of practical ship-building. By far the most perfect information on the practice, as it exists in Her Majesty's yards, will be found in the very excellent plates to Fincham's Outline of Ship-Building. We believe the most modern work on the construction of the mercantile navy is Hedderwick's Treatise on Naval Architecture, which contains very minute details of the practical building in the merchants' yards.

Dis rbing forc

We shall now consider the most important disturbing forces which are in action, either to injure or to destroy the several combinations of the hull of a ship. Some of these forces are inherent to the form of the body, while others are only brought into action when the body is in motion. In the theoretical portion of this article it has been explained, that when the ship is at rest on still water, the total weight of the vessel is equal to the upward pressure of the water; but it does not necessarily follow, that the weight of every portion of the vessel shall be equal to the upward pressure of that portion of water which is immediately beneath it. On the contrary, the shape of the body is such, that these weights and pressures are very unequal. We will suppose the vessel to be divided by transverse vertical sections into a number of laminæ of equal thickness, which will all be perpendicular to the vertical longitudinal section. It is evident that the after laminæ comprised in the overhanging stern above water, and the fore laminæ comprised in all the projecting head, also above water, cannot be supported by any upward pressure from the fluid, but their weight must be wholly sustained by their connexion with the supported part of the ship. The laminæ towards each extremity immediately contiguous to these can evidently derive a very small portion of their support from the water; but as their stations in both the fore and the after bodies approach towards the middle of the ship's length, a greater proportionate bulk is immersed, and the upward pressure of the water is increased; so that at some certain station from the middle of the length in each body, the upward pressure will equal the weight of the superincumbent lamina, and all the laminæ comprising that portion of the body between these two stations will be subjected to an excess of pressure above their weight, tending to force them upwards, which upward pressure will be the greatest at the lamina having the greatest transverse area of section.

Now, as we know that the total pressure upwards is equal to the total weight of the vessel, this excess of upward pressure, to which the midship part of the length of the body is subjected, must be just equal to the excess of weight over the upward pressure in the parts of the vessel before and abaft those laminæ at which we have represented the pressure and weight to be in equilibrio.

A ship floating at rest may be considered as a beam loaded at each extremity with a weight, and supported at two points in its length, which are at some distance on each side of its centre, while the part between its points of support is subjected to a force acting upwards equal to the sum of these two weights. A beam thus acted upon would have a tendency to assume a curved shape; and it would gradually assume such a form, as the effect of the weights and forces overcame the rigidity of its particles. This is precisely the effect of the action on the ship; and the upward curvature, when it does ensue, is what is technically called "hogging." As long as the fastenings remain unaffected from the continued operation of the disturbing forces, and the abutments of the several timbers and plank composing the fabric also maintain their close contact, this curvature will not take place; but when these become partially deranged, the upward pressure, and the downward gravitation of the several portions of the body, can no longer be considered as tendencies only to deterioration of the fabric, but as active agents in the work of destruction.

Hogging.

Sagging.

It does not necessarily follow, from all that has been said, that the hogging will give a regular curvature to the form: on the contrary, the various actions of the weight and pressure will produce varied effects. Thus, before the introduction of the additional keelsons, the body frequently "sagged," the contrary or opposite curvature to hogging, under the weight of the main-mast.

A corresponding action to that described as hogging, takes place in relation to the breadth of the vessel, especially on account of the weight of the ordnance; so that the central portion of the body is subjected to an upward pressure forcing it above the water, and the outer portions are strongly acted upon by their unopposed gravity immersing them beneath it. The effects of this action will be modified by the form of the vessel; longitudinally it produces the upward curvature that we have described, and transversely it either tends to a separation of the sides both above and below throughout their extent, or, if the "tumbling home" be great, a separation at the main breadth and below it, and a collapsing of the sides above it.

Horizontal pressure of the water.

Another force tending to alter the form of the ship when she is at rest, arises from the horizontal pressure of the fluid on the surface below the load water-section, which tends to reduce the dimensions below that plane, and therefore to add to the hogging.

Though these are the disturbing forces when the ship is at rest, their action is not confined to that state; they are also in operation when she is in motion. Other injurious effects are produced by, and belong only to, a state of motion.

Pitching and rolling.

If the surface of the sea be very uneven, so that the ship's passage may be over its undulations, her support becomes variable, and the opposing forces of upward pressure and gravitation will have a tendency to produce a corresponding undulation in the body.

Force of the waves.

When the ship is on a wind, the lee side is subjected to a series of shocks from the waves, the violence of which may be easily imagined, from the effect they sometimes produce in destroying the bulwarks, tearing away the channels, and washing away the boats, &c. The lee side is also subjected to an excess of hydrostatic pressure over that upon the weather side, resulting from the accumulation of the waves as they rise against the obstruction offered by it to their free passage. These forces tend in part to produce lateral curvature. Also in this inclined position the forces which, when she is upright, tend to produce hogging, now partly contribute to produce lateral curvature. By experiments made on Her Majesty's ship Genoa, in the year 1823, by Mr Moorsom, formerly a member of the late School of Naval Architecture, he ascertained that this lateral curvature amounted to one inch and a half on each tack, making an alteration of form to the extent of three inches, from being on one tack to being on the other.

Tension of the rigging.

The strain from the tension of the rigging on the weather side when the ship is much inclined, is so great as frequently to cause working in the top-sides, and sometimes even to break the timbers on which the channels are placed.

Taking the ground.

Ships also, especially those designed for the service of commerce, are liable, either from intention or from accident, to take the ground. This contingency must be provided against, as has been already mentioned, in the laying off.

These are the principal disturbing forces to which a ship is subjected. It must be remembered that they are in almost constant activity to destroy the connexion between the several parts of the fabric; and that whatever "working" may be produced by their operation, tends most materially to increase their effect; because the disruption of the close connexion between the several parts admits an increased momentum in their action on each other, and the destruction proceeds with an accelerated progression; while the admission of damp, and the unavoidable accumulation of dirt, soon generate fermentation and decay. To make a ship strong, is at the same time to make her durable, both in reference to the wear and tear of service, and the decay of materials. But there is one very important consideration which should be remembered in the construction of all fabrics with so perishable a material as timber; it is, that all strength beyond that which is necessary to insure durability to the fabric equal to the durability of the material, is a waste both of labour and material; or, in other words, if a ship, built at an expense of L.40,000, will last twelve years, it would be false economy to expend L.60,000 in building one to last fifteen years.

If, by any means, the durability of wood should be much increased, it would be also necessary to increase the strength of the ships built of it, that the durability of the construction might equal the durability of the material.

Hogging as it affects the structure.

We see from this outline, that the forces which cause the hogging, which are the most important disturbing influences, commence their action at the moment of launching of the ship, and are thenceforward in constant operation. This curvature can only take place by the compression of the materials composing the lower parts of the body, and by the elongation of those composing the upper parts. We therefore have to determine the divisional line separating these two actions, and to form the combinations above and below this line, to offer opposition in accordance to the different directions of the strains to which they will be subjected. Dupin, in his able paper on Seppings' Diagonal System, fixes this line of inaction at about the surface of the water. According to the accepted theory of the strength of bodies, it would be situated lower than this in large ships; but the horizontal pressure of the water, already mentioned, makes the case of a body supported on a fluid an exception, and the station assumed by Dupin must approximate nearly to the correct position.

The portion of the ship about the surface of the water must therefore be considered in the light of a foundation to the fabric, and should be strengthened, not only to resist the inequalities of the strains to which it will be itself subjected, especially when the ship is in motion, but also to constitute it a firm basis, from which to extend supports to those portions of the hull both above and below it, that will be subjected to yet greater disturbing forces than itself.

In order to resist the tendency to hogging, the object of the ship-builder should be to form an incompressible mass below this line of inaction, and to render the body rigid and inextensible above it; hence the immense advantage gained from Sir Robert Seppings' plan of filling in the openings in the lower part of the frame, and especially of the plan which he introduced of filling them with cement that so far exceeds any timber in hardness. The various abutments of this part of the body should be as closely fayed as possible. In the dead-wood the buts of the shifts should all be cut off square to the joints, and the abutting surfaces multiplied by the interposition of dowels in these joints, the abutments formed by which are certain, and hence the advantage of dowelling the kelson, rather than scoring it over the floors. In this part of the body the length of the scarphs is not of so much importance as the close abutment of the lips, to insure which the scarphs should be keyed. The keel scarphs are an exception to these remarks, as they require additional and different security, from being external openings.

The tendency of the hogging will be to alter the angles formed by the post and the stem with the keel; therefore it is necessary to strengthen the connexions of these timbers by every means which will oppose this tendency, as elongating all the shifts, hooking all the scarphs, and judiciously distributing and supporting all the fastenings. Hence the advantage of a dead-wood knee, as adding most considerably to the strength of the connexion abaft, and enabling a more regular and advantageous application of the bolts to be made. This object of strengthening the connexion of the post and stem with the keel, is therefore the consideration to be attended to in shifting the after shifts of the after dead-wood and the sternson, and in shifting the fore dead-wood with the stem, apron, and stemson, and also in disposing the fastenings which pass through these timbers. The old plan of running the keelson aft to scarph with the sternson added materially to the tie. Another important support to the stern in line-of-battle ships, is a carling brought up under several of the after beams of the gun-deck, and secured to them; its after end being connected to the head of the sternson by side-plate knees.

There is more necessity for attention to the support of the stern than to that of the bows, because, when a ship is under weigh, the after part beneath the water, as it has been already explained, is deprived of much of the pressure to which it was subjected when at anchor, and therefore the effect of the gravitation is less opposed. Hence also the "cambering," or curving outwards, of the stern-post. The cambering of the post might, however, be greatly prevented, by a tie-bolt connecting it with several of the after beams of the lowest deck, among which the strain would be diffused by the carlings between them. This might now be done even in line-of-battle ships, as they carry their orlop-beams right aft.

Since compression is the action to which the lower part of the body is subjected, we see the evident inutility of sacrificing economy in order to obtain length of shift for the plank of the bottom, or, indeed, of making any great sacrifice of plank for this purpose below the surface of the water, excepting for the foremost and aftermost shifts, at the bluff of the bow, and under the buttock.

The deck below the water, that is, the orlop, in ships of the line, and the lower deck in frigates, though near the neutral line, are below it; and therefore the action to which they are subjected is compression, to resist which the ranges of carlings should be maintained from one extremity of the vessel to the other, and all their abutments should fit as closely as they can be got in place.

We have mentioned the keel scarphs as an exception to our general remarks. They are usually in England vertical scarphs, with coaks raised in the lip-ends of the scarphs, to fit into mortices sunk for their reception in their but-ends. These coaks serve as a stop to the caulking, and, in connexion with the scarph-bolts, are well devised, in the event of the curvature of the keel, to enable the scarph to partake of it, and to prevent leakage. In France, and generally in the foreign yards, the scarphs of the keel are horizontal. Very lately the horizontal scarphs have been adopted in the English service. We consider the vertical scarph much to be preferred, for the reasons above stated.

In those parts of the ship situated above the line of inaction, every means should be taken to multiply longitudinal ties. Since, in order to resist compression in the lower parts of the body, the openings are filled in, and form a solid mass; to produce the opposite effect, that is, to enable the frame to resist extension, it should be chain-bolted together towards the upper parts of the body, wherever the continuous range of bolts can be placed not to interfere with the in and out fastenings; as opposite the openings between the shelf and water-way of the several decks just above the scuppers. This plan has been pursued in several of the modern ships. The shifts of the different walcs, spirketings, and clamps, should be long, the regular shift of the buts most carefully maintained, and the buts of the inside assemblages made to give shift to the buts of those outside. Sir Robert Seppings' plan of supporting the fastenings, and compensating for the weakness of the buts in some of the principal assemblages of plank, by dowels into the timbers in the strakes immediately above and below the buts, is of great utility. Also the plan of connecting several strakes together by tie-bolts placed opposite the openings between the timbers in the frame, where they could not interfere with any fastening, was admirably adapted to diffuse strength, and to prevent longitudinal working of the planks, or the sliding of one edge past another, from any partial weakness. These might advantageously be much more extensively applied than was contemplated in the instructions issued by Sir Robert; indeed, to all the internal assemblages of plank in which they can be driven.

The ank-
ing.

Plank is either worked in parallel strakes, when it is called "straight-edged," or in combinations of two strakes, so that every alternate seam is parallel. There are two methods of working these combinations, one of which is called "anchor-stock," and the other "top and but." The difference in their appearance will be best seen by a reference to Plate CCCCLVIII., fig. 43. The difference in the intention is, that in the method of working two strakes anchor-stock, the but of one strake always occurs opposite to the widest part of the other strake, and there is consequently the least possible sudden interruption of longitudinal fibre arising from the abutment; therefore this disposition of plank is used where strength is especially desirable. In top and but strakes the intention is, by having a wide end and a narrow end in each plank, to approximate to the growth of the tree, and to diminish the difficulty of procuring the plank.

The shift of plank is the manner of arranging the buts of the several strakes. In the ships of the royal navy the buts recur with intervals of three whole strakes between. In merchant-ships there are often not more than two whole strakes between the recurrence of the buts. The regularity of the shift of plank is far more carefully maintained in English building-yards than in those abroad.

The fastening of the plank is either "single," by which is meant one fastening in each strake through each timber of the frame which it crosses; "double," or two fastenings in each timber; and "double and single," meaning alternations of the double fastening in one timber with the single fastening in the next.

This fastening consists generally either of nails or treenails, excepting at the buts, which are secured by bolts. Several other bolts are driven in each shift of plank as additional security. These additional fastenings are far more plentifully diffused in the royal yards than in those of private builders. Whatever system of securing the plank may be determined upon, great care should be taken to guard against a repetition of fastening, which will otherwise occur from the various bolts that will come through the bottom as securities to the riders, shelves, water-ways, knees, and bolts connected with the service of the guns. These bolts should evidently, for economy, and also for the sake of avoiding unnecessarily wounding the timbers, supply the place of the regular fastenings of the plank.

Before copper sheathing was introduced, iron was used for fastening. Since then, either bolt-nails cast of a mixture of zinc, copper, and grain tin, technically called "metal," or pure copper bolts, are used in addition to the treenails. Experiments are now being made in Holland to protect iron bolts, used for fastening the plank on ships' bottoms, from the galvanic action induced by the copper. The bolts are punched within the wood, and covered with a cement made of equal parts of lignum vitæ saw-dust, smiths' ashes, and "minium." In France also several ships' bottoms have lately been iron-fastened, with Roman cement over the bolts; they were then felted and sheathed, the sheathing being secured with copper nails, and the bottom afterwards coppered. This inquiry as to the possibility of applying iron for the fastening of ships in connexion with the copper sheathing, is of great importance, as, independently of the difference in the expense of the two metals, the difference in their tenacity is as 995 to 546, or copper is only about $\frac{11}{20}$ths of the strength of iron, or little more than one half.

The plank in the royal yards is not usually permanently fastened for some time after it is trimmed and brought on to the bottom of a ship, but is temporarily secured by Blake's screws, and allowed to season and shrink. About one strake in eight or ten is left out for the purpose of making good the shrinkage and refaying the strakes. Without this precaution there would be such an alteration of edge as would throw the holes made for the temporary securities out of the ranges of the strakes; but this precaution being taken, it is very seldom that the alteration of edge is such as to require new holes, especially as the iron screw eye-bolts used for this temporary fastening are of much smaller diameter than the permanent treenail fastening, and therefore the holes for the screws will make good holes through the plank for the treenails.

Temporary fastening.

This method of securing the planks in a temporary manner is of immense advantage in enabling them to be brought into close contact with the timbers, in the saving of bolt-fastenings, and in causing a good and regular seam to be given for the caulking.

The circumference of the bottom being much larger at the midship part than towards the extremities, that is, at the bow and buttock, the lines for the strakes of plank must

Sny. **Hang.**

close, and the strakes taper as they recede from midships. They also acquire an upward curve, called "sny," which renders it difficult to work the plank. When the sny becomes too great, a strake is ended short of the rest, and this is termed a "stealer," as it diminishes the sny for the succeeding strakes. Under the buttock it is often necessary to work some of the after plank wider at the after end, which has the same effect of diminishing the sny of the following strakes. "Hang" is the exact reverse of "sny." It mostly occurs in working plank on the inner surface of the timbers, and outside above the main breadth.

The various plans for fastening the plank and for securing the buts will be most easily understood by a reference to Plate CCCCLVIII. fig. 43.

Caulking. When the plank is worked and fastened, the seams, or the intervals between the edges of the strakes, are filled with oakum, or "caulked," with such care and force, that the oakum, while undisturbed, is almost as hard as the plank itself. If the openings between the strakes were of parallel width throughout the thickness of the plank, it would be impossible to make the caulking sufficiently compact to resist the water. The inner part of the edges of contiguous strakes should be in contact throughout their length, and from this contact the edges should gradually recede from each other to the outer surface of the plank, so that at a thickness of about ten inches they would be about $\frac{10}{16}$ths of an inch apart; that is, about $\frac{1}{16}$th of an inch seam for every inch in thickness of plank. The practice in the royal yards is to allow a double thread for every inch in thickness of plank, and an additional double thread for every five inches; besides which, one, or sometimes two, threads of spun-yarn are driven in as a bottom to the oakum. In the merchant-yards on the Thames, and where the larger merchant-ships are built, the caulking is nearly the same as in the government establishments. But in the smaller ships built at the outports, the oakum is seldom "bottomed" home to the inner edge of the seam, the consequence of which is, that the uncovered edges of the planks decay, and the second caulking drives the oakum through, after which the seams cannot long be kept tight.

It is the generally received opinion, that however the French may have excelled us in designing the body of a ship, our practical building has always been incomparably superior to theirs. In so far as the skill of the workman is involved in this opinion, we believe it to be strictly correct.

The workmanship of English mechanics is probably unrivalled, certainly not surpassed by that of any other mechanics in the world, either in solidity or in neatness of execution; but we cannot in justice urge the claim of superiority further.

However weak the French prizes taken during the last century may have been from defective workmanship, the materials were in several instances much more judiciously combined for the purpose of obtaining strength than in the contemporary ships in our service. Indeed it was not until after Sir Robert Seppings became surveyor of the navy, that the absurdity of having the sheer of the ship and the sheer of the ports different from each other, was discontinued. The effect of this difference in their sheer was, that the assemblages of thick strakes brought round the sides for the purpose of strengthening them, were actually cut off from being crossed by the sheer of the ports. In the majority of the French and Spanish ships taken at so early a period as the middle of the last century, the sheer of the ports was the same as the sheer of the ship, consequently the whole strength of the thick strakes was preserved. The shelf was also originally copied from the French; and though they have now discontinued it, it was at the period of its introduction an important improvement. Also we have only followed them in the adoption of iron knees for the security of our beam-ends. In making these animadversions, we speak wholly of the past. For many years British ships have been unequalled for strength, as well as for perfection, of workmanship.

It has become almost a fashion to decry the improvements introduced by Sir Robert Seppings. It would be well, perhaps, to remember the complaints continually made, of the weakness of the ships before he became surveyor of the navy, and to contrast the fleets of England at that time with the fleets which he left in the service when he relinquished the surveyorship. There is no doubt that many of his plans were imperfect, and are susceptible of great improvement. No change ever yet was made, or ever will be made, that was not and will not be susceptible of yet further improvement.

Decks. We have already mentioned the decks which are situated below the line of non-action; those above it must all be considered as most valuable longitudinal ties. Their sheer has been most properly much diminished within these last twenty years. It is evident, that for rigidity, decks without any sheer would be advantageous. The sheer was probably given them to facilitate the run of water to the scuppers, and may perhaps be desirable for this purpose; but certainly, as strength is lost by their curvature, the sheer of the decks should be as little as possible. It may be objected, that perfectly straight decks would be injurious, or at least very unsightly, in the event of hogging taking place. The objection is not valid; strength must not be sacrificed in order to prepare for the occurrence of a contingency which we are endeavouring to prevent, and which evidently may be prevented for a great length of time, since the various improvements introduced during the last five-and-twenty years have certainly almost wholly prevented the weakness in ships, which was before such a source of constant complaints.

Fastenin decks. The only consideration, in fastening decks, is to preserve their contact with the beams, and to withstand the action of caulking: more than enough to effect this object is useless, and therefore the numerous bolts introduced with the system of diagonal decks were unnecessary. It may probably be proper to observe, that the harder the material used for the flat of decks, the greater should the quantity of fastening be, as there will be less yielding of the edge to the caulking; and although it is usual to allow more seam for caulking planks of a hard than of a soft material, the caulking will bring far more strain on the fastenings of the harder than on those of the softer; besides which, strictly speaking, though it is not practically expedient, seam should depend upon thickness alone. It may not be improper to mention here, that the quantity of fastening must increase with the thickness of the plank, whether of deck or bottom, which is to be secured; for the set of the oakum in caulking will have the greater mechanical effect the thicker the edge.

Diagona deck. The diagonal deck, whatever advantage it might have been presumed to possess in other respects, was certainly a great loss of strength in as far as longitudinal tie was involved, and, we consider, has been most judiciously discontinued. The rapid deterioration arising from the wear occurring across the fibre of the wood, with the additional inconvenience, that the partial wear along the working passage of the deck, by crossing every strake, involves the shifting the whole flat, is alone a strong argument against any alteration in the system of laying the strakes of deck fore and aft. Mackonochie proposed to lay decks in three layers, one diagonally from starboard to larboard, another diagonally from larboard to starboard, and an upper layer fore and aft. He also proposed a somewhat similar system for the outside plank, from the garboard to the wales. Merchant-vessels have been built in America, and boats and steam-vessels in this country, on this system of layers of planks laid diagonally.

Sir Robert Seppings was apparently aware of the important tie which a deck is to a ship, as he retained some of the midship-binding strakes, and introduced dowels to render their connexion with the beams and with the extremities of the vessel more perfect and more unyielding than could be effected by the old plan of scoring down, with its attendant evils from the shrinkage of the materials and neglect of workmanship.

The aftermost and the foremost beams of each deck might be advantageously made to afford support to the projecting bows, and especially to the raking sterns of the modern ships, by connecting the bow and stern timbers to them at each deck by long tie-bolts passing through several beams, clenched on the aft side of the aftermost forward, and on the fore side of the foremost of them aft. These beams should have several ranges of carlings let down between them, to diffuse the strain. This would be far preferable to forelocking the bolt on the fore side of each beam; first, because, generally speaking, the strain would only fall upon one beam, that which was most closely forelocked; and, secondly, because by experiment we find that the size of the bolt being the same, the forelock would give way, or the bolt break at the forelock-holes, under about one half the strain which the clench would withstand.

Several Dutch ships have been built with a round-up to the decks in the direction of the length; the keels of the same vessels were built to sag or curve downwards towards the midships of the length, and the fore and after extremities were so constructed that the longitudinal vertical section should form an elongated ellipse. Only steam-boats have, we believe, ever been built on this plan.

Bea

The beams which support the deck have a curve upwards, in the direction of their length, to the middle of the ship, called the "round-up." This is for the purpose of strength, and for the convenience of the run of water to the scuppers. Beams are single piece, two, three, or four piece (Plate CCCCLIV., figs. 39, 40, 41, 42), according to the number of pieces of timber which are combined to form them. The several pieces are scarphed together, and coaked and bolted, the scarphs being always vertical. Hooked scarphs, with keys of hard wood or iron driven in, to bring the buts in close contact, have been lately introduced with much advantage in great additional neatness of appearance, great reduction of weight, and consequently of materials and expense, by Mr Edye, the master-shipwright of Pembroke yard, fig. 38.

Iron pli- ed t hip- buil g.

It is rather surprising, that in the very general application of iron for ship-building, the wooden beams which occupy so much space between deck and deck, and so materially contribute to the height of the vessel above the water, have not either been superseded by beams of iron, or at least by wood beams of much less moulding, to which the necessary rigidity might be given by iron plates at their sides. An objection to beams wholly of iron would arise from the great expansion and contraction of that metal under variations in its temperature.

The beams of ships are supported at each end, and the strain to which they are subjected is a downward pressure; consequently the upper part of the beam must compress, and the lower fibre elongate, before there can be any alteration in the curvature. It is desirable therefore that the fibre of the wood towards the lower part of the beam should not be wounded, and that, whether for the purpose of securing the beam, or of security to the beam, no incision should be made, excepting in the upper, or compressed, ranges of the fibre, which may be cut through, according to Du Hamel's experiments, one half, and according to Professor Barlow's, five eighths, of their depth, without impairing the strength. Nay, if the carling or material to be inserted in the score be of harder texture than that which is removed, the strength is increased.

Connexion of beam-ends to ship's side.

The connexion of the ends of the beams to the sides of the ship has afforded scope for the display of much ingenuity. We have in our plates (CCCCLV. and CCCCLVIII.) given sketches of those plans which have been adopted in the navy of England, and also of several taken from foreign works or observed in foreign yards. There are three things to be considered in the connexion of the beam with the side: that it shall act as a shore to prevent the sides from collapsing; as a tie to prevent their falling apart; and be perfectly rigid, that there may be no working.

That the beam may be an effective shore, nothing more is necessary than that the abutment of the end against the ship's side may be perfect. In order to constitute it a tie between the two sides, it is generally dowelled to the upper surface of the shelf, and the under surface of the water-way is dowelled to it. These dowels connect it therefore with the fastenings of the shelf and water-way, which pass through the side. There is also in the ships of the royal navy a plank called a side-binding strake, scored down over and into the beam-ends, at some distance from the side, and bolted through the side between the beams. The scoring into the beams connects the in and out fastening of this strake with the longitudinal tie of the beam. There are also the various bolts forming that part of the fastening of the beam-ends, whether in the knees or in the chocks, which passes in and out through the ship's side.

It will be very easily conceived, from the short outline which we gave of the disturbing forces acting on a ship, that the strain on the ends of the beams to destroy the rigidity of their connexion with the side must be very great when the ship is under sail either on a wind or before it, that is, either inclined or rolling.

Forces to which they are subjected.

The principal action of these forces is to alter the vertical angles made by the beam and the ship's side; and it will be seen that the action is alternately to decrease and to increase the angles made by the beam and the part of the side below it, or, what is the same thing, alternately to increase and decrease the angles made by the beam and the ship's side above it. Now the first of these actions takes place on the lee side; the gravitation of the weather side, and all connected with it, of the deck and every thing upon it, as well as the upward pressure of the water, all tend to diminish the angle made by the beam and the ship's side below it, and increase the angle made between them above it. The contrary effect is produced on the weather side, the angle above the beam being closed, and that below opened.

Beams considered as levers.

In investigating the nature of the action of these forces, we shall find that in each case the beam may be considered as a lever. The power being supposed to be applied at the opposite end of the beam to that at which the forces under investigation act, the weight being the fastening applied to prevent alteration in the angle formed by the beam and the ship's side, and its action being supposed to take place at the point in which it should be applied to produce the most advantageous effect.

Effect on lee-beam arm.

On weather-beam arm.

The lever is of the first order, that is, with the power and weight on opposite sides of the centre of motion or fulcrum, when its effect on the lee arm is considered; and it is of the second order, that is, with the power and weight on the same side of the fulcrum, when its effect on the weather arm is considered.

The object in securing the beam-ends in each case should be to diminish the effect of the power and increase that of the weight. We lessen the effect of the power by diminishing the distance between the point at which it acts and the fulcrum, and we increase the effect of the weight by increasing the distance between the point at which it acts and the fulcrum. In the lever of the first order, that is, when we are considering the action on the lee arm, this is accomplished by bringing the support of the under side of the beam, the midship side of which support is the fulcrum of the lever, as far from the ship's side as it can be extended consistently with the accommodation of the decks; and by having the weight, that is, the security to keep down the beam-end, as close to the end of the beam, and consequently to the ship's side, as it can be placed.

In the lever of the second order, that is, when we are considering the action on the weather arm, the effect of the power is diminished by increasing the distance between the fulcrum and the weight. The fulcrum, in this case, is the support of the lower side of the extreme end of the beam; the weight is the strength of the knee, or whatever connexion is intended to tie it to the ship's side, and maintain the angle invariable which is formed by them. The effect of this weight is increased by approaching it to the point at which the power is supposed to act. Therefore, in order to resist the action on the weather arm of the beam, the fulcrum, which, as we have said, is the support of the extreme end of the beam, that is, the edge of the clamp or shelf which fays to the timbers, should be most firmly connected to them; and the weight, which is the downward tie, should be extended as far from the side as it may be consistently.

The difference of the action to which the two arms are subjected, points out therefore at once the principle which should guide us in all plans for connecting the beams to the side, and it may not be useless to recapitulate our conclusions.

The action on the lee arm requires the extreme end of the beam to be closely tied down, either to the clamp or the shelf, as the case may be, and which is necessarily presumed to be firmly connected to the ship's side. This action also requires the centre of motion to be extended far from the side, in order to diminish the effect of the power. Therefore, the downward fastening close to the ship's side, and the upward support far removed from it, is that which is necessary in this case.

The action on the weather arm requires an exactly different disposition of the securities. The extreme end of the beam is here the centre of motion, and is the part which ought to be supported; and it is the downward tie which should be as far extended from the side as may be consistently.

It may be urged against these views, first, that if working be presumed to take place in the lee-beam arm, round the midship or outer edge of the shelf, the distance between this fulcrum and the fastenings which keep the beam-end down will cause greater motion in that end, and greater strain on the fastening; and, secondly, that if the weather-beam arm be presumed to work from the side or inner edge of the clamp or shelf, the distance between this point and the fastening intended to keep the beam down, will cause an increased strain on that fastening.

These objections are both true, but they do not embrace the correct view to be taken. The object is how to dispose the fastenings in the best possible manner, in order to prevent working. And this is attained in each case by extending the distance between the weight and the fulcrum.

Shelf and clamp as securities of the beam-end.

In the system of building the ships of the royal navy, introduced by Sir Robert Seppings, the shelf was brought upon the clamp (*m*, Plate CCCCLV.); it is now worked home to the timbers (*i*, *k*, *l*), and its front is therefore less extended from the side. One joint, that between the clamp and shelf, is avoided by this method, but security to the beam-end is lost by it. An arm of the iron knee, which has superseded Sir Robert Seppings' forked knee, is extended under the beam to compensate for this diminution in the width of the shelf; but unless the rigidity of this arm be such that the fulcrum in the case of the lee-beam arm, and the weight in the case of the weather-beam arm, be removed from the ship's side a distance at least equal to the diminution in the extension of the front of the shelf from the ship's side, the object is not attained.

Plate-b

One of the most perfect securities for a beam-end, in point of principle, and combining at the same time simplicity of workmanship, which is another important requisite, especially in all iron work, is the plate-bolt (*a*), frequently adopted for round-house beams, and for the lower decks of frigates. The extreme end of the beam is tied downward by bolts, and supported by the shelf, and the extended downward fastening is by a dog-plate. These securities, and the upward support afforded by the chock to that plate, are, according to the foregoing reasoning, correctly applied, but are insufficient in amount of security for the beams of principal decks, as the downward tie depends wholly on the clench of the dog-plate.

Strap.

Probably a strap passing round the beam, as shown in fig. 44, Plate CCCCLVIII., might be an advantageous and simple modification of the above plan. For easiness of execution, and smallness of expense, it would be better if the strap was merely bent over, and scored into the top part of the beam, and the ends brought down and fastened on the sides of the chock, which would then require to be only of the same siding as the beam. In this case there could be no in and out fastening through the strap; the only in and out bolts would be those through the chock. The fastenings of the strap might be screws, as in the French knees (Plate CCCCLVIII. figs. 45, 46), which we shall describe. The disadvantage attending this sort of strap would be, that to obtain an equal degree of downward security for the weather-beam arm, the chock must be more extended from the ship's side than if the ends of the strap were brought in front of the chock, and took their own in and out fastening.

Advantages of the choc

The extension of the security from the side of the ship by means of a chock, is preferable to gaining the same breadth by bringing a shelf on to the clamp with a chock under it, in so far as extending the support to the beam is involved; because the chock presents "end-grain," in which there is comparatively but little shrinkage, to receive the downward pressure of the weather-beam arm. A well secured and firmly supported clamp is sufficient to resist the downward pressure of the weather-beam arm; and if this clamp be of a sufficient thickness to receive the up and down bolts through the water-ways and beam-end, that is all that is indispensable, and this would be little, if any, addition to the thickness of clamp already usually worked. We therefore doubt much whether the shelf might not be advantageously discontinued, and substituted by a clamp with chocks under the beams, stepping on the projecting edge of the spirketing. We shall speak of the support to this clamp when we consider the short stuff between the ports. Of course this change presupposes a maximum of advantage to be derived from all the other combinations for strengthening the side.

Object a to choc

An objection is urged against chocks, which is, that they occupy space against the ship's side; but they afford security to the beam-ends which cannot be well obtained without them; and it is questionable whether the foundation of the objection is correct, because the continuous breadth of shelf should also be considered, and that effectually prevents a man's standing erect close to the ship's side, while the obstruction from the chocks is only partial, with intervals between.

Rober plate-k

Roberts' plate-knee (*d*, Plate CCCCLV.) is a very strong method of fastening, as a preventive to any alteration of the angle formed by the beam and the side, provided the in and out security of the chock to the side is sufficient to resist the strain that is brought on it. These knee-plates, together with up and down bolts in the beam-ends, fulfil all the requisites for a correct mode of fastening, unless it may be the objection against the chock which we have stated. The great objection which has been urged to their use arises from the fore and aft bolts through the beam, which, it is said, are liable to split the beam-end.

All fore and aft bolts through the beam-end, as they do not pass through the fulcrum round which the beam would work, are nearly equally liable to this objection, whether they occur in the same range of fibre or not, because when motion ensues they must all act to split the beam-end. But we have already said we do not consider this line of argument should be urged. The occurrence of working should not be presupposed in determining securities to prevent it, because such a course would frequently militate against the application of the most advantageously disposed preventives to motion; not however that we are arguing in favour of fore and aft bolts through beam-ends ranking among these; on the contrary, we think they should be avoided.

The foregoing observations embrace the main outline of the principles which should be kept in view in connecting the two sides of the ship by means of the beams.

Ho

The bows, as we have already said, are connected by timbers called hooks. It is important to remember that the hooks above and those below the surface of the water are subjected to an opposite strain. The tendency of the pressure of the water on the bow is to make the sides collapse, and therefore the hooks below the water's surface should not only act as ties to the bow while the ship is grounded, as, for instance, when in dock, but should be formed more especially to resist the pressure of the water when she is afloat. Those hooks which are above the surface of the water act principally as ties, the rake of the bow and the gravitation of its parts tending to separate the two sides of the ship. These observations are of little importance when the hooks are of wood; but when they are formed partly of wood and partly of iron, they materially affect the application of the iron plate. Below water it should evidently be brought as close to the inner surface of the bows as possible, and therefore on the fore side of the hook. It should also be secured to the wooden ekeings, independently of the bolts which secure the hook to the bows. Very slight consideration will suffice to prove, that by these means the utmost advantage is obtained from the materials employed, to resist the pressure, while at the same time they form a sufficient tie to support the sides of the bows when the ship is in dock, before launching, or aground. In made hooks above the water, the iron plate should be on the aft side, as far from the bow, and as straight as may be, that it may be a more effective tie.

We shall now pass to the several systems of strengthening the sides, and of preventing the hogging, which have been successively introduced.

Vertic riders.

In the system of building which was superseded by that termed the diagonal system, the whole of the interior surface of the frame was planked, and a series of internal frames worked upon this planking, agreeing in direction with the timbers of the ship (Plate CCCCLVI. fig. 47). They appear principally to have been intended to support the frame in the event of the ship's grounding, as they could add no longitudinal strength to the fabric. There were about eight "bends" of the "riders" in three-decked ships, and six bends in two-deckers. There were other timbers running up to the top-sides, called breadth, middle, and top riders. These were more closely spaced than the bends in the lower parts of the body, and were placed in a diagonal direction evidently only to avoid the ports. The beams were secured to the side by hanging and lodging knees of wood: they rested on the clamp, there being no shelf. The water-way was merely a thicker strake of deck gouged out, or "chined down," as it is technically called, from the front of the spirketing, to the same thickness as the flat of the deck. This chining down is for the protection of the water-way seam, by keeping it above the run of the water. There were different methods of shifting the bends of riders in the hold, several of which we have introduced in the plate.

An enormous quantity of timber was thus massed together, having the appearance of great strength; but in fact, from its weight, injudicious combination, disposition, and fastening, much of it was, if not injurious, at least useless. The riders in the hold were no doubt originally necessarily introduced when ships were "grounded" for repairs; but that necessity has now ceased to exist. In the earliest drawings representing them there are "pointers," or shores, extending from them at the bilge of one side, to the gun-deck at the opposite side of the middle line, which we shall presently refer to.

The system we have described was partially superseded by single riders in the hold, scarphing to chocks under the orlop-beams, and running down to give shift to the floor-heads. The top-sides were supported by standard knees brought on the deck over the beams; and the beams were secured by Roberts' plate-knees brought on the sides of chocks under the beams.

The idea of diagonal trussing was not novel at the time the system of Sir Robert Seppings was first proposed: It may even be observed in Plate CCCCXLVI. in the vessel of the fifteenth century, under repair. In the plates of a Dutch work of the date of 1697, there are diagonal pointers in an athwartship direction from the floor-heads on one side, to the quarters of the upper-deck beam of a two-decker on the other. Sir Walter Raleigh also mentions this mode of strengthening ships; and the Dutch author, Van Yk, gives the drawing as a representation of the English system of building at the date of the publication of his work. Somewhat similar also were those afterwards proposed by Mr Snodgrass, the surveyor of shipping to the East India Company, though his were to step upon the keelson and extend to the clamps of the lowest gun-deck, and were therefore less judiciously placed to resist the strain in grounding than those represented in the Dutch work. Diagonal trussing between the keelson and the gun-deck beams along the vertical longitudinal section of the ship, had also been proposed, and partial experiments of various diagonal supports or shores made, both abroad and in England; but until the introduction of the diagonal riders and trusses by Sir Robert Seppings, there had been no permanent results from these experiments.

We quote the following description of the system from a paper communicated by the inventor to the Royal Society, and which is printed in the Philosophical Transactions for 1814.

Diagonal frame.

"An accurate conception of the state of a ship's hold may be formed by referring to the longitudinal section (fig. 48), which is termed the Jesuit's perspective, or bird's-eye view of the internal part of one side of a seventy-four-gun ship in a complete state, with fillings in the openings between the timbers of the frames, instead of the planking over them.

"In this state the diagonal timbers are introduced, intersecting the timbers of the frame at about the angle of forty-five degrees, and so disposed as that the direction in the fore is contrary to that in the after part of the ship (as may be seen in the engraving), and their distance asunder from six to seven feet or more; their upper ends abutting against the horizontal hoop or shelf-piece of the gun-deck beams, and the lower ends against the limber strakes, except in the midships, where they come against two pieces of timber placed on each side of the keelson (called additional keelsons), for the purpose of taking off the partial pressure of the main-mast, which always causes a sagging down of the keel, and sometimes to an alarming degree. These pieces of timber are nearly as square as the keelson, and fixed at such a distance from it, that the main step may rest upon them. They may be of oak or pitch-pine, and as long as can be conveniently procured. Pieces of timber are next placed in a fore and aft direction, over the joints of the frame-timbers, at the floor and first futtock-heads; their ends in close contact with, and coaked or dowelled to, the sides of the diagonal timbers. In this state the frame-work in the hold presents various compartments, each representing the figure of a rhomboid.

"A truss-timber is then introduced into each rhomboid, with an inclination opposite to that of the diagonal timbers, thereby dividing it into two parts. The truss-pieces so introduced into the rhomboid, are to the diagonal frame what the key-stone is to the arch; for no weight or pressure on the fabric can alter its position in a longitudinal direction, till compression takes place at the abutments, and extension of the various ties.

"This arch-like property of the diagonal frame not only opposes an alteration of position in a longitudinal direction, but also resists external pressure on the bottom, either from grounding or any other cause, because no impression can be made in its figure in these directions, without forcing the several parts of which it is composed into a shorter space.

"The beams are disposed in the new system nearly as usual, except that in midships, where a ship necessarily requires the greatest security, two additional beams have been introduced.

"The beams of the several decks are attached to the ship's side in the following manner.

"1*st*, By shelf-pieces or internal hoops, distinguished by the letter E. These shelf-pieces are composed of several lengths of timber, scarphed or joined together by coaks or circular dowels, so as to form a kind of internal hoop, extending from the hooks forward, to the transoms abaft—(in the plate the transoms are not shown, as we have chosen the perfected application of Sir Robert Seppings' system, after the adoption of the circular stern into the service),—to the under side of which, as well as the under parts of the beams, they are securely coaked, and being then firmly bolted to the side, instead of becoming a mere local fixture of the beam to the ship's exterior frame, as knees were, they are one continued and general security. The shelf-piece is also a tie to the top-side in a fore and aft direction, co-operating with the trussed frame, as already explained.

"2*dly*, By chocks, represented in Plate CCCCLV. (*m*, *o*), which are placed under all the shelf-pieces in wake of the beams, except the orlop, in such a manner as to receive the up and down arm of the iron knees. The lower ends of those under the gun-deck shelf-piece step on the ends of the orlop-beams; and those of the several decks above, step on the projecting part of the spirketing below. The chocks, particularly those between the orlop and gun decks, admit of their being driven into their respective places very tightly, thereby acting like pillars. Another advantage attending them is their great tendency to stiffen the ship's side, and to prevent the beam-ends from playing on the fastenings when the ship is rolling, or straining under a press of sail.

"The curved iron-plate knees for securing the orlop-beams, and the iron forked knees of the other decks, are described in (*n*) and (*m*), Plate CCCCLV.

"The tendency of the ship to stretch or draw asunder in her upper works being by no means obviated by the short planks on the inside between the ports, a truss piece of plank is substituted in lieu of them, which being well secured at the abutments, very materially aids the trussed frame, and gives great stiffness, thereby opposing the inclination to arch or hog aloft."

These various alterations from the old system of building had the effect of very greatly increasing the strength of the ships of the royal navy. Among so many changes, it is not improbable that erroneous conclusions may have been drawn as to the relative importance of each. We incline much to the opinion that this has been the case to a very great degree, and that a part hitherto considered as quite subordinate, and now wholly discontinued as useless, was one principal cause of the increase of strength which enabled ships to preserve their sheer. This we shall presently endeavour to prove.

The diagonal frame.

The lower ranges of riders and trusses, which were brought on the upper surfaces of the floors and first futtocks, could have but little effect in preventing arching beyond that which arose from the additional resistance they offered to compression, and the additional rigidity they gave to the structure in the event of grounding, or of being ashore. They certainly served as a firm base upon which to erect a series of riders with diagonal trusses, which were more advantageously placed to afford efficient support to the extremities of the body. Yet these upper riders only extended to the securities of the gun-deck, and therefore not very far above the line of non-action. Presuming, however, that this second series of riders was of considerable utility, a firm base for them might probably have been obtained without so much incumbrance to the hold, and consequently without the objection being urged against it, which was made to the diagonal riders, of diminishing the stowage. According to the estimates made by Sir Robert Seppings, the actual cubical contents of the diagonal frame were less than those of the ceiling which it superseded.

Trussing between the ports.

The trussing between the ports has been discontinued in Her Majesty's ships. We cannot but regret the change, as we consider this was the most advantageous innovation connected with the diagonal system, and one in which the benefit was unaccompanied with compensating inconveniences.

In investigating the reasons on which we found this opinion, we shall merely describe the manner in which we consider this trussing must have acted, to prevent any alteration of form in the upper parts of the ship.

We commence, then, with the gun-deck of a three-decker. The gun-deck, from its proximity to the line of inaction, from the support of the trussed frame, which extended to its shelf, and from the wales, may be assumed, at least in a new ship, as a most firm base on which to raise a series of supports. At some point on the upper edge of the gun-deck spirketing, a shore, that is, the truss, firmly cleated at its heel, extended upwards and aft, in the after-body of the ship, to the lower edge of the middle-deck clamp, where it was securely cleated; immediately above the head of this shore a second was fixed on the upper edge of the middle-deck spirketing, and extended upwards to the lower edge of the main-deck clamp, where it was secured; and immediately over the head of this shore a third was secured, on the edge of the main-deck spirketing, and extended upwards to the lower edge of the quarter-deck clamp, where it was finally secured: so that a point in the range of securities to the quarter-deck was continuously and firmly shored up from a point in the most rigid and unalterable part of the ship; and, in the same manner, a series of points along the range of securities to the quarter-deck became shored up from the same foundation. This is in the after-body. In the fore-body a corresponding system of shoring ran in an opposite direction forward, and in a similar manner supported the range of securities of the forecastle, while each intervening deck partook of the same advantage.

Radiating as these shores did in opposite directions from the most rigid part of the ship as their base, while they afforded a series of points of support to the principal longitudinal ties, they formed with them a system of triangles; and the triangle is a figure which admits of no alteration of form; for as long as the sides remain the same, the angles are invariable. It might almost be said to be impossible, therefore, for the range of quarter-deck and forecastle securities, by which we mean the clamp, shelf, and water-way, to drop at the extremities, excepting in so far as the compressibility of the materials would admit.

To adapt another, and perhaps a stronger, view of this system of trussing, we may consider the whole top-sides of a ship, with the securities of the gun-deck as a base, to be a series of horizontal ranges of materials, supported by alternations of firmly secured triangles, so placed, that the bases of the superior ranges of these triangles derive firm support from the triangles of the inferior ranges. Considering the unalterability of form of the triangle, and the advantage of the pressure being brought upon the end grain, in which there is comparatively little shrinkage, this is certainly a mode of constructing a top-side which must be possessed of great rigidity. In fact, if there was an error in the system of trussing the top-sides adopted by Sir Robert Seppings, it was, that he did not extend it to the extremities, even round the bow and stern, and also apply a similar system to the short stuff outside between the ports.

The advantages to be derived from triangular combinations of the timber composing the hull of a ship are yet but imperfectly appreciated. We have no doubt that great improvement in ship-building is to be effected by these means, unless, indeed, timber should be superseded by iron, and the stupendous and costly line-of-battle ship be destined to give place to small but powerfully armed steamboats. An iron sailing vessel is being built in Scotland, of between five and six hundred tons burthen. It seems also not improbable that the introduction of so destructive a missile as the hollow shot into naval warfare, will render it expedient to diminish the aggregate loss from their effect, by lessening the size and increasing the number of the vessels used in naval battles. This is, however, as yet merely speculative.

Fill in the en- ings

Another important part of the diagonal system, as it is described in the foregoing account given by Sir Robert Seppings, was the making the bottom a solid mass, by filling in the openings between the frame-timbers. This we have already mentioned as most effective in resisting alteration in form. It possessed a more important advantage, in the immense additional safety it assured to the vessel in the event of grounding, or of starting a but of the plank. The introduction of the system of solid bottoms into the mercantile navy, which Mr Ballingall has so long and so strenuously urged, would be an incalculable advantage, not to the merchant or ship-owner, for the system of insurance is their refuge, but to a class of men of equal value to England with either merchant or ship-owner—seamen, whose lives are often most cruelly sacrificed to the present immunity from pecuniary loss which marine insurance guarantees to their employers.

We are no friends to the system of marine insurance. We doubt much whether the evils which have resulted from it, in the loss of human life, and its attendant miseries to survivors, the system of gambling which it encourages among all classes of commercial men engaged in it, and the fraud and crime which it often occasions, do not more than counterbalance its advantages, which, after all, may be summed up in this, that in the event of shipwreck, the merchant and ship-owner are indemnified for a loss which, in a majority of cases, would not have occurred had it not been for the recklessness and carelessness engendered by the very knowledge that this indemnification was to be purchased. We here advance no unsupported opinion: the Report of the committee of the House of Commons on shipwrecks says, "The system of marine insurance, though affording the means of protecting individuals from excessive loss, has nevertheless a tendency, by transferring the pecuniary responsibility for such losses from the owners of ships to the underwriter who insures them, to induce less care in the construction of ships, less efficiency in their equipment, and less security for their adequate management at sea; in as much as the risk of such loss to the ship-owners can be covered by a fixed premium of insurance, which, being charged on the freight, and then recharged on the goods conveyed, fixes the real responsibility and real loss ultimately on the public; as all the parties actually engaged in the transaction can insure themselves from any participation in such loss, by the aid of marine insurance." This, too, is from the Report of a committee composed principally of merchants, of ship-owners, and of ship-builders. But to return to our more immediate subject, though we can hardly call this a digression, connected as it is with the progress of the science we are writing on.

Modern diagonal supports, and system of building.

The system of wooden riders, longitudinal pieces, and trusses (Plate CCCCLVI. fig. 48), is now discontinued in Her Majesty's ships, and is superseded by a modification of the iron riders or braces, which were formerly only proposed by Sir Robert Seppings for frigates and the smaller classes of vessels. In the recent adaptation of these braces to line-of-battle ships, there are several material differences from the original plan. The ceiling, with its thick strakes over the heads and heels of the timbers, is restored, excepting that the planking between these thick strakes is laid diagonally, as shown in Plate CCCCLVII. fig. 49. There are also two ranges of iron riders; the lower range is brought upon the inside of the timbers of the frame, and the ceiling worked upon and scored over them. The upper ends of this range of riders extend forward in the fore-body and aft in the after-body, and the heads run high enough to turn out upon the orlop clamps, and bolt through them. The riders of the upper range give long shift to those of the lower range, and their direction crosses that of the lower range at right angles. Both ranges are very securely bolted through the bottom.

It will have been evident from the foregoing remarks, that we do not consider the hold as an advantageous situation for any great expenditure, either of workmanship or materials, simply for the purpose of preventing the alteration in the form of a ship.

After having obtained the greatest degree of incompressibility compatible with the materials used, the next object, in this part of the body, should be to insure adequate local strength to resist the strain of taking the ground; and we assume it for granted, that it is for this purpose the thick strakes at the heads and heels of the timbers have been restored, and also that the lower tier of iron riders is worked. The placing the ceiling diagonally between the several assemblages of thick strakes, was probably with an idea that it would act as a trussing; but, according to the views of the action of the disturbing forces which we have taken in this part of our article, it can have little, if any, effect in preventing alteration in form, beyond that of ceiling worked in the ordinary and less costly manner, and is inferior in other respects.

In the upper range of riders the iron bars are placed with their upper ends extending inwards from the extremities of the ship, offering a series of very effective ties, or braces, to connect the unsupported extremities of the vessel to the midship, or supported part, and to the firm basis of the zone about the surface of the water. This series of braces is unquestionably advantageous, and is also correct in principle, as affording support to the extremities of the vessel, by connecting them with the most unalterable part of the fabric, and to that portion which is abundantly supported by the external fluid. We think it probable that the additional strength resulting to the lower part of the vessel from the lower range is scarcely adequate to the additional expense incurred by working them, with all the accessory fastening and fitting. This method which we have described of strengthening the floor, has not near the rigidity to resist damage from grounding, of the system that it has superseded, which certainly did, according to the intention of the inventor, partake of the nature of an inverted arch, or rather dome. It has, however, one, and that too a very considerable advantage, over the wooden diagonal system, as it offers a fair surface for stowage.

The system of iron diagonal riders which we have described is that adopted in line-of-battle ships. There are several variations from this system, in its adaptation to the smaller classes of vessels. The general features are however the same. The modifications all tend more or less to simplify it in its details. There are, however, some instances in which the iron bars have their upper ends extending outwards, towards the extremities of the vessel, probably in order to assimilate them to trusses; but this is evidently, next to the vertical, the least advantageous position they could be placed in.

Stern.

Circular stern.

Of all the modern innovations in ship-building, the alteration from the square termination to the round in the sterns of ships was received with most general reluctance, so wedded is the eye to the forms it has been habituated to gaze upon; yet it may be fairly questioned whether, if cannon had been used for naval warfare when ships were first built, a square stern would have ever been constructed, and also whether the curvilinear termination to a body, every outline of which presents curves to the eye, is not more consistent with the requirements of a correct taste. Be these questions answered as they may, it is certain that the alteration was attended with a great local increase of strength in a part which had always previously been considered the most imperfectly combined in the whole hull. This was in consequence of the various changes in the timbering which were required to maintain the angles in the contour of the square stern. (Plate CCCCLIX.) First, the ends of the transoms were very insecurely connected with the sides of the ship; then the connexion between the counter-timbers and the transoms was equally insecure; and, lastly, the planking along the sides had no connexion with, and consequently formed no tie to, that on the stern. In the round stern, the timbers of the frame continue to give shift to each other, and to be firmly connected together all round the curve of the stern; the various internal supports are uninterrupted; and the principal planking, being continued from side to side, binds the whole together, and makes the stern little inferior to the broadside in local strength.

The object for which the circular stern was introduced was not so much increased strength in mechanical structure, as increased strength in defence from attack. Most of the modifications of the round stern which have been introduced to preserve the appearance of the square form, and yet obtain the same increase of means of defence or of aggression, have been considerable improvements in point of mechanical construction on the old square stern, but they are certainly inferior to the circular stern in strength. This is partly in consequence of the great rake given to them, which also diminishes the advantage that was the object of the original alteration; the increase of the means of attack or defence, as the explosion from the muzzle of the gun will scarcely clear the ship's side.

The great extent to which this rake is now carried is exemplified by comparing the rake of the stern of the Queen, an English first-rate, which is three feet nine inches in ten feet, with the rake of the stern of the Achille, a French line-of-battle ship, which is only two feet two inches in ten feet. We quite grant the beauty of appearance arising from the rake of the stern; but beauty of appearance is not an essential for a ship of war. In fact, we believe that the stern adapted for a ship of war is yet to be designed, and that sterns will eventually be towers of strength, nearly vertical from the counter to the taffrail.

The three modifications of ships' sterns of which we have been speaking will perhaps be more clearly understood by an examination of Plate CCCCLIX.

Bows.

The drawings (Plate CCCCL.) which we have selected for exemplifying the various plans, sections, and lines connected with the draught and the laying off, are those of the Vindictive, a frigate having an important improvement in the form of the bow above water, introduced by Mr Blake, the master-shipwright of Portsmouth yard, by which her battery for chase is very considerably increased in strength and efficiency. These advantages are gained without the loss of any strength, and without the addition of cost, in building; so that it is highly to be desired that this ship should have a fair trial at sea. The stern of this ship is a modification of the circular formed stern, also from the design of the same gentleman.

We shall now proceed to notice some of the peculiarities observable in the French practice of ship-building. The characteristic difference in their system from our own, which would strike an observer accustomed to English ship-building, would evidently be a less expenditure of material.

Frenc ship-b ing.

The French have retained the old system of frames and filling timbers. Frequently the frames are close jointed throughout their height, and the filling frames put up as single timbers, as is shown in fig. 50, Plate CCCCLVIII. The filling timbers are also frequently of fir. Both frames and filling timbers are chain-bolted. There is no shelf under the beams, only a thick clamp, and a wide chock worked upon the short stuff, and up to the beam (Plate CCCCLVIII. fig. 45). There are generally three side binding strakes faced one inch on, and scored one inch over the beams, and bolted together by in and out bolts passing through the water-way, which is also faced and scored in the same manner. These bolts are secured with nuts and screws at the points, on the outside plank.

Water way.

The water-way is not always scored over the beams, but is sometimes brought plain on their ends (fig. 46). The bolts of the binding strakes, which are then also merely brought on to the beams, secure its lower edge; and in both cases it has in and out bolts through the ship's side, to secure its upper edge.

Beam

The method of connecting the beam-ends with the ship's side, which appears to be most generally adopted in the French ships at present, consists of a chock under the beam (fig. 45), securely bolted through the ship's side, the points of the bolts being set up with a nut and screw. The beam-end hooks over the head of this chock. A plate-knee similar in shape to that known in the English service as Roberts' knee is brought on each side against the chock and beam; but these knees, instead of having a short arm against the ship's side for taking in and out fastenings, themselves form the bolt, each knee having an arm which is driven through the side by means of a shoulder worked in the knee, similar to the shoulder of a dog-bolt. The outer end is secured by a nut and screw. The security of the plate-knees to the beam and chock consists only of three screws in each arm, and one screw in the diagonal brace. These screws are not above five inches long. Thus the security of either knee is completely unconnected with that on the opposite side of the beam.

Plank

The wales, diminishing stuff, and plank of the bottom, are all treenail-fastened, the buts are secured with two bolt-nails in the timber on which the but is placed, and a through-bolt is driven in the timber next the but. In some instances the plank is nail-fastened, but whether with nails or treenails it is double fastened. The treenails are not caulked on the ceiling, but wedged with conical wedges. Most of the principal bolts, as those of the water-ways and chocks, under the beams, are set up outside with a nut and screw; and great care is taken to omit the fastening of the wales and outside planking, wherever these bolts can be advantageously made to answer as fastenings for them.

There is no regular system observed in shifting the buts of the plank, as there is in the English service; but the planks are worked to their full length, without reference to the shift: the only rule which appears to be observed is, that

La hing.

there shall be about two feet shift between the buts of following strakes.

Rather an interesting experiment as to the possibility of diminishing the scantling of the timber, to any great extent, which is used for building large ships, is in progress in the French navy. The Surveillante, a large frigate, was built wholly of small timber, about ten years ago, and as yet the reports on the system are favourable.

The following is an outline of the plan on which she was built.

Sm tim-
ber

The keel, stem, and stern-post are formed of various pieces of timber combined as in the section, Plate CCCCLVIII. fig. 51.

The several lengths of the centre piece, or core, are scarphed together, while the side or strengthening pieces only but with plain buts; care being taken that the buts and scarphs give good shift to each other.

There are in this system no other frames than those which form the sides of ports, and the timbers composing these frames are bolted together, without leaving any opening between them, that is, close jointed. The spaces between the frames are filled in with single timbers, or rather with a frame-work of timber fitted together in the manner shown in fig. 52.

The cant-bodies are framed as in the ordinary method, the after-body timbered round to the post without transoms or fashion-pieces.

From the main-deck upwards the scantlings of the frames are not different from those of a ship of a similar size built in the usual manner; but below this line there is a very considerable reduction. This reduction commences at the lower edge of the gun-deck clamps, and there a couple of thick strakes are worked up to the lower edge of these gun-deck clamps, to form an abutment for a series of internal timbers, brought on the inner surface of the timbers of the frame, and crossing them at an angle of 45°, the upper ends being placed forward in the fore-body, and aft in the after-body. These timbers but at their heels on the heads of a series of internal floor-timbers, brought on the upper surfaces of the floors of the frame. These internal floors are laid athwartships. The openings between the timbers of this internal diagonal frame are filled in with wedge-fillings, so that the whole hold presents one smooth surface for stowage.

Wherever there is an athwartship bulk-head, there is a system of riders worked on the inner surface of this diagonal frame, but taking a vertical direction. The timbers of these bends of riders are not wrought side by side, but one series of timbers is worked on the inner surface of the other, and the bolts pass in and out through both, and through the bottom. These riders run up to the lower deck, and a beam is so disposed with respect to each bend of riders, as to be secured to their heads, and form a part of the system. The bulk-heads which necessarily fill in the space between the beam and the riders run diagonally up on either side the middle from a midship pillar to the beam and riders. Each bulk-head is water-tight.

On Launching.

La hing.

Ships are generally built on blocks which are laid at a declivity of about $\frac{5}{8}$ths of an inch to a foot. This is for the facility of launching them. The inclined plane or sliding plank on which they are launched has rather more inclination, or about $\frac{7}{8}$ths of an inch to the foot for large ships, and a slight increase on this for smaller vessels. This inclination will, however, in some measure depend upon the depth of water into which the ship is to be launched.

While a ship is in the progress of being built, her weight is partly supported by her keel on the blocks, and partly by shores. In order to launch her, the weight must be taken off these supports, and transferred to a moveable base; and a platform must be erected for the moveable base to slide on. This platform must not only be laid at the necessary inclination, but must be of sufficient height to enable the ship to be water-borne, and to preserve her from striking the ground when she arrives at the end of the ways.

Launching.

For this purpose, an inclined plane, *a*, *a* (Plate CCCCLVIII. figs. 53, 54), purposely left unplaned to diminish the adhesion, is laid on each side the keel, and at about one sixth the breadth of the vessel distant from it, and firmly secured on blocks fastened in the slipway. This inclined plane is called the sliding plank. A long timber, called a bilgeway, *b*, *b*, with a smooth under surface, is laid upon this plane; and upon this timber, as a base, a temporary frame-work of shores, *c*, *c*, called "poppets," is erected to reach from the bilgeway to the ship. The upper part of this frame-work abuts against a plank, *d*, temporarily fastened to the bottom of the ship, and firmly cleated by cleats, *e*, *e*, also temporarily secured to the bottom. When it is all in place, and the sliding-plank and under side of the bilgeway finally greased with tallow, soft soap, and oil, the whole framing is set close up to the bottom, and down on the sliding plank, by wedges, *f*, *f*, technically called slivers, by which means the ship's weight is brought upon the "launch."

When the launch is thus fitted, the ship may be said to have three keels, two of which are temporary, and are secured under her bilge. In consequence of this width of support, all the shores may safely be taken away. This being done, the blocks on which the ship was built, excepting a few, according to the size of the ship, under the foremost end of the keel, are gradually taken from under her as the tide rises, and her weight is then transferred to the two temporary keels, or the launch; the bottom of which launch is formed by the bilgeways, resting on well-greased inclined planes. The only preventive now to the launching of the ship is a short shore, called a dog-shore (*g*), on each side, with its heel firmly cleated on the immoveable platform or sliding plank, and its head abutting against a cleat (*h*), secured to the bilgeway, or base of the moveable part of the launch. Consequently, when this shore is removed, the weight of the ship forces her down the inclined plane to the water. To prevent her running out of her straight course, two ribbands are secured on the sliding plank, and strongly shored. Should the ship not move when the dog-shore is knocked down, the blocks remaining under the fore part of her keel must be consecutively removed, until her weight overcomes the adhesion, or until the action of a screw against her fore foot forces her off.

French method of launching.

Fig. 55 (Plate CCCCLIII.) will give an idea of a method of fitting the launch which is practised in the French yards. It must be observed, that the plan requires a firm foundation to the slipway, and therefore it is not generally applicable.

The two pieces (*a*, *a*) which are shown in the figure as being secured to the ship's bottom, are the only pieces which need be prepared for each ship; the whole of the remainder will be available for every launch. These pieces were, in the launch fitted to the bottom of a fifty-gun frigate, seven inches thick on their outer edges at the midship bend, and were in length one third that of the ship.

A space scarcely more than half an inch was left between them and the baulk-timber, which was placed beneath them (*b*, *b*), as it was not intended that the ship should bear on these baulk-timbers in launching; they are only to support her in the event of her heeling over. The ship was intended to launch wholly on the sliding plank (*c*), which was fitted under the keel. This sliding plank was, in the case in question, about four inches thick. The groundways were of baulk-timber, laid about four feet apart, extending across the slip; between these groundways stacks of blocks were built, so that the sliding plank was supported along its whole

Launching.

length with scarcely greater intervals than about fifteen inches between the supports. The slip was cut from out of the solid rock.

Launching without subsequent docking.

Fig. 56 (Plate CCCCLIII.) represents a section of a method of launching a ship which has been coppered on the slip, and which therefore need not be afterwards docked for that purpose. This method of fitting the launch avoids the necessity of docking to remove the launch, by not having any part secured to the ship. The two sides of the cradle are prevented from being forced apart when the weight of the ship is brought on them, by chains passing under the keel. Each portion of frame-work composing the launch has two of these chains attached to it, and brought under the keel to a bolt *a*, which passes slackly through one of the poppets, and is secured by a strong fore-lock *b*, with an iron handle *c* reaching to the ports, at which, when the ship is afloat, it may be drawn out of the bolt; the chain then draws the bolt *a*, and in falling trips the cradle from under the bottom. There should be at least two chains on each side secured to the fore-poppets, two on each side to the after-poppets, and two on each side to the stopping-up (fig. 54); and this is only for the launch of a small ship. The number will necessarily increase with the weight of the vessel.

Launchi

Experi- ments o fastenin

We close this article with some most valuable tables of experiments. The first is compiled from one in Moseley's Illustrations of Mechanics, the other three we have been kindly favoured with by Mr Parsons, a member of the late School of Naval Architecture, and formerly belonging to Her Majesty's dock-yard service. These experiments, with a number of others on various securities, were most carefully made by this gentleman; and we regret much that he has not yet made them public to the world, as we are not aware of any similar information being accessible to naval architects or to engineers.

† Drift is an allowance made to insure sufficient tightness in a fastening; it is therefore the quantity by which the diameter of a fastening exceeds the diameter of the hole bored for its reception.

“ In Riga fir the adhesion was on an average about one third of that in oak, and in good sound Canada elm it was about three fourths of that in oak.

“ *Table of the Strength of Clenches and of Forelocks, as securities to Iron and Copper Bolts, driven six inches, without Drift, into sound Oak, either clenched or forelocked on Rings, and subjected to a direct Strain, as in fig.* 57.

“ In the experiments on the clenches, the clenches always gave way; but with the forelocks it as frequently occurred that the forelock was cut off as that the bolt broke; and in the cases of the bolt breaking, it was invariably across the forelock hole. According to the tables, the security of a forelock is about half that of a clench.

“ It appears an anomaly that the strength of a clench on copper should be equal to that of one on iron. But, in consequence of the greater ductility of copper, a better clench is formed on it than on iron. Generally the thickness of the fractured clench in the copper was double that in the iron. With rings of the usual width for the clenches, the wood will break away under the ring, and the ring be imbedded for two or more inches before the clench will give way.

“With the inch copper bolts, all the rings under the clenches turned up into the shape of the frustum of a cone, and allowed the clench to slip through at the weights specified.

“ Experiments with ring-bolts were made to ascertain the strength of the rings in comparison with the clenches. The rings were of the usual size, viz. the iron of the ring one eighth inch less in diameter than that of the bolt. It was found that the rings always carried away the clenches, but that they were drawn into the form of a link with perfectly straight sides. The rings bore, before any change of form took place, not quite one half the weight which tore off the clenches. It appears that the rings are well proportioned to the strength of the clenches.

“ In all these experiments on treenails, when the treenails were evidently good, they gave way gradually. In some of the rejected experiments, however, the treenails certainly did break off suddenly, but then they were evidently on examination either bad or over-seasoned treenails. It is no uncommon remark in caulking down the bottom of a vessel, that the caulkers break off the treenails by caulking, and that they hear them crack or break off suddenly. Now I do not believe that this cracking of the treenails takes place so frequently as it is supposed. What the men hear is the starting of the plank on the different fastenings. It has been asserted that the treenails made from the Sussex oak are much stronger than those made from the New Forest timber, or any other English oak. To ascertain the truth of this assertion, some experiments were made with Sussex and New Forest treenails of all sizes; and the result was, that there was not the least difference in them, the New Forest were on experiment quite as strong as the Sussex.

“ In the experiments on treenails, the plank generally moved about half an inch previous to the fracture of the treenail.”

(B. Z.)

SHIPSTON-ON-STOUR, a town of the hundred of Oswaldslow, in the county of Worcester, but detached from it, and surrounded by Gloucestershire. It is eighty-three miles from London, has little trade except what arises from its great sheep-fairs. It has a large market on Friday. The population amounted in 1801 to 1293, in 1811 to 1377, in 1821 to 1562, and in 1831 to 1632.

Ship-Money was an imposition charged upon the ports, towns, cities, boroughs, and counties of England, in the reign of King Charles I., by writs, commonly called ship-writs, under the great seal of England, in the years 1635 and 1636, for the providing and furnishing of certain ships for the king's service, which was declared to be contrary to the laws and statutes of this realm, the petition of right, and the liberty of the subject, by statute 17 Car. I. c. 14.

SHIRAZ, or SHIRAUZ, a large city of Persia, the capita' of the province of Fars, and, at different periods, of the whole kingdom. According to Fraser, the city of Shiraz is situated in the midst of a brown, barren plain, without a village or any living thing, to relieve it. There were, when he visited the place, only one or two gardens on the wide expanse, which resembled black spots in the desert. He adds, that a nearer view does not present any more favourable impression, the aspect of its mud-walls, surrounded with ruins and broken ground, impressing the most gloomy ideas. Kinneir, on the other hand, gives a different account of its

Shiraz.

appearance, which, he says, is pleasing rather than grand, the city being surrounded with many beautiful gardens. The season of the year when Shiraz was visited by the former traveller seems, however, to have been unfavourable for the display of vegetable beauty; and he accordingly observes, that at this time the richer and irrigated spots were burnt up; and to this circumstance may be traced the discrepancy in the accounts of these two writers. All travellers, however, agree in their account of the interior of the city, which has an extremely mean appearance; the houses are small, and the streets narrow and filthy.[1] Every thing within the town marks the total neglect of even the attempt at improvement. The bazaars and maidans or colleges are falling into ruins; the streets are choked with dirt, and with heaps of ruins from decaying houses; their inmates squalid and insolent, crawling forth in a state of rags and wretchedness, which, Sir R. Porter says, no pen can describe. The impure state of the water brought into the city affords one among many gross instances of public neglect, more especially considering the abundant supply of this pure element with which the city was furnished in ancient times, and the facility with which the spring at the tomb of Sadi, or the limpid rills of the Rocknabad, might again be introduced and distributed for the supply of the city. The town has six gates, and is divided into twelve districts or parishes, in which there are fifteen considerable mosques, besides many others of inferior note, eleven colleges, fourteen bazaars, thirteen caravanserais, and twenty-six mumniums or baths.

Of the mosques, the Mesjed Ali, built in the khalifat of Abbas, is the most ancient, and the Mesjed No the largest. It was converted from a palace to a mosque by Attabek Shah, whose son was lying in a dangerous illness, and who, consulting one of the priests, was answered, that for the recovery of his son he must devote to the Almighty that which of all his worldly goods he valued most. The Mesjed Jumeh is likewise an ancient structure; and there are six others of an older date than the time of Kerim Khan. Of the modern mosques the Mesjed Vakeel, the only one built by this prince, is the most beautiful. Of the colleges, one of the earliest was founded by Imaum Kouli Khan. Kerim Khan began a college which he never finished; and another was founded by Haushem, father of Hajee Ibrahim, the vizir of the late king. The great bazaar, or market-place, was built by Kerim Khan, and forms a contrast to the mean appearance of the other parts of the city. It is about a quarter of a mile in length, made of yellow burnt brick, and arched at the top, with numerous sky-lights, which, with its doors and windows, always admit of sufficient light and air, whilst the sun and the rain are completely excluded. The bazaar is allotted to the different traders in the city, all of whom have their separate quarter, in which their shops are extended adiacent to each other on both sides of the building.

Of the caravanserais, the one built by Imaum Kouli Khan, and now in ruins, is the most ancient. There is another old structure, which was restored from a state of great decay, and assumed the name of its second founder, Ali Khan. There are five others; one for the dressers of sheep-skins for caps, another for dyers, and one for Hindoos. Three other caravanserais were added by Kerim Khan, and two others have been since erected. The ark or citadel, in which the governor of Fars resides, is a fortified square of eighty yards. The royal palace within is far from being an elegant structure; and some of its finest ornamental pillars were removed by Aga Mahommed Khan to adorn his palace at Teheran.

The environs of Shiraz, in its ancient splendour, have furnished a theme for poets, and have been celebrated by Hafiz, the favourite bard of Persia, who was a native of this city, and who is buried in a small garden about half a mile from the town. A monument was erected to his memory by Kerim Khan; it is placed in the court of a pleasure-house which was much frequented by the poet; the building has a small court before it and another behind, and in the centre is an open vestibule, supported by four marble columns, opening on each side into neat apartments. The tomb is placed in the back court, at the foot of one of the cypress trees which he planted with his own hands. It consists of a block of white marble in the form of a coffin, exquisitely carved. One of the poet's odes is inscribed on the marble, and the letters appear as if they had been sculptured with the finest pen, rather than carved with a chisel. Sir R. K. Porter, who visited this tomb ten years after Morier, gives a melancholy account of the decay which has taken place in the interval, from neglect: the spot is no longer held sacred, being covered with promiscuous graves; the trees are gone, and the stone itself, already defaced, will not, unless it be secured from profane hands, long remain the memorial of departed genius. The population of Shiraz has been variously estimated at from 40,000 to 10,000. M. Morier, who was at some pains to make an accurate estimate, says 19,000. The commerce of the city is of some extent, and has been increasing of late years. The principal trade is with Bushire, through whose ports is brought into the country a supply of foreign produce and manufactures, such as sugar, pepper, cinnamon, chintz, glass, hardware, piece-goods, &c. These articles are exported to Yezd and Ispahan, and the manufactures of these cities received in return. The prosperity of Shiraz decayed after the death of Kerim Khan; its commerce was diverted into other channels, and its numerous manufactures perished for want of purchasers. Two, however, have survived, and are prosecuted with diligence and success; one is making glass for windows, bottles, and goblets, which are sold all over the kingdom; the second is the formation of sword-blades and daggers, which are deemed excellent for general use. In the hills which bound the plain of Shiraz, was formerly produced a wine which is celebrated over all the east. Long. 52. 44. E. Lat. 29. 36. N.

SHIRE is a Saxon word signifying a division; but a county, *comitatus*, of the same import, is plainly derived from *comes*, the count of the Franks; that is, the earl or alderman, as the Saxons called him, of the shire, to whom the government of it was intrusted. This he usually exercised by his deputy, still called in Latin *vice-comes*, and in English the sheriff, shrieve, or shire-reeve, signifying the officer of the shire; upon whom, in process of time, the civil administration of it totally devolved. In some counties there is an intermediate division between the shire and the hundred; as lathes in Kent and rapes in Sussex, each of them containing about three or four hundred a piece. These had formerly their lathe-reeves and rape-reeves, acting in subordination to the shire-reeve. Where a county is divided into three of these intermediate jurisdictions, they are called trythings, which were anciently governed by a trything-reeve. These trythings still subsist in the large county of York, where, by an easy corruption, they are denominated *ridings;* namely, the north, the east, and the west ridings.

SHIRT, a loose garment, commonly of linen or cotton, worn next the body. Shirts were not worn by the Jews, Greeks, or Romans, but their place was supplied by thin *tunicæ* of wool. The want of linen among the ancients made frequent washings and ablutions necessary.

SHIRVAN, or SCHIRVAN, a province in the north of Persia, now claimed by Russia. It is the largest and most important division of the Southern Caucasus. It extends along the Caspian, 200 miles from the mouth of the Cyrus, to the little river Rubas; and forms a large triangular peninsula, the point of which stretches into the Caspian. From its form it varies extremely in breadth, which, at the extremity of the peninsula on the Rubas, is scarcely sixteen miles; near Kuba it amounts to forty; from the mouth of the Ata it is above fifty; while in the interior part it amounts to 160. It has the Caspian to the east; Daghestan to the north; the Kur and the plains of Mogam to the south and south-west, being separated by the river Kur from the provinces of Ghilan and Azerbijan; and the kingdom of Georgia to the north-west. The northern part of this province consists of a plain, which is formed by the mountains that extend toward the sea near Derbend, and which, gradually receding behind that city, approach again in a circular form near the sea at the mouth of the river Ata. Numerous streams, issuing from the mountains, greatly contribute to fertilize this plain, and, at the same time, to secure it against the access of an invading army. They branch off in various directions, and being generally mountain-streams, are uncommonly rapid, though they are shallow, with a wide channel, and a rough and sandy bed. The plain is interspersed with small woods and clumps of bushes, and the villages are surrounded with orchards, vineyards, and plantations of mulberries. The second division of Schirvan extends on one side along the coast from the Ata to the plains watered by the Kur; and on the other it is bounded by the higher range of mountains, which run in a south-east course through the province. The length of this district is about eighty miles; but as the coast projects considerably, the breadth varies. The higher portions of the country are here the most fertile; the part towards the sea is barren, being devoid of water; and to the north of Baku is a desert tract of about fifty miles. The plain along the left of the Kur is about 140 miles in length, and from forty to fifty in breadth. The district is in a great degree surrounded with mountains, and, being exposed to frequent inundations, is overgrown with rushes to a considerable distance. The most elevated division of Schirvan is that which extends from the Rubas to Lesgestan. This tract varies much in breadth, and is intersected by narrow valleys, in many of which are small lakes, which continue filled even in the greatest heat of summer. This province is abundantly watered by streams, which fall, some into the Caspian, and others into the Kur. The most considerable are the Samur, Deli, Sagaite, and Persagat. This province was annexed to Persia in the year 1500, and continued subject to that empire till the decline of the Sefi dynasty, when the native princes, taking advantage of the weakness of Persia, re-established their independence. Of late, however, the Russians have obtained possession of the sea-coast, though the interior is still in the hands of the native chiefs. The principal towns are Schamachi, the capital, and Baku.

---

[1] Narrative of a Journey into Khorassan, p. 94; Geographical Memoir of the Persian Empire, p. 62.

SHOAD, among miners, denotes a train of metallic stones, serving to direct them in the discovery of mines.

Shoad-Stones, a term used by the miners of Cornwall and other parts of this kingdom, to express such loose masses of stone as are usually found about the entrances into mines, sometimes running in a straight course from the load or vein of ore to the surface of the earth.

SHOAL, in the sea-language, denotes a place where the water is shallow; and likewise a great quantity of fishes, such as a *shoal of herrings*.

SHOAL-WATER BAY, on the east coast of New Holland, visited by Captain Flinders in 1802. Long. of Aken's island at its entrance, 150. 15. E. Lat. 22. 21. S.

SHOE, a small island in the Pacific Ocean, near the coast of Waygoo. Long. 130. 53. E. Lat. 0. 1. S.

Shoe, a covering for the foot, usually of leather. Shoes among the Jews were made of leather, linen, rush, or wood; those of soldiers were sometimes of brass or iron. They were tied with thongs, which passed under the soles of the feet. To put off their shoes was an act of veneration; it was also a sign of mourning and humiliation. To bear one's shoes, or to untie the latchets of them, was considered as the meanest kind of service.

Among the Greeks, shoes of various kinds were used. Sandals were worn by women of distinction. The Lacedæmonians wore red shoes. The Grecian shoes generally reached to the middle of the leg. The Romans used two kinds of shoes; the *calceus*, which covered the whole foot, somewhat like our shoes, and was tied above with latchets or strings; and the *solea* or slipper, which covered only the sole of the foot, and was fastened with leathern thongs. The calceus was always worn along with the toga when a person went abroad; slippers were put on during a journey and at feasts, but it was reckoned effeminate to appear in public with them. Black shoes were worn by the citizens of ordinary rank, and white ones by the women. Red shoes were sometimes worn by the ladies, and purple ones by the coxcombs of the other sex. Red shoes were put on by the chief magistrates of Rome on days of ceremony and triumphs. The shoes of senators, patricians, and their children, had a crescent upon them, which served for a buckle; and these were called *calcei lunati*. Slaves wore no shoes; and hence they were called *cretati*, from their dusty feet. Phocion also and Cato of Utica went without shoes. The toes of the Roman shoes were turned up in the point; and hence they were called *calcei rostrati*.

In the ninth and tenth centuries the greatest princes of Europe wore wooden shoes, or the upper part of leather and the sole of wood. In the reign of William Rufus, a great beau, Robert, surnamed the horned, used shoes with long sharp points, stuffed with tow, and twisted like a ram's horn. It is said that the clergy, being highly offended, declaimed with great vehemence against the long-pointed shoes. The points, however, continued to increase till, in the reign of Richard II., they were of so enormous a length that they were tied to the knees with chains, sometimes of gold, sometimes of silver. The upper parts of these shoes were in Chaucer's time cut in imitation of a church window. The long-pointed shoes were called crackowes, and continued in fashion for three centuries, in spite of the bulls of popes, the decrees of councils, and the declamations of the clergy. At length the parliament of England interposed by an act passed in the year 1463, prohibited the use of shoes or boots with pikes exceeding two inches in length, and forbade all shoemakers from making shoes or boots with longer pikes, under severe penalties. But even this was not sufficient. It was necessary to denounce the dreadful sentence of excommunication against all who wore shoes or boots with points longer than two inches. The present fashion of shoes was introduced in 1633, but the buckle was not used till 1670.

Shoe of an Anchor, a small block of wood, convex on the back, and having a small hole, sufficient to contain the point of the anchor-fluke, on the fore-side. It is used to prevent the anchor from tearing or wounding the planks on the ship's bow, when ascending or descending; and for this purpose the shoe slides up and down along the bow, between the fluke of the anchor and the planks, as being pressed close to the latter by the weight of the former.

SHOKET, a village of Syria, in the pachalic of Damascus, on the Orontes, 140 miles north of Damascus.

SHOLAPOOR, a town and district of Hindustan, province of Bejapoor, situated in about the 18th degree of latitude. The town is 125 miles south-east from Poorat. Long. 75. 40. E. Lat. 17. 43. N.

SHOLAVANDEN, a town of Southern India, district of Madura, ten miles north-west from the town of Madura. Long. 78. 10. E. Lat. 9. 50. N.

SHOOTING.

The pursuit and destruction of wild animals for security, food, clothing, or pastime, have been amongst the occupations of men in all ages, since the primeval *bruerè* overspread the earth,

> And wild in woods the noble savage ran.

Before the more refined arts are introduced into any country, the chase is a necessity, and the chief business of life. The stronger and more noxious animals are destroyed for individual safety; the weaker for food. It is not until civilization and her handmaid luxury have seated themselves, that the chase becomes a pastime. It does not appear when the sportsman first sprang into existence. There is no corresponding word in any ancient language, since that could not be called a sport which was a necessity. It is probable that in the earliest ages of society the dog was the sole agent employed by the hunter. Afterwards various weapons, manual, missile, and projectile, as the club, the dart, the arrow, were used by the hunter and fowler. Then would follow springes, traps, nets, and all that class of devices for the capture of beasts and birds *feræ naturæ*, comprehended in the term toils. As dogs were employed to hunt quadrupeds, so, in process of time, hawks were trained to bring down birds for the service of their master. The arbalest, or cross-bow, preceded the matchlock, which, however, could scarcely be called an implement of the chase, but which, in the order of succession, brings us down to the rifle, and original fowling-piece with its long heavy barrel and flint and steel lock; and, lastly, we arrive at the double barrels and detant locks of the modern shooter.

In the days of the Saxon and Norman kings, and long previously, the Britons were famous for their skill in archery, both in war and in the chase. The feats of the bow were often introduced into the songs of the bards of the ancient Britons, and into the ballads of the Troubadours.

Archery.

Archery is now confined to shooting at the target. Ladies not unfrequently contend for the prize in this elegant amusement. Their bows, however, are not such as were used by the amazons of yore, nor are those of the gentlemen of the archery clubs such as decided the battle of Cressy.

Falconry.

Falconry, coeval with, and subsequent to the decline of archery, occupied that rank in British field sports which is now enjoyed by shooting. Falconry is of high antiquity; but at what time hawks were first trained to the sport does not appear. Aristotle informs us that "there was a district in Thrace, in which the boys used to assemble at a certain time of the year, for the sake of bird-catching; that the spot was much frequented by hawks, which were wont to appear on hearing themselves called, and would drive the little birds into the bushes, where they were caught by children; and that the hawks would even sometimes take the birds and fling them to these young fowlers, who, after finishing their diversion, bestowed on their assistants part of their prey." Martial has the following epigram on the fate of a hawk:

> Prædo fuit volucrum, famulus nunc aucupis, idem
> Decipit, et captas non sibi, mœrit, aves.

There is no record of trained hawks previous to the time of Ethelred. Under the Welsh laws of Hoel Dha, (A.D. 940), "the falconer has a privilege, the day that the hawk shall bill a bittern, or a heron, or a curlew. Three services shall the king perform for the falconer on such a day; hold his stirrup whilst he dismounts; hold the horse whilst he goes after the birds; and hold his stirrup whilst he mounts again. Three times shall the king that night compliment him at table." Shakspeare often uses the language of falconry. It is chiefly employed in a scene in the second part of Henry VI., wherein the king, queen, lord protector, and cardinal, are the chief speakers; which goes to prove, that the falconer's terms were, at one time, household words at the English court.

Hunting and archery.

Hunting and archery, which were then almost synonimous terms, (for the sport was somewhat similar to what deer-stalking now is, the rifle being substituted for the bow,) were in high repute with the Danish, Saxon, and Norman kings, whence arose the forest laws. Wolves and boars, which formerly infested the forests, were nearly exterminated in king Edgar's time, when that monarch prohibited the killing of deer and game in his woods. The punishment depended upon the will of the king, until the celebrated forest laws of Canute, which defined the rights and privileges of the monarch and others; but those laws were little regarded by succeeding kings, whose arbitrary will afterwards regulated the laws of the forest. "Besides other prerogatives of the Saxon kings," says Selden, "they had a franchise for wild beasts for the chase, which we commonly call forest, being a precinct of ground, neither parcel of the county, nor the diocese, nor the kingdom, but rather appendant thereto." And these prerogatives, he quaintly observes, were maintained, "that the world might see the happiness of England, where beasts enjoy their liberty as well as men." Another old writer says, that "the Saxon kings and the Danish king Canute made no new forests, but were contented with the woods that were their own demesnes, and were never granted to, or possessed by the subject; but the kings of the Norman race, not being satisfied with sixty-eight old demesne woods or forests, depopulated well-built towns and villages, to make to themselves places appropriated to their own diversion only. William the Conqueror laid waste thirty-six towns in Hampshire to make a forest, which still retains the name of the New Forest; and his forest officers exercised such arbitrary rule, as to abridge even the great barons of the privileges they enjoyed under the Saxon and Danish kings, not at all regarding the liberties given to the subject by Canute's forest laws. His son William Rufus is recorded in history for the severity of his proceedings against all that hunted in his forests, inflicting the punishment of death upon such as killed a stag or buck in his forests, without any other law than that of his own will." The killing of deer was punished with loss of sight by William the Conqueror.[1] William Rufus "did so severely forbid hunting a deer, that it was felony and a hanging matter to have taken a stag or buck."[2] In Cœur de Lion's time, the law was very severe against offenders taking the king's venison; it was even unlawful to carry a bow, or take dogs through a royal forest. "Qui arcus vel sagittas portaverint vel canes duxerint sine copulâ per forestam Regis, et inde attaintus fuerit, erit in miserecordiâ Regis."[3]

The forest laws professed to be for the protection of "vert and venison." *Vert* was whatsoever bore green leaves, and afforded food or cover to the deer; and *venison* signified such beasts of the forest or the chase as were the food of man. When reading old books, it is necessary to keep in mind this acceptation of the word venison.

[1] John Selden.

[2] William of Malmsbury.

[3] England's Epinomis, p. 34.

This state of things continued until by the Charta de Foresta the forest laws were better defined and the penalties mitigated. The vast importance attached to the Forest Charter may be inferred from the fact, that although granted by king John at Runnymede, at the same time as the Great Charter, it was not incorporated in it, but was made the subject of a separate and distinct document. The Forest Charter was likewise confirmed by Henry III., contemporaneously with the Great Charter. On the latter occasion the Forest Charter was counter-signed by sixty-four bishops, abbots, and barons; and sentence of excommunication against all persons who should violate it was, with great ceremony, denounced in Westminster Hall, by the archbishop, in the presence of the king, bishops, and nobles, the bishops being robed and bearing torches.

The oath administered, at twelve years of age, to every young man dwelling within the precincts of a royal forest, was in the following rhymes:

> You shall true liege-man be
> Unto the King's Majesty:
> Unto the beasts of the FOREST you shall no hurt do,
> Nor to anything that doth belong thereunto:
> The offences of others you shall not conceal,
> But to the utmost of your power, you shall them reveal
> Unto the OFFICERS of the FOREST,
> Or to them who may see them redrest:
> All these things you shall see done,
> So help you GOD, at his HOLY DOOM

After the Forest Charter was granted any one was allowed to kill game, except in the royal and other forests, and certain other privileged places,[1] until the reign of Richard II., when a landed qualification of forty shillings per annum became necessary to entitle a person to keep "any greyhound, hound, dog, ferret, net, or engine, to destroy deer, hares, conies, or any other gentleman's game." The qualification required was increased with the improved value of land, from time to time, until, in Charles the Second's reign, it was enacted, that persons not having L.100 per annum arising from freehold, or L.150 from leasehold property, or not being of the degree of esquire, or otherwise privileged, should not keep or use "any guns, bows, greyhounds, setting dogs, ferrets, coney-dogs, lurchers, hays, nets, lowbels, hare-pipes, guns, snares, or other engines for taking or killing game."

It was not until the early part of the reign of George III. that killing game was taxed as a luxury, and made a source of revenue to government. A tax of two guineas was first imposed on all persons who should go out in pursuit of game; but the price of the certificate was afterwards raised to three guineas, and subsequently to three and a half guineas. The property qualification is abolished, and now any person who has taken out a certificate and obtained permission from the owner or tenant of the land, in which soever the right at the time may happen to be, is privileged to kill game at all seasonable times. During a long period the sale of game was prohibited, which gave a peculiar value to it, as it was not attainable by any but qualified and certificated persons and their friends, except by indirect means. It is now publicly sold by persons taking out licences for the purpose, and such licenced persons are liable to penalties, and are incapacitated from renewing their licences, should they purchase game from any but duly certificated sportsmen. The licenced dealers are, however, largely supplied by poachers, notwithstanding the penalties to which they subject themselves by trading with uncertificated persons.

Falconry fell into dissuetude in the days of the Georges. It is now scarcely known but by name, although the honorary distinction of hereditary Grand Falconer of England is still extant. As falconry fell into disuse, another kind of sport, which is now considered as disreputable, and practised only by poachers, was pursued by the country gentlemen; the capturing of birds of the game species by means of nets and setting dogs. The dogs were trained to lie down when near to game, and to suffer the net to be drawn over them, so that both dog and birds were entangled in the toil. In this manner partridges are still frequently taken by poachers in the night. A poacher's dog is sometimes known by his habit of crouching when close upon game, and this circumstance not unfrequently leads to a detection of the practices of his master. Netting was considered as a fair mode of taking game until the fowling-piece came into general use.

On the accession of the house of Hanover to the throne of Great Britain, falconry, netting, and shooting, were contemporary amusements. The number of shooters was very limited, the inferiority of the guns and ammunition being such as not to induce their general adoption; hawking was going out of favour; and, of the three sports, netting was the most commonly practised, until the beginning of the reign of George III., after which time it was no longer deemed the sport of gentlemen. At what time the fowling-piece first came into use is uncertain. We learn from Pope that pheasant shooting was in vogue in Windsor forest during the reign of Anne.

Shooting, as practised with guns to which flint and steel locks were attached, may be said to have risen and fallen with the Georgian era. During the latter part of that period, great improvements were made in all the implements and materials of shooting. Double barrels came into use, horse-nail stubs were employed in the manufacture of barrels, the patent breech and percussion-cap were invented, and the wire-cartridge has since been introduced. Not the least improvement has been that in the manufacture of gunpowder. The excellence of our guns and dogs has tended much to spread the love of shooting, which has become the most popular and universal of British field sports.

---

[1] The places privileged were of four descriptions, viz. a forest, a chase, a park, and a warren. To these may be added a decoy for water-fowl, which had also peculiar privileges.

"A *forest* is a certain territory of woody grounds and fruitful pastures, privileged for wild beasts and fowls of forest, chase, and warren, to rest and abide there in the safe protection of the king for his delight and pleasure; which territory of ground so privileged is meered and bounded with unremoveable marks, meers, and boundaries, and replenished with wild beasts of venery or chase, and with great coverts of vert for the succour of the said beasts there to abide; for the preservation and continuance of which, there are particular officers, laws, and privileges belonging to the same, requisite for that purpose, and proper only to a forest and no other place." *Manwood's Forest Laws*, p. 143. "Beasts of forest are properly hart, hind, buck, hare, boar, and wolf, but legally all wild beasts of venery." *Coke's Institutes*, vol. i. p. 233. "A purlieu is a portion of a forest which was disafforested by the Charta de Foresta." *Manwood*, 242.

"A *chase* is a privileged place for receipt of deer and beasts of the forest, and is of a middle nature, betwixt a forest and park. It is commonly less than a forest, and not endowed with so many liberties, as officers, laws, courts, and yet is of a larger compass than a park, having more officers and game than a park. Every forest is a chase, but every chase is not a forest. It differeth from a park in that it is not inclosed." *Manwood*, 49, 147. "Beasts of the chase are, the buck, doe, fox, martern, and roe." *Manwood*, 144.

"A *park* is a large parcel of ground privileged for wild beasts of chase by the king's grant, or by prescription. A park must be inclosed." *Read. Game.* "The beasts of park properly extend to the buck, doe, fox; but in common and legal sense to all the beasts of the forest." *Read. Game.*

"A *free warren* is a place privileged by prescription or grant of the king, for the preservation of the beasts and fowl of the warren, viz. hares, conies, partridges, and pheasants." *Manwood*, p. 44. "If a pheasant, or other bird of warren, flew into a free warren, the falconer could not follow it, but it became the property of the owner of the warren." *Manwood.*

A *decoy* for wild fowl is to this day privileged, in so far as the owner has the exclusive right to the birds frequenting it; and no person is allowed to fire a gun or otherwise make a disturbance within a reasonable distance of it, without permission from the owner.

It has been remarked, that England (Great Britain) is peculiarly the land of sportsmen, the very name being unknown in all other countries. The observation is in a great measure true, for, if we look around the globe, we find that wherever wild animals are killed for the sake of sport, it is mostly by the Englishman. In Sweden the Englishman alone kills the bear for sport. The natives kill it for the sake of reward, or to rid themselves of a noxious neighbour. Their method is generally thus: The strength of the country is summoned *en masse*, and several hundreds of people armed, form a circle many miles in circumference, and march forward until they meet in the centre, by which means great numbers of bears, wolves, and lynxes are destroyed. But this is not done for sport; it is a compulsory matter, and the people engaged in it are paid by the government; it is a species of feudal duty, which the able-bodied are called upon to perform whenever public safety requires it. In Asia, the only sportsman that encounters the royal tiger is the Englishman; the native shekerrie shoots the tiger for profit. There also the buffalo and the boar are hunted by the Englishman alone. In Africa, it is the Englishman who hunts the lion, the hippopotamus, and the giraffe. And in America, it is the Englishman, or English settler, who hunts the panther, the bison, and the bear, for sport; the natives do so from necessity. Since, then, the Englishman is the universal sportsman, it behoves the officer, the emigrant, and the tourist, to make themselves acquainted not only with what may be called the first principles of sporting, but more especially with the sports peculiar to the countries to which they are proceeding, a theoretical knowledge of which may be gleaned from the volumes which annually proceed from the pens of our adventurous countrymen.

The Rifle.

THE RIFLE. The only fire-arms used by the sportsman are the rifle, the musket, and the fowling-piece; the latter may be classified into the swivel-gun, which is fired from a rest, and the shoulder-gun. A short, wide-bored musket, charged with a round or oval iron ball, was formerly used for the destruction of such animals as the lion, tiger, or bear. In modern times, the musket has been superseded by the rifle, and the iron ball by a leaden one, hardened with tin and weighted with quicksilver. A short piece is said to be preferred to a long one for shooting tigers, bears, and the like, as it may be more readily loaded, and is more easily managed in cases of emergency; indeed we apprehend the shooter should seldom fire, except when the animal is so near to him that if he aim coolly, he can scarcely fail to lodge a ball. We subjoin the method of taking aim at wild beasts from practical sporting writers. Captain Williamson gives the following instructions for shooting tigers:[1] "If the motion of an animal through the grass be perceived, the nearest elephant should be halted; and its left shoulder being pointed towards the moving object, is the most favourable position for taking a good aim. The hunter should fire without hesitation, observing to proportion his level as far within the space between himself and the tops of the yielding grass as the height of the cover may dictate; by this precaution, equally necessary when shooting fish that are in any degree beneath the surface of the water, the iron ball will, in general, take effect." Mr. Lloyd says,[2] "If a man purposes attacking a bear at close quarters, a double gun is decidedly the best; if it be in the winter season, a detonator is very preferable. Owing to having flint locks, both my barrels, on one occasion, missed fire, which might have been attended with most serious consequences; a large ball is very desirable. The best points to hit a bear, or any other animal, are in the forehead, in the breast, under the ear, or at the back of the shoulder; bullets placed in other parts of the body of an old bear usually have little immediate effect. If the snow be deep, and the bear is crossing a man, he should always aim very low; he must often, indeed, fire into the snow, if he expects to hit the heart of the beast."

In 1826 it was found necessary to destroy an elephant in Exeter 'Change. A detachment of foot guards were called in, and directed by surgeons where to fire; and 152 bullets were fired before it was disabled. This proves how utterly ineffectual the leaden musket ball would be in the forest. Captain Harris, in his South African tour, in 1837, took with him a double-barrelled rifle, carrying balls two ounces weight, and thus armed, no beast could stand before him. Speaking of the forehead of the elephant, he says,[3] "A ball hardened with tin or quicksilver readily penetrates to the brain, and proves instantaneously fatal." He gives instances of his killing large elephants at a single shot, and seems to have had no difficulty with the "king of beasts," which he has slain "in every stage from whelphood to imbecility." According to Captain Harris, travelling through countries infested by wild beasts is not so dangerous as it is commonly thought to be. He says, indeed, that during part of his journey, "scarcely a day passed without our seeing two or three lions, but, like the rest of the animal creation, they uniformly retreated when disturbed by the approach of man. However troublesome we found the intrusions of the feline race during the night, they seldom, at any other time, shewed the least disposition to molest us, unless we commenced hostilities." He, however, does justice to the terrors of the maned monarch when he says, "those who have seen the monarch of the forest in crippling captivity only, immured in a cage barely double his own length, with his sinews relaxed by confinement, have seen but the shadow of that animal which 'clears the desert with his rolling eye.'"

Fallow deer s ing.

FALLOW-DEER SHOOTING. There are only three kinds of deer in Great Britain; the red, the fallow, and the roe. The fallow deer, which was the dun deer of the days of Robin Hood, is the common deer of the parks. The positions of a stag at rest when fired at may be reduced to three, for each of which a different aim should be adopted. First, when presenting his side to the shooter, the aim should be low behind the shoulder. Secondly, when standing obliquely from the shooter, the aim should be just under the ear, which is a vital part; there is too the chance, when this aim is selected, of reaching the brain through the upper or back part of the cheek, or of striking the animal in some other part of the neck, which will generally bring him down or so disable him that he will be readily recovered. It may be observed here, that the quickest mode of dispatching a dog, horse, or any other domestic animal is to shoot them through the neck, just under the ear. Thirdly, when standing or moving directly from the shooter, the aim should be at the back of the head; thus a chance is secured, should the part aimed at not be struck, of lodging a ball in the neck or spine. When a deer is approaching the shooter, or standing with its head towards him, he should wait until he can have a cross, an oblique, or a driving shot. When a deer is wounded, however slightly, one or more dogs should be instantly slipped. The dogs for this purpose should, as far as practicable, combine the nose of the bloodhound with the speed of the greyhound. A kind of wiry-haired greyhound is used for this purpose in the Highlands.

Deer Stalking. The red deer, which is larger, and the roe-buck, which is smaller than the fallow deer, are found chiefly in the uncultivated mountainous districts of the North. To destroy the deer of an adversary was once a mode of annoyance. Chevy Chase, it would seem, from the three first stanzas of the famous ballad of that name, was an expedition of this description:

> " To drive the deer with hound and horn,
>   Earl Piercy took his way;
> The child may rue that was unborn,
>   The hunting of that day.
>
> " The stout Earl of Northumberland,
>   A vow to God did make,
> *His pleasure in the Scottish woods,*
>   *Three summer's days to take,*
>
> " With fifteen hundred bowmen bold,
>   All chosen men of might,
> Who knew full well in time of need,
>   To aim their shafts aright."

The pursuit of deer with the rifle is termed deer-stalking. To kill the semi-domesticated fallow deer requires little skill beyond that possessed by a good marksman. The skill of the deer-stalker, in pursuit of the red deer, is not only dependant on a good use of the rifle, but is shewn in his ability to find and approach deer; to do which successfully requires the most unwearied perseverance. Many of the Scottish forests wherein the stalking of deer in their wild state is practised, are of immense extent. It is on such tracts of land as the forests of Mar and Athole that the red deer is sought. The forest of Athole alone is said to be more than forty miles long, and in one part eighteen broad, of which about 30,000 imperial acres are devoted to grouse, 50,000 partly to grouse and partly to deer, and there are reserved solely for deer-stalking 52,000 imperial acres. In these vast solitudes, the Highlander stalks the antlered monarchs of the herd, harts which, a century ago, bore the scars of the weapons of his ancestors. An old Celtic rhyme which has been thus Englished, shews the great age to which the deer and the eagle are supposed to arrive.

> Thrice the age of a dog is that of a horse;
> Thrice the age of a horse is that of a man;
> Thrice the age of a man is that of a deer;
> Thrice the age of a deer is that of an eagle.

So far as regards the age of the eagle, these lines contain an assertion which can neither be proved nor negatived. It is different as regards deer. There has long existed a custom of marking fauns that have been caught, and as each forester has a distinct mark known as his own, the age of a marked deer can generally be nearly ascertained.

The deer-stalker has recourse to a thousand manœuvres to approach a herd or solitary stag. The animals are usually descried at a long distance, either by the naked eye, or by the aid of an achromatic telescope, and the mode of approaching them entirely depends upon the situation in which they are discovered. Should it seem impracticable to steal upon them while at rest, the stalkers, armed with rifles, wait in the defiles through which the deer are expected to pass, whilst the attendants make a circuitous movement to get beyond the deer and drive them in the direction required. The deer-stalker, besides being an excellent shot, should have good judgment of ground and a hardy frame, combined with the patience and power to undergo extreme fatigue and privation.

When the red deer is fired at, he is usually at a considerable distance, and perhaps bounding away at full speed. Behind the shoulder, therefore, is the favourite mark. " In killing deer,"[1] says Mr. Maxwell, " it is necessary to select the head, or aim directly behind the shoulder. A body-wound may eventually destroy the animal, but the chances are that he will carry off the ball." Mr. Scrope,[2] whose experience and success in deer-stalking render his remarks valuable, says, " the most perfect shots and celebrated sportsmen never succeed in killing deer without practice; indeed, at first, they are quite sure to miss the fairest running shots. This arises, I think, from their firing at distances to which they have been wholly unaccustomed, and is no reflection upon their skill. It is seldom that you fire at a less distance than a hundred yards, and this is as near as you would wish to get. The usual range will be between this and two hundred yards, beyond which, as a general rule, I never think it prudent to fire, lest I should hit the wrong animal, though deer may be killed at a much greater distance. Now the sportsman who has been accustomed to shot guns, is apt to fire with the same sort of aim that he takes at a grouse or any other common game; thus he invariably fires behind the quarry; for he does not consider that the ball, having three, four, or perhaps five times the distance to travel that his shot has, will not arrive at its destination nearly so soon; consequently, in a cross shot, he must keep his rifle more in advance. The exact degree, as he well knows, will depend upon the pace and remoteness of the object. Deer go much faster than they appear to do, and their pace is not uniform, like the flying of a bird; but they pitch in running, and this pitch must be calculated upon."

The interest and anxiety attending this sport must be as intense as the pursuit is laborious. After climbing for hours the mountain side, with the torrent thundering down the granite crags above him, and tremendous chasms yawning beneath him, the stalker, with his glass, at length descries in some remote valley, a herd too distant for the naked eye. He now descends into the tremendous glen beneath, fords the stream, wades the morass, and by a circuitous route threads the most intricate ravines to avoid giving the deer the wind. Having arrived near the brow of the hill, on the other side of which he believes them to be, he approaches on hands and knees, or rather vermicularly, and his attendant, with a spare rifle, does the same. A moment of breathless suspense ensues. He may be within shot of the herd, or they may be many miles distant, for he has not had a glimpse of them since he first discovered them an hour ago. A moment, and the antlers appear; another, and the herd is in sight. Resting his rifle on the heather, he takes a cool shot at the finest hart, which falls; the rest bound away; a shot from the spare rifle follows, the " smack" of the ball is heard, and the glass tells that another noble hart must die. The dogs, which had been kept far back, are slipped, and are out of sight in a moment. The sportsman follows; he again climbs a considerable way up the heights; he applies the telescope, but nothing of life can he behold, except his few followers on the knolls around him. With his ear to the ground he listens, and amidst the roar of innumerable torrents, faintly hears the dogs baying the quarry, but sees them not; he moves on from hill to hill towards the sound, and eventually another shot makes the hart his own. The deer is then gralloched, and partially covered with peat; the horns are left upright, and a handkerchief is tied to them to mark the spot, that the attendants may find it at the close of the day. Let the reader imagine how much the interest of all this is enhanced by the majestic scenery of an immense, trackless, treeless forest, to which domesticated life is a stranger, where mountain, corrie, cairn, and glen, thrown promiscuously together, present the grandest of savage landscapes, which, as the field of wild adventure, cast into shade what Mr. Scrope calls "the tame and hedge-bound country of the south."

[2] The Art of Deer-Stalking, by William Scrope, Esq., F.L.S. London, 1839.

The Fowling-piece.

THE FOWLING-PIECE. Before making choice of a gun, the shooter should determine what weight he can conveniently carry. The heaviest gun, as regards shooting, will be most effective, but he should recollect that unless he be a very robust person, a light gun will, on the whole, bring him more game, as a few additional pounds in the weight of a gun makes a deal of difference in the distance a person can travel in a day, and, moreover, he cannot shoot as well when fatigued.

The most approved guns under the system which prescribes a heavy charge of powder, and a light one of very small shot, are double barrels, weighing, according to the fancy of the shooter, from six to nine pounds, and bearing the following relative proportions of length to guage: fourteen guage, thirty-four inches long; seventeen guage, thirty-two inches long; twenty guage, thirty inches long. Taking the season throughout, we are convinced, that the most effective gun is a short, wide-bored one, each barrel being charged with rather less than $1\frac{1}{2}$ drams avoirdupois weight of powder, and full 2 oz. of No. 2 shot, containing 220 pellets. This is the general charge, but it may be varied according to circumstances. When game is wild, we would charge the reserve barrel, and, on some occasions, both barrels, with $2\frac{1}{2}$ drams of powder, and a No. 5 blue cartridge for partridges, and with a No. 4 or 5 red cartridge for grouse shooting. No. 7 shot is best for snipe shooting. Small shot may be used for partridge shooting in September, though we do not see any reason for not adhering to No. 2, except that birds very near the gun are liable to be more disfigured by it.

Barrels twenty-six or twenty-eight inches long, and fourteen or sixteen guage, are of convenient size. We think it will not be questioned that these barrels are as efficient as long narrow-bored ones for short distances, viz. under thirty-five yards, and nine-tenths of game brought to the bag is killed within that distance. And for making long shots, the wire-cartridge has obviated the necessity of using long guns. A most material advantage attending the use of a short gun is, the comparative ease with which it may be carried. A pound additional weight at the breech is not so fatiguing to the arm as half that weight added to the end of the barrel; it is the top-heavy gun that distresses the shooter.

Different proportions of powder and shot are required for different sizes of shot. The following may be the proper proportions for a gun not exceeding eight pounds:

Size of shot. No.	Weight of shot. oz.	Weight of powder. drams.
2	2	$1\frac{4}{10}$
3	$1\frac{3}{4}$	$1\frac{1}{2}$
4	$1\frac{1}{2}$	$1\frac{3}{4}$
5	$1\frac{3}{8}$	2
6	$1\frac{1}{4}$	$2\frac{1}{4}$
7	$1\frac{1}{8}$	$2\frac{1}{2}$

These proportions cannot be materially deviated from without destroying the effect. If the powder is decreased, the discharge is weakened; if the powder is increased, the shot spreads; if the weight of shot is decreased, there will not be a sufficient number of pellets for effective shooting; if the weight of shot is increased, the discharge is weakened.

The usual objection to large shot is, that after it has travelled thirty yards it becomes dispersed; but let the powder be reduced to less than $1\frac{1}{2}$ dram, and that objection fails. If it is not overcharged with powder, a gun will shoot No. 2 shot close enough to kill at from thirty-five to fifty yards, with more certainty than if charged with small shot, and two or three drams of powder.

It is not so much the velocity as the momentum of a shot that renders it effective. The momentum of a shot increases in a direct ratio with its weight. The momentum of a No. 2 shot much more than compensates for the diminished weight of powder and additional weight of lead that we have recommended. Large shot droops more than small, and sooner comes to the ground, as it is not carried with the same velocity. It is the momentum, and not the velocity, that the shooter must look to.

We do not suppose that feathers or fur of game present any serious obstacle to either large or small shot; but if they did, the fact that large shot is most effective for shooting wild fowl armed with down, at once tells that it must be so for shooting game which is not so protected. Another advantage of large shot is, that when the aim taken is not quite correct, a single outside pellet will often bring down a bird, when it would require many small shots to do so.

The shooting of barrels depends mainly on three things, viz., the metal of which they are made, the boring, and the breeching. The quality of the metal is of much importance. All barrels expand when fired; and those made of inferior metal expand more than those made of stub-twist. Mr. Greener, in his excellent treatise on the "Gun,"[1] says, "that a barrel is a spring on an extended scale, and the more we can make it partake of the nature of a spring, the better. If we must have expansion, let us have it in its most beneficial form; an expansion that will aid the powder in expelling the lead. This cannot be entirely obtained, nor can the quantity of expansion be entirely destroyed, though you were to make your barrels of the weight of a twenty-four pounder. We must, therefore, decrease it, by making our iron as elastic and tenacious as possible. The qualities of elasticity and tenacity can only be obtained by hammer-hardening the iron. Barrels hammer-hardened will shoot as well without any artificial friction, as those whose friction is extreme, yet have not yet been benefited by the process."

The term friction implies a gradual contraction of the barrel towards the muzzle, which retards the progress of the shot, that more time may be allowed to the powder to burn. "The shooting of all barrels," says Mr. Greener, "depends on a certain degree of friction. The degree of friction necessary varies according to the nature and substance of the metal. Those metals that require least shoot best. The object of the friction is to create a greater force, by detaining the charge longer in the barrel. If, then, there should not be an extra quantity of powder to consume, the friction would be a decided evil." A greater degree of friction is generally allowed to a short barrel than to a long one. A gradual expansion of the barrel towards the muzzle is termed relief. Relief accelerates the progress of shot through the barrels. What is the proper degree of relief or friction for different descriptions of barrels, is a subject fruitful of much controversy; as is also the form of the breech. The best breech is that which will cause the greatest quantity of powder to consume in the barrel.

Mr. Greener would not prevent the barrel expanding when fired, by increasing its thickness, but by improving the quality of the metal. When the barrel expands much, or is held loosely when fired, a loss of strength is induced, as that power which, if possible, should be exerted on the shot, is uselessly expended in a contrary direction, whereas, when the barrel is firmly fixed, and made of metal that only expands in a trifling degree, or, as Mr. Greener observes, operates as a spring, that portion of the explosive force which strikes in any direction, except against the shot, is forced back, or rebounds upon the shot, and consequently becomes a portion of the available strength of the charge. Much of the force that is thrown on a solid fixed surface is returned, but not that which is expended on an yielding one.

---

[1] The Gun, by William Greener. London, 1835

Mr. Greener shews that much loss of strength is induced by barrels not being firmly held when fired; and argues that the mode of proving barrels by allowing them to fly back into sand is defective, as, by reason of the projectiles giving way in one direction and the barrels in the other at the same time, there is not a sufficient strain on the barrels to prove them effectively. On this subject he says, "Let any one take his gun and load it as usual; suspend it by two ropes so as it can fly back; place a quire of brown paper as directly in front of it as possible; fire it, by squeezing the trigger and the back side of the guard together, so as not to displace the gun; examine the impression the shot has made in the paper. If they have stuck in at the distance of forty yards, they have done well. Load again, and fire from the shoulder, and you will find the shots driven through a great number of the sheets. Load again, but first take the barrels from the stock, lest you should happen to break your stock, as I have seen done by a gentleman placing his gun on a stone wall; while he rested, the gun by accident went off and shivered the stock into many pieces, and severely cut his hand by the splintering. (So severe is the recoil from a gun on being fired, when resisted by a solid, unyielding substance. When fired from the shoulder it is different, as the body yields to the recoil, and thus prevents that which would inevitably be inflicted, if the shoulder were placed against a solid substance.) Secure the barrels on a piece of wood, and behind place anything firm; for instance, a piece of lead sufficiently heavy, and that will not injure the end of the breeches, technically called the buts, when they strike it. Having secured them perfectly, fire the barrel in any way you can, and then examine the force of the shots in the paper, and if you do not find that they have penetrated further than they did when fired from the shoulder, say my doctrine is false. It follows, as a matter of course, from these experiments, that in shooting, the more firmly a gun is held to the shoulder, the better it will shoot.

"It is upon these experiments that I found my objections to the practice of allowing best barrels, when proved, to fly back into sand. Such a mode of proof is of no use. Were they fixed like common barrels, the force of the proof would be increased one-half. I doubt whether the present method be any test at all. I am satisfied that the force exerted in this mode of proof on the barrel, is not equal to the pressure of a large sporting charge, when fired from the shoulder.

"The fact that the shooting powers of a gun are increased by its being fixed in an immoveable frame, is proved with the practice of mortars. Mortars on iron beds, and these firmly embedded in the earth, will throw a shell farther when on the ground, than when placed on a platform, or on board a ship. It is for the purpose of destroying the recoil, that mortars for sea-service, though of the same calibre as those intended for land-service, are made three times the weight. Dr. Hutton states, that he found no advantage by retarding the recoil in practice with artillery. He means, that no advantage is gained by stopping at three feet a gun accustomed to recoil to the distance of six. The statement is perfectly true. If he were to allow a gun to recoil only an inch, and then strike against a solid substance, he would gain nothing. For if it recoil ever so little, the shooting force is as much weakened as if it recoiled twice as far.

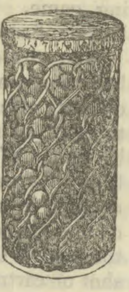
"To increase that force, a steady fixed resistance is required. The velocity of the projectile depends on the force of the immediate impulse. Before a gun, suffered to recoil, could rebound from striking some solid substance in its recoil, the charge would be gone, and could, therefore, receive no additional impetus from that rebound. The truth of this fact may be illustrated by throwing a hand-ball against any loose body with sufficient force to displace it. However hard or elastic that body might be, the ball would not rebound from it, but would fall perpendicularly down. Fix and secure that same body, and then the ball will rebound with little less force than that with which it was thrown against it. So it is with gunpowder. If it meet with a firm resistance, it will rebound and project the ball or shot with additional force."

On Charging the Fowling-piece. It may be premised that all powder, before being put into the barrel, is more or less damp; and most barrels, especially if they have been only imperfectly cleaned, or have been fired and laid by since being cleaned, are also more or less liable to damp. A portion, therefore, of powder should be flashed off in each barrel immediately before charging, for the triple purpose of expelling damp, proving whether the passage through the pivots on which the caps are to be placed, is open, and warming the barrels, so that any little moisture in the charge of powder may be absorbed. The barrels are then held perpendicularly and the powder poured in, in such manner that the whole charge may reach the bottom; and a wadding is then pressed down upon it. The shot is next poured in and another wadding pressed upon it. The shooter next removes the remains of the caps, and looks whether the powder has found its way to the orifice of the pivots, and if it has, he places fresh caps on. If the powder is not visible at the orifice of the pivots, he removes any obstacle with a pen-knife or pricker, and contrives to push down a few grains of powder.

Wire-cartridges.

Wire-Cartridges. The wire-cartridge (fig. 1.) was invented in 1828 by Mr. Jenour. It consists of a cylindrical case or net-work of wire, the meshes of which are somewhat more than an eighth of an inch square; at the lower end the wire partially closes; the wire case is then enveloped in fine paper, and at the upper end a cork wadding, cut so as to fit the guage of the gun, is affixed; the case is then filled with shot and bone dust. The first cartridges made, though ingenious in construction, were defective in operation. It was a matter of no ordinary difficulty to fabricate them in such a manner that the shot should leave the case at the precise distance required. This at first, could not be done so that they might be trusted in every instance. Every alternate cartridge might fire well; but the rest would fire irregularly, being liable to ball; that is, the shot would not leave the case until fifty or sixty yards from the gun, and such cartridges were, of course, not only useless but dangerous. They have been from time to time improved, and almost every difficulty has been overcome. The sporting cartridges now made never ball; they act with a considerable degree of precision and certainty; and that they may be safely trusted may be inferred from the fact that they are often preferred by persons engaged in pigeon matches. Various materials were used experimentally to fill up the interstices between the pellets, but nothing seems to answer so well as the material now used. Another difficulty in their construction presented itself. It was requisite to accommodate them to the various methods of boring pursued by different gunmakers, and the unequal length of barrels, the object in view being to produce a cartridge that would suit all barrels of the same guage; and this has been, in a great measure, if not wholly, accomplished. The liability to ball which, notwith-

Fig. 1.



standing various improvements made in them, was not effectually obviated for many years, during which they were tried, and in many instances prematurely condemned, either from real defects, or from the parties not knowing how to use them. They were not brought to perfection until the year 1837.

The wire-cartridges possess two principal advantages over loose shot; they are propelled with greater velocity, and thrown more evenly. A loose charge is always thrown in patches; the shots of a cartridge, as seen on a target, are comparatively equi-distant from each other. There are four classes of wire-cartridges, which the patentees have named the *battue*, the *blue*, the *red*, and the *green;* each intended for a different range. There is some little difference in the construction of each of the three kinds; the meshes of the frame-work are larger in the battue and the blue than in the red, and in the red than in the green, and there are doubtless other differences not perceptible to the uninitiated. The battue and the blue cartridges are intended for general use; the battue for the shortest distance; the blues will kill several yards further than loose shot of the same size, and of the four kinds, are, in our opinion, decidedly to be preferred; each blue cartridge being thrown more nearly alike, they are more certain in their operation than the red and the green, which are intended for longer distances. The red may be serviceable in open places, when game is wild, and the shooter is provided with a gun of not less than fourteen guage, or with a very short barrel, which does not throw its shot very strongly. The green cartridges are intended chiefly for wild-fowl shooting; these should be used in barrels of not less than twelve guage. The red and green cartridges retain the shot in the case longer than the others, and are carried with an astonishing force to an incredible distance, and at the same time very closely. The red may generally be trusted for long distances, especially from barrels of large calibre; but at short distances the smallness of the circle they describe renders them objectionable. The green cartridges should never be used for shooting game. The blue and battue only should be used in barrels of small guage.

The wire-cartridges do not require either a greater or less charge of powder than loose shot, but there is this peculiarity attending them. A heavy charge of powder throws the shot from the cartridge more closely than a small charge, by reason of its allowing more time for the escape of shot from the net-work. This is exactly the reverse of the manner in which the loose charge acts. The greater the charge of powder when loose shot and wadding are used, the more is the shot dispersed, and *vice versâ*. Either loose shot or cartridge shot is projected with greater force and velocity when a heavy charge of powder is used. When birds lie well, we would recommend the shooter who adopts the cartridge to charge lightly with powder, to give the shots time to spread well; when moderately wild, we would charge lightly with powder in the first barrel, and heavily in the reserve barrel; but when birds are very wild, both barrels should be charged with as much powder as the shoulder can conveniently bear, so as to give the charge the greatest possible force, and at the same time the greatest practicable degree of closeness. It is at long distances that the superiority of the cartridge is conspicuous; when the loose charge is used, the increase of force that is obtained by loading heavily only tends to dispersing the shot, thereby rendering the increased momentum of little avail.

Amongst the advantages attending the adoption of wire-cartridges, it may be mentioned, that the recoil is not so severe, and consequently a lighter gun may be used, than with the loose charge, and this is a great relief to the shooter in a heavy country, and especially on the hills in August, when the heat of the sun is frequently overpowering. The cartridges act well when fired from short barrels, perhaps more satisfactorily than when fired from long ones. The increased facility and expedition of loading is another advantage which should not be overlooked.

The main objection to wire-cartridges, and it is a material one to a person who is an indifferent marksman, is, that they do not describe a sufficient circle at short distances. When game is wild they are invaluable for the reserve barrel of a double gun.

The wire-cartridges usually kept on sale contain, for the different guages, the following weight of shot.

Calibre.	Weight of shot.
20	$\frac{7}{8}$ os.
19	1
18	1
17	1
16	$1\frac{1}{8}$
15	$1\frac{1}{4}$
14	$1\frac{1}{4}$ oz.
13	$1\frac{3}{8}$
12	$1\frac{3}{8}$
11	$1\frac{1}{2}$
10	$1\frac{3}{4}$

When ordering cartridges, it is necessary to give the *guage* of the barrel, the *weight* of the cartridge, the *size* of shot, and the *description*; that is, whether battue, blue, red, or green.

The green cartridges, fired from a common-sized fowling-piece, are not to be depended upon for any distance nearer than fifty yards; and, for that reason, they should only be used for wild-fowl shooting, for which sport they may answer very well when fired from a reserve barrel. We would not recommend their adoption, even for wild-fowl shooting, to a person using a common-sized single gun, since by so doing he would hazard missing when the most favourable opportunities of killing presented themselves. A No. 3 red cartridge would suit better.

The wire-cartridge has been proved to be much superior to the loose charge for the stanchion, and heavy shoulder guns used on the sea-coast and rivers. For the largest shoulder guns, B or BB loose shot, or a No. 1 cartridge is usually adopted. AA loose shot, or a B or No. 1 cartridge will better suit the stanchion gun.

Takin aim.

TAKING AIM. As the manner of taking aim is a matter of primary importance to success in shooting, a few observations on that head may not be misplaced here. When the dog points, or when birds rise near to him, the shooter should immediately draw back both hammers with the right thumb;[1] but should the birds rise at a considerable distance, to save time he need only cock one barrel, as in this case, he has only to fire once. He should never be in haste. It is more prudent to let the bird escape than to fire hastily. If on open ground, he should not fire until the bird is at least twenty-five paces distant, by which means he avoids, on the one hand, the hazard of mangling it, and, on the other, a probability of missing; for at the distance of from twenty-five to thirty yards, whether the piece be charged with loose shot or the wire-cartridges, the range of the whole charge will be wide, yet the pellets will be so close together that nothing can escape, if the aim be true, and, what is of no less moment, the finger also obedient to the eye. He should be deliberate in bringing up the piece to his shoulder, and in making it to bear on the object, but the moment he has brought it to bear, the finger should act in co-operation with the eye, the eye being kept open the while, so that the shooter may see whether the bird falls, or feathers fly from it; for if he does not, he may rely that there is something defective in his system of managing the fowling-piece. A shooter only requires coolness, a very little mechanical knowledge, and a gun properly mounted. Possessing these requisites, he will not be deficient in any other which he will not be easily able to supply. The novice should learn to shoot high enough at winged, and low enough at footed game, and well forward at both. He should seldom shoot directly at the object; but at the wing, if the bird is moving obliquely from him, the head, if the bird is rising, the legs, if descending; but if crossing, or flying obliquely at a considerable angle, he should make an allowance of a few inches according to the distance of the object from him. It is not usual to shoot at any object approaching the shooter. It should be allowed to pass, when he turns round and fires at it as it moves from him.

---

[1] Many experienced sportsmen disapprove of the practice of cocking both barrels at the same time. They think that it ought to be a rule never to cock either barrel, until the game be upon the wing, then that the left barrel should be cocked and fired, and thereafter taken from the shoulder. The right barrel should then be cocked and fired if necessary; if not discharged, it should be put back to the half cock, and the left re-loaded.

Th Rook.

The Rook. We commence our notice of the different kinds of shooting with the fowling-piece now chiefly practised, with a few observations on those birds, not coming under the denomination of game, which occasionally afford the first lessons to the younger brethren of the trigger, and which therefore may properly take precedence, in description, of the more difficult branches of the art.

Young rooks, in the month of May, are generally shot whilst sitting on the branches, near their nests, on the tops of the loftiest trees, so that it requires a steady aim, and hard-stricken shot to bring them down with certainty; for if only wounded, they will frequently cling to the bough with their claws, and die suspended in that manner. The rook should be fired at with a small charge of rather large shot, and a heavy charge of powder. Rooks are gregarious, and feed on grain, worms, and insects. It is only during the season of incubation, and until the young ones can fly, that they frequent the rookery, which is mostly a small plantation, or clump of old trees, and near to some habitation. When rooks choose any particular cluster of trees, or plantation to build in, the same trees will, if standing, be tenanted again the next year by the same rooks and their offspring, notwithstanding they may have been much fired at, or in some other way disturbed. This opinion is not universal. In some counties there exists a prejudice against the practice of firing at rooks with gunpowder, especially when the rooks are few, and the number of trees limited, lest the rooks should desert the rookery; and, therefore, that as little alarm as possible may be created, they are fired at with balls from the air-gun, and sometimes the young shooter will try his skill with the cross-bow. The old rook is distinguished from the young one by the thick end of either mandible being white; and the beak of the young rook is black to the insertion. They are distinguished from other birds of a somewhat similar appearance, by a slight variation of colour; the rook has a blue, the carrion-crow a brown tinge, the jackdaw is partially grey, the raven is jet black.

After young rooks have been fired at several times, some of the strongest and best-fledged will quit the rookery, and alight on hedges or trees at some distance, where the shooter flushes them, and they afford good sport to the tyro learning to shoot birds on the wing. A warm sunny day is best for rook-shooting. In cold weather, particularly on windy days, young rooks will not quit their nests.

The ood-pigeo

The Wood-pigeon. The wood-pigeon is little regarded by the sportsman. A shot may be obtained by lying in ambush early in the morning, near to some wheat stubble, or field of newly-sown grain, where the birds feed; but the best sport the wood-pigeon affords is at the roosting places, where the shooter ought to take his station an hour before sunset. It is difficult to obtain a shot in any other manner, except when the birds are young, when they are sometimes killed in trees, in the same manner as young rooks. The shooter in pursuit of game often sees them, but rarely obtains a shot at them. Sometimes, but it is usually when he is not aware of them, they will suffer him to approach close to the tree in which they are perched. The tree is generally a large one, and perhaps in full foliage, and the shooter hears the rustling of the wings of the decamping birds, but seldom secures a shot. Whenever a wood-pigeon leaves a tree, the shooter should prepare for others, since, when there are several in the same tree, they will not leave it simultaneously, but move off in succession. They are large strong birds, and require heavy shot to bring them down.

Shooting tame pigeons is becoming a very common amusement; but it is oftener practised to decide a wager, than prove the skill of the parties. The Red House at Battersea, near London, is the scene of the principal matches. The birds are sprung from a trap, which is usually placed twenty-one yards from the gun; the birds of each person are provided by his opponent; blue rocks are the favourites; very heavy guns are used, but the weight of shot is usually limited. The birds must fall within a limited distance from the trap, or they are not counted amongst the successful shots.

The Lark, &c.

The lark, field-fare, lapwing, golden plover, and dottrel. Larks and field-fares are often the object of the young shooter's pursuit. Field-fares, the blue-backs and red-wings, arrive in October, and remain during winter. They are easily approached during a frost, or when the ground is covered with snow. They will then be found in search of the berries of the mountain-ash, the holly, and the hawthorn, and are killed in great numbers. Like wood-pigeons, field-fares do not leave a tree, or rise from the ground simultaneously, so that when one bird flies off, if the shooter will hasten to the spot, he will, in all probability, meet with a lagger.

The lapwing or pewit is a bird much sought for by the juvenile shooter. Lapwings are commonly found on marshes, or wet land abounding in rushes. Except during the season of incubation, they collect in flocks, and are so very wary as to be difficult of approach. They are often killed for the sake of their toppings, which are useful to the angler. As they wing round the shooter, it is extremely difficult to decide whether they are within range or not; they should be within a moderate distance when fired at, or they will escape in the interstices of the charge, as the size of the body bears a small proportion to the apparent size of the bird when on the wing. It is not uncommon to see several feathers cut out of the wings, and the bird fly away as if unhurt.

All these birds afford amusement chiefly to schoolboys. The sportsman in pursuit of game does not think them worthy attention; but the golden or whistling plover, and the dottrel, which are birds often met with in hilly districts, are generally considered as worth firing at, if they accidentally come in the way, but are not worth the trouble of following.

The Land-rail.

The Land-rail. The land-rail or corn-crake is a bird of passage. It may be found with pointers or spaniels early in spring, in hedges or long grass. The dogs for this sport should not be staunch; such as will foot the birds are best as it is with great difficulty they can be made to rise. It is only during the first fortnight after their arrival that they may be fairly killed in spring; after that time they begin to pair. In August and September, the sportsman sometimes casually meets with a land-rail, whilst beating for other birds.

Wild fowl.

Wild-fowl. Wild-fowl shooting is practised in various ways. The method of proceeding depends entirely on the situation in which the shooter expects to find the birds. In some of the inland counties, except during hard frosts, they are not met with anywhere but on large pools and rivers, and are only to be approached by having recourse to some stratagem, as waiting in a shed, or on an island, or on the banks of a pool, or stalking behind a horse trained to the purpose. The largest shoulder gun that is at hand may be used charged with the red or green wire-cartridges, the size of shot being regulated by the bore of the piece.

During a severe frost, wild-fowl are compelled to leave the pools, and are then found in small rivers, brooks, or in drains where there are springs of fresh water. The flights being broken, ducks are found singly or only few in number, and are consequently easy of access, and may be shot with a common fowling-piece. The size of shot should be No. 2, or 3. Wild-fowl are so fortified with down on some parts as to resist any but hard-stricken shot. Their back is the most vulnerable part, and all kinds of wild-fowl present it to the shooter as they rise. They are also easily brought down when they present a cross shot; but when approaching it is not advisable to fire at them. If a dog accompany the shooter, it should follow at heel. As the shooter pursues the course of a river or brook, he should keep out of sight as much as possible, and come suddenly on every turn or winding. When there is a mist during a frost, wild ducks will remain in the brooks and gutters all day. The earlier in the morning the better for this sport. Ducks may also be killed on the wing, on the verge of night, by the shooter lying hid near to fresh water springs. If it be a dark evening, he need only wait about a quarter of an hour, but if moonlight he may wait about an hour. They may also be walked up on a moonlight night, when, if they rise above the horizon, they may be killed almost as easily as in the day time. The objection to night shooting is, that birds knocked down are often lost. These are the principal methods by which ducks are killed by any but professed wild-fowl shooters.

The larger kinds of wild-fowl, such as hoopers *(wild swans)* and geese, can rarely be brought down by the common fowling-piece, unless struck on the head or back. Wild-fowl shooting, in creeks and harbours on the sea-coast, is conducted in a very different manner, and on a larger scale of operations. There are two kinds of guns used for the purpose, the shoulder-gun and the punt-gun; the latter being fired from a rest, or frame, or carriage, either in a boat or some other floating craft. Mr. Greener, to whose work we have already referred, says, "Never make duck guns (shoulder-guns) above seven-eighths in the bore, if you wish them to kill at a great distance, and not less than fifteen or sixteen pounds weight, and full four feet long." Colonel Hawker,[1] who has devoted nearly one hundred and fifty pages to the subject of wild-fowl shooting, says, "The barrel of a punt-gun, to be in good proportion, should, I conceive, (including the patent plug, of about six pounds weight, and from two to three inches in length), be about seventy or eighty pounds weight, from seven to nine feet long, and from an inch and a quarter to an inch and a half bore, according to the one length and weight, or the other. The smaller the bore is, in reason, the further you can kill at a small number of birds; but the larger size of these two shoots the best, and is the most regular pattern. Any thing beyond that size seldom answers." Both these writers seem to agree that the common punt-gun, though it weigh eighty or one hundred pounds, cannot be charged to the extent of its shooting powers, by reason of the tremendous recoil that would result; but each advises that the additional weight should be gained by using the barrels double. Thus more than a double advantage would be secured, for not only would there be two barrels at command, but the discharge from each barrel would be more effective. The charge of shot for a punt-gun averages from ten to twenty ounces; the shot is much larger than any used for shooting game.

The Colonel, and we apprehend he is the only practical writer on this department of the subject, describes the various kinds of punts (which are flat-bottomed boats or canoes, so constructed as to be manageable either on sands, or in mud, or water,) used in several different counties, and gives the following directions for shooting wild-fowl, from a punt, with a large shoulder-gun. "Sit down on some straw or rushes, with your gun by your side, and take with you a small Newfoundland dog. Row about, till you can see or hear a flock of wild-fowl on the mud. To find them sitting, if by night, look at first very low, so as to bring the surface of the mud in contrast with the horizon, by which means you will overlook the black edges of the creeks and holes, instead of seeing, and perhaps mistaking them for birds.

"When you have rowed within two or three gun-shots of the fowl, take in your oars, and reconnoitre the creeks. Having ascertained which is likely to be the best, lie down, and push along with the *setting pole* or *gunning spread*, and while the mud banks stand above the little channels, you are so completely hid, that you will seldom fail to get a shot, provided there is a creek within reach of the birds, and you do not go directly to windward of them.

"On arriving sufficiently near, should the water be so low that you cannot present your gun at the birds without kneeling or standing up, you must get aground at the side of the creek, or steady your canoe by means of forcing each oar from between the *thowls* into the mud, otherwise the recoil of the gun will set her rocking, and thus you might probably be tipped out. Having made all fast, rise up and fire. Take care, however, to rise high enough to be well clear of the mud, or not a feather will you touch; and present as follows: By day, or moonlight, if the birds are close, directly at them; or if beyond forty yards, shoot at their heads; unless they are feeding in a concave place, where the tide has left a kind of plash, in which case you must level rather under them, or you will only graze their back feathers. In star-light, take your aim just at the top of the narrow black line, in which birds always appear to one who is low down; and when so dark that you cannot see your gun, present, as you think, about a foot over, or you will most likely shoot above a foot under them.

"Should you have been successful, you will, if at night, generally hear your cripples (wounded fowl) beating on the mud, before you can sufficiently recover your eyes, from being dazzled by the fire, to see them. Your man then puts on his mud-boards, (which are flat square pieces of wood fastened to the feet, to enable the party to walk or wade through mud), taking the setting pole to support him, and assist the dog in collecting the killed and wounded; taking care to secure first the outside birds, lest they should escape to a creek. During this time you are left in charge of the punt; and should, if possible, keep a look out, in order to see if any more birds fall dead or wounded from the company, before they have flown out of sight.

"The gunner generally calculates on bringing home the half only of what he shoots, from the difficulty of catching the whole of his winged birds, which he calls *cripples*, and those that (to use the pigeon phrase) fall out of bounds, which he calls *droppers*. If the birds fly up, he generally declines firing, knowing that the moment they are on the wing, they become so much more spread, that he could seldom get more than three or four, for which it would be hardly worth while to disturb the mud; particularly as widgeon, by night, if not fired at, will, in cold weather, probably settle again at no great distance.

---

[1] Instructions to Young Sportsmen. Eighth edition. London, 1838.

"In following wild-fowl, it is easier to get within twenty yards of them by going to leeward, than a hundred and fifty if directly to windward, so very acute is their sense of smelling.

"The best time, therefore, to have sport with a canoe and a shoulder-gun, (provided it be low water, or half ebb, while you are hid in the creeks), is in clear, frosty, moonlight nights, when the wind happens to blow towards you as you face the moon. It is then impossible for the wild-fowl to smell you; and you may, by getting them directly under the light, have the most accurate outline of every bird, and even distinctly see them walking about, at a much greater distance than a gun would do execution. From thus being on the shining mud-banks, they appear quite black, except some of the old cock widgeons, on the wings of which the white is often plainly to be seen.

"It does not follow, however, that nothing can be done without a bright moon. So far from it, that some of the best shoulder-gunners in the kingdom prefer but very little moon, even for the mud. Here, by constant habit, they can easily distinguish the black phalanxes of widgeons from the shades on the places they frequent, and particularly if they are feeding among the puddles which have been left by the tide. In this pursuit, and when not favoured by the best of light, there are a few cautions to be given to an inexperienced shooter. First, to ascertain that the black patch to be seen *is* a flock of birds, which he will do, by observing the occasional change of feature in the outside of it. Secondly, on approaching them, to be careful that their enormous masses and tremendous noise do not deceive him in the distance, and tempt him to fire out of shot. And, thirdly, not to be too eager in getting his dead birds, as it sometimes happens, in hard weather, that the remainder of the flock will again pitch down among them, particularly if he has winged some of the younger birds, which have not the cunning to make off for a creek, like the old ones. In this case, a reserved gun would, probably, more than double the produce of his first shot. It should be understood, that this night shooting is chiefly at the widgeon, as the geese, of late years, (since there have been so many shooters), have seldom ventured much in harbour by night, except sometimes at high spring tides, with a full moon; and the greater part of the ducks, teal, dunbirds, and such like, repair inland to the ponds and fresh springs, unless driven to the salt feeding ground by severe frost.

"A company of widgeons, when first collecting, may be heard at an immense distance, by the whistling of the cocks and purring noise of the hens; but when they are quietly settled, and busy at feed, you sometimes can only hear the motion of their bills, which is similar to that of tame ducks."

Geese, ducks, widgeons, hoopers, curlews, and other wild-fowl, are killed in this manner; but the most destructive method of killing them is with the heavy stanchion or swivel punt-gun, used by the persons on the coast who make a trade of wild-fowl shooting. When a fair shot can be obtained by this method, from twenty to fifty birds may be killed at one discharge; but it is laborious, wearisome work, and, except for a single occasion, can scarcely be called sport. This kind of shooting is carried on in the night, usually in frosty weather, at which time sailing about on water, or working the canoe through mud, cannot be accompanied with very agreeable sensations.

The size of shot for punt-shooting should, in some measure, be regulated by the size of the birds expected to be met with, and their degree of tameness; yet it is well to be prepared with shot of sufficient size, as hoopers, geese, and other large birds, are sometimes found when least expected

The Water-hen, &c.—There are various kinds of wild-fowl, which will dive rather than fly away when disturbed. They are, for the most part, clumsy birds on the wing, and are killed without difficulty when they can be made to rise. When shot at swimming, the shooter takes aim, and fires instantaneously, or they will be under water whilst he is drawing the trigger.

Dogs.

SPORTING DOGS. Before noticing the different kinds of game which are the object of the shooter's pursuit, a few observations on sporting dogs may not be irrelevant. The shooter's dogs are of four kinds; the pointer, setter, spaniel, and retriever.

Pointers and setters.

Pointers and Setters. If dogs were unknown in Europe, and some traveller from a distant part of the southern hemisphere were to relate that he had seen a new species of quadruped with wonderfully fine olfactory nerves, by the aid of which it was enabled to hunt to death the hare, stag, fox, or jackal, the tale would readily be credited; for the instinct of the hound, as compared with that of other animals, is not such as to excite surprise. But were the traveller to relate that he had seen a quadruped which, untaught, would stand motionless, as if converted into a statue, on coming in contact with the slightest scent of game, he would not be believed; it would appear incredible, such is the extraordinary instinct of the pointer and setter. We use the term *extraordinary* advisedly. There are other animals, and indeed other dogs, which possess a degree of instinct more nearly approaching to reason, but none possessing so extraordinary an instinct, an instinct not analogous to that of any other living creature that we are aware of. The pointer seems to be endued with it for the exclusive service of man; whereas the instincts of all other animals are conducive to the supply of their individual wants, and their usefulness to man is secondary thereto. It would be difficult to controvert the argument that this instinct was given to the pointer for the purpose of aiding men to capture or kill game, by means of such engines as nets or guns. This, we are aware, may be a doubtful position to maintain; but who can say for what other apparent purpose this peculiar faculty was given? It may, indeed, be urged, that the propensity to point, in the pointer, is a means ordained by providence for his subsistence in a wild state, by enabling him to approach within reach of his prey, and thus to accomplish, by another species of stealth, what the tiger and other animals of the cat tribe effect by ambuscade. Such an argument, however, is presumptively rebutted by the fact, that all existing races of wild dogs are gregarious, and resort to the chase for food; nor is there any record of the existence of dogs in a state of nature, except those calculated for the chase. It is therefore gratuitous to assert, that the instinct or faculty of pointing was bestowed upon the pointer as a means of subsistence, since he has ever been dependant on man for food.

It is strongly argued, that all dogs have descended from one common stock, and that by difference in food, climate, and training, they have become what they are at present; nor is it more improbable that such is the fact, than that the human race are descended from one common parent; for dogs are not more dissimilar than the various tribes of men, who differ not only in outward form, but morally and intellectually, as much as dogs vary in size, shape, temper, and sagacity. Those animals which can be domesticated improve by acquaintance with man, as the wild fruits by cultivation. All wild dogs have some qualities in common; but their instincts are somewhat limited, or not called forth. It is only in its domesticated state that we find the various qualities which render the dog so useful a servant to man. Wild dogs are, in comparison with domesticated dogs, what savages (for wherever they have been found, savages bear some resemblance to each other, and are engaged in similar pursuits) are to civilized society. It is inconceivable that the mastiff, terrier, cur, and numberless other dogs besides the pointer, could ever have been in a wild state, as they do not seem to be possessed of any instincts or faculties that could enable them to subsist unattached to the human race.

The long received opinion that the lion, as the king of brutes, is possessed of the highest degree of physical courage, is exploded. The palm of courage is now awarded to the dog. Courage, however, in the common acceptation of the term, is not a characteristic trait of the pointer or setter, which are, perhaps, except the cur, the least courageous of the canine race. The dog is the only brute animal that prefers the society of man to that of its own species; and no dog is more affectionate or faithful to man than the pointer or the setter.

England is not less famous for its horses than for its sporting dogs. Our grey-hounds, fox-hounds, and harriers are unequalled, and that they are so results from the care that has been taken to keep each species distinct. All our pointers are, in some degree, of Spanish extraction; and such of them as have most Spanish blood in their veins are unquestionably the best. The Spanish pointer is about twenty-one inches in height. He has a large head, is heavily made, broad-chested, stout-limbed, with a large dew-lap; his eyes are full, and widely apart, and his nose is broad; his tail is straight, short, and thick, and his ears large, pendulous, and fine; he should have a round, and not a flat foot. When pointing, he stands on three legs, one of the fore legs being raised, and his face and tail are in a line with his back. This is his invariable position when he comes gradually upon the scent; but whenever, by running with the wind, or from any other circumstance, he comes suddenly upon game, he will stand in the most picturesque and sometimes indeed grotesque attitude, frequently with his body almost doubled. A pointer may be sometimes seen standing with all four feet collected together on the surface of a small stone on a wall when the birds are almost under him. A very old dog of this description, when fatigued with ranging and too enfeebled to maintain his point long in the natural position, will sit down on his haunches with his face towards the game, yet ever and anon turning his head wistfully to see whether the gun be approaching. Notwithstanding however the vaunted excellence of British pointers, the generality of them are not such as they ought to be. It is much to be lamented that the same care is not taken in the breeding of pointers and setters as of hounds. Scarcely two pointers are to be seen so much alike that a naturalist would pronounce them to belong to the same class of dogs, inasmuch as they are dissimilar in size, weight, and appearance. There are, properly speaking, but two classes, the Spaniard and the mongrel. Nearly all the pointers we see are, in fact, mongrels, although each may have more or less of the original Spanish blood. Such, however, is the force of nature that a dog having in him very little of the blood of the pointer may prove a very serviceable dog to the shooter. We frequently meet with very good dogs, dogs deemed by their owners first-rate, which bear little resemblance, in point of shape and appearance, to the true pointer. Some have the sharp nose of the fox, others the snubbed nose of the bull-dog; some are slenderly formed; some long-legged, others short-legged; some heavy-bodied, others light; in short, there is every possible diversity.

The attempt to lay down a written rule whereby to distinguish between a good and an indifferent pointer would be futile. How much of the blood of the pointer a dog has in him will be read in his countenance, rather than inferred from his general shape and appearance. There is an indescribable something in the countenance of a thorough-bred or nearly thorough-bred pointer, which a little habit of observation will enable the sportsman to detect with tolerable accuracy, so that he may judge of the capabilities of a dog, as a physiognomist will read at a glance a person's disposition and ability in his countenance. It is to the disciplined eye only that these all but infallible tokens are discernible.

The instinct of pointing, we apprehend, is an inextinguishable and indestructible principle in the blood of the pointer, which, however it may be mingled with inferior blood, will always, in some degree, manifest itself; and on this ground we build our theory that the further any dog is removed from the original Spanish pointer the worse the dog is; and, consequently, that all attempts to cross the pointer with any other blood must necessarily deteriorate the breed. The grey-hound is seldom or never crossed to give him additional fleetness, nor the hound to improve his nose; why then should the pointer be crossed with dogs which, in so far as the sports of the field are concerned, scarcely inherit one quality in common with him? Attempts, however, are constantly made to improve the pointer by a cross with the blood-hound, fox-hound, Newfoundland dog, or mastiff, sometimes with a view of improving his appearance, and bringing him to some fancied standard of perfection; but in reality inducing a deformity. One of these imaginary standards of perfection is, that to one part thorough Spanish blood, the pointer should have in him an eighth of the fox-hound, and a sixteenth of the blood-hound. A cross will sometimes produce dogs which are, to some eyes, the *beau idéal* of beauty; but however handsome such dogs may be, they will necessarily possess some quality not belonging to the pointer; for instance, a cross with the hound gives the propensity to trace hares, if not to give tongue. A thorough-bred pointer carries his head well up when ranging; he will not give tongue, nor has he much desire to chase footed game. The hound pointer may be sometimes detected by his coarse ears, by his tail being curled upwards, and being carried high, or by his rough coat. An occasional cross with the mastiff or Newfoundland dog is said to increase the fineness of nose, but it is converting the pointer into a mere retriever. The pointer, as we before observed, is naturally cowardly, as compared with other dogs; therefore, whenever a pointer is ferocious or courageous, it may be inferred that the blood of some of the larger or stronger dogs runs in his veins. Another and the main source of the unsightliness of sporting dogs is the allowing an indiscriminate intercourse between pointers and setters. Good dogs may be thus obtained sometimes, but they are invariably misshapen; they have generally the head and brush tail of the setter, with the body of the pointer, and their coats are not sleek, and instead of standing at their point, they will crouch. When the sire is nearly thorough-bred, dogs of a superior description, but certainly not the best dogs, are sometimes produced by the Newfoundland or some other bitch not strictly a pointer. We are not willing to allow that the pointer is improved in any quality that renders him valuable to the sportsman, by a cross with the hound or any other sort of dog; though we cannot deny that the setter is materially improved in appearance by a cross with the Newfoundland dog, but what it gains in appearance, it loses in other respects.

Breeding mongrels, especially crossing with hounds, has given the gamekeepers and dog-breakers an infinity of trouble which might have been avoided by keeping the blood pure. The best pointer is the offspring of a pointer-bitch by a pointer-dog; such a dog is nearly broken by nature. The Spanish pointer seldom requires the whip; the hound pointer has never enough of it. One of the main sources of the sportsman's pleasure is to see the dogs point well. A deal is said about this and that dog being remarkably fine-looking; the only time to appreciate the beauty of a dog is when he is ranging and pointing; then let the sportsman compare the real pointer with the spurious one.

Courage[1] is another attribute of the pointer; a high-couraged pointer will continue ranging till he has not, as the saying is, a leg to stand upon, even though he should not meet with game.

The usual price paid for breaking a dog is from two to five guineas. The breaker runs the dogs in spring, and again in August, but without the gun; this, followed by a week's shooting in September, renders their education complete, but unless they have sufficient practice afterwards, the initiatory lessons will soon be forgotten. Young dogs will learn more in six successive days, than in six weeks, if taken out only at the rate of one day per week. The dog-breaker should be a person of discriminating judgment, and possessed of a good temper; and the art of winning, not by brute force, but by judicious management, an ascendancy over the dogs entrusted to his care. Breaking dogs, when many young ones are taken out together, is a very difficult and tiresome task. One or more old staunch dogs are usually allowed to accompany the young ones, to induce them to back. A dog pointing is conscious of the presence of game. A dog which backs another is not aware of the proximity of game at the time, otherwise than by inference. Whenever the dog in advance points, it is the breaker's duty to make all the rest that acknowledge the scent to point, and all that do not acknowledge the scent should be shewn the dog pointing, and be made to back, which is done by the breaker holding up his hand, and crying, in an under tone, "to-ho." The dogs are taught to fall the moment the game rises, or on the report of a gun. They should come in on hearing their names or the whistle, and should never be allowed to pass a fence before their master. The efficiency of the training which a dog has received may be conjectured from his manner of quartering his ground. He should range at a short distance in advance of the shooter, alternately to the right and left; and this should be taught rather by the motion of the hand than by the voice. An offence should never be overlooked if the dog seems conscious of it; but the breaker's knowledge of the disposition of the dog should be his guide in regulating the punishment. Some dogs will not bear the whip, or even rating, but require encouragment and good words on all occasions. When it is necessary to flog a headstrong dog, it should be done severely, the blows falling on the side, from the shoulder to the flank. The lash or switch with which the dog is punished, should not be made to lap round the body, nor should the dog be kicked. When the dog is in fault, and is very eager in pursuing the sport, no punishment that will be longer remembered, can be administered, than making him crouch five or ten minutes. In common with other sports, shooting has a vocabulary of its own. We have elsewhere given a list of some of the words made use of by the breakers and sportsmen to the dogs, which we transcribe, many of them being anything but euphonious to the unaccustomed ear. "*To-ho* spoken in an under tone, when the dog is ranging, is a warning to him that he is close upon game, and is a direction to him to stand. There is no necessity for using it to a dog that knows his business. Spoken in a peremptory manner, it is used to make the dog crouch when he has flushed game, or been otherwise in fault. *Down-charge*, or *down-to-charge*, is used to make the dog, whether it be near or at a distance, to crouch when the shooter charges, that the dog may not flush game when the shooter is unprepared. When the dog will not crouch, but continues beating, the leg-strap may be put on. *Take-heed*, and *be-careful*, are used when the dog ranges over ground where it is customary to find birds. *Take-heed*, is a word of correction; *be-careful*, of encouragement. The former is used by way of caution or notice to prevent the dog flushing birds by running over the ground too fast; the latter is likewise a caution, but used when the dog beats slowly or carelessly. *'Ware fence* is used to prevent dogs passing a fence before the gun. The dog should never, on any account, leave an enclosure until its master has left it. *'Ware*, or *beware*, is used to rate a dog for giving chase to a hare, birds, or cattle, pointing larks, or approaching too near the heels of a horse. *Seek*, is a direction to the dog to look for a dead or wounded bird, hare, or rabbit. *Dead* is used to make a dog relinquish his hold of dead or wounded game. The dog should retain possession of wounded game until it is taken from him; for should he suffer a bird that is only slightly wounded to disengage itself from his grasp, another *seek* becomes necessary, and the bird is either lost, or despoiled of its plumage by the catching and re-catching. Some dogs are taught to bring the game to their master. The breaker should teach the dog, in all cases, to retain game until it is taken from him, or until he hear the word *dead*, when he should instantly drop it. The dog should be punished if he break the skin with his teeth."[2]

The most useful dogs are those which are best broken. As much depends on the breaking as the breed of a dog. Dogs should be constantly shot over during the season by a successful shot, and exercised during the shooting recess, by some person who understands well the management of them, otherwise they will fall off in value. The half-bred ones will become unmanageable, and even the thorough-bred ones will acquire disorderly habits.

We look upon the setter to be an inferior kind of pointer, perhaps originally a cross between the pointer and the spaniel, or some such dog as the Newfoundland, for it has some qualities in common with each. The pointer has the finer nose, and is more staunch than the setter. Pointers are averse to water; setters delight in it; hence the advantage of the latter on marshes to the snipe shooter. The setter will face briars and gorse bushes better than the pointer, which is in this respect a tender dog; and for this reason the setter is preferred to the pointer for cover shooting. Besides, his being not so staunch as the pointer is an additional advantage in heavy covers. The sportsman who shoots over well-broken pointers, frequently passes game in the woods, while the pointers, which are not seen by him, are at their point; the setter, being more impatient to run in, affords the shooter many shots in cover, which the overstaunch pointer would not. The pointer is always to be preferred on open grounds. In hot weather the pointer will endure more fatigue than the setter.

The Spaniel.

The Spaniel or Cock Dog. The spaniel is the best dog for beating covers, provided he can be kept near the gun. He is generally expected to give tongue when game is flushed; some spaniels will give notice of game before it springs, which may be very well where wood-cocks only are expected to be found. Wood-cock and pheasant shooting are usually combined; where covers are limited, pheasant shooting cannot be conducted too quietly. Wherever the underwood is so thick that the shooter cannot keep his eye on the dogs, spaniels are to be preferred to pointers or setters, whatever species of game the shooter may be in pursuit of. If spaniels cannot be kept near the shooter, they are the worst dogs he can employ.

Retrievers.

Retrievers. The business of the retriever is to find lost birds. Newfoundland dogs are the best for the purpose. They should have a remarkably fine sense of smelling, or they will be of little use in tracing a wounded pheasant, or other game, through a thick cover, where many birds have been running about. A good retriever will follow the bird on whose track he is first put, as a blood-hound will that of a human being or deer. They should be taught to bring their game, or in many instances their finding a wounded bird would be of no advantage to the shooter.

---

[1] Courage, as applied to the pointer, signifies a willingness and determination to range; it is an union of the qualities known by the terms mettle and bottom, as applied to horses.

[2] The Oakleigh Shooting Code. London, Ridgways. Third Edition.

We proceed next to give some description of the art of shooting game, in the course of which we shall endeavour to confine our obseravtions to such of the habits and peculiarities of the birds and quadrupeds under notice, as it is essential the shooter should be made acquainted with, and at the same time to detail the means of proceeding most likely to ensure success in the pursuit of them.

The Partridge.
Plate CCCCLXI.

The Partridge. We commence with the partridge, as shooting that bird is generally the young shooter's first lesson at game, although in the order of the season grouse shooting takes precedence. Partridge shooting commences on the first of September, and ends on the first of February.

The habits of the partridge at different seasons should be closely understood and studied by the shooter, that he may be able, with a tolerable degree of certainty, to find them at any given time. In the early part of the season, they will be found, just before sunrise, running to a brook, a spring, or marsh, to drink; from which place they almost immediately fly to some field where they can find abundance of insects, or else to the nearest corn-field or stubble-field, where they will remain, according to the state of the weather, or other circumstances, until nine or ten o'clock, when they go to bask. The basking place is commonly on a sandy bank-side facing the sun, where the whole covey sits huddled together for several hours. About four or five o'clock, they return to the stubbles to feed, and about six or seven they go to their jucking-place, a place of rest for the night, which is mostly in aftermath, or in a rough pasture field, where they remain huddled together until morning. Such are their habits during the early part of the season; but their times of feeding and basking varies much with the length of the days. While the corn is standing, unless the weather be very fine or very wet, partridges will often remain in it all day; when fine, they bask on the outskirts; when wet, they run to some bare place in a sheltered situation, where they will be found crowded together as if basking, for they seldom remain long in corn or grass when it is wet. Birds lie best on a hot day. They are wildest on a damp or boisterous day.

The usual way of proceeding in search of partridges in September is, to try the stubbles first, and next the potato and turnip field. Birds frequently bask amongst potatoes or turnips, especially when those fields are contiguous to a stubble-field. The best partridge shooting is obtained in potato and turnip fields. It not unfrequently happens that potatoes or turnips are grown on a headland in a corn field; in that case the headland will be a favourite resort of birds.

After the middle of October it is ever uncertain where birds will be found; the stubbles having been pretty well gleaned, birds do not remain in them so long as in the early part of the season. When disturbed at this time they will sometimes take shelter in woods, when they are flushed one by one. The best shots that can be obtained at partridges in winter, are when the birds are driven into woods.

When a covey separates, the shooter will generally be able to kill many birds, but late in the season it is seldom that the covey can be broken. In November and December the shooter must not expect to have his birds pointed, but must remain content with firing at long distances. We transcribe the following observations on dispersing coveys: "In the early part of the season, when the shooter *breaks* a covey, he should proceed without loss of time in search of the dispersed birds, for the parent birds begin to call almost immediately on their alighting, the young ones answer, and in less than half an hour, if not prevented by the presence of the shooter and his dogs, the whole covey will be re-assembled, probably in security in some snug corner, where the shooter least thinks of looking for them. As the season advances birds are longer in re-assembling after being dispersed. It is necessary to beat very closely for dispersed birds, as they do not stir for some time after alighting, on which account dogs cannot wind them until nearly upon them, especially as they resort to the roughest places when dispersed. Birds dispersed afford the primest sport. The pointing is often beautiful, the bird being generally in a patch of rushes, or tuft of grass or fern, and close to the dog. When a bird has been running about some time, dogs easily come upon the scent of it; but when it has not stirred since alighting, and has perhaps crept into a drain, or run into a hedge-bottom, or the sedgy side of a ditch, no dog can wind it until close upon it, and the very best dogs will sometimes flush a single bird. In the month of October, and afterwards, the shooter will find it difficult to approach within gun-shot of a covey, nor can he disperse them, except by firing at them when he chances to come close upon them. Should he then be so fortunate as to disperse a covey, he may follow them leisurly, for they will then lie several hours in their lurking place, which is chosen with much tact, as a patch of rushes, a gorse bush, a holly bush, the bottom of a double bank fence, or a coppice or wood. The length of time that will transpire before a dispersed covey will re-assemble, depends, too, on the time of the day, and state of the weather. In hot weather, they will lie still for several hours. A covey dispersed early in the morning, or late at night, will soon re-assemble. A covey dispersed between the hours of ten and two, will be some time in re-assembling. A covey found in the morning in a stubble field, and dispersed, will next assemble near the basking place. A covey dispersed after two o'clock, will next assemble in the stubble field at feeding time. A covey disturbed and dispersed late in the afternoon, or evening, will next re-assemble near the jucking-place. A covey being disturbed on or near to their jucking-place, will seek a fresh one, perhaps about two fields distant; and if often disturbed at night on their jucking-place, they will seek another stubble field to feed in, and change their quarters altogether. The most certain method of driving partridges from a farm, is to disturb them night after night at their jucking-place, which is usually in a meadow, adjoining to a corn field, where the aftermath is suffered to grow, or in a field rough with rushes, fern, thistles, or heather. When a covey is dispersed on a dry hot day, it is necessary to search much longer, and beat closer, for the dispersed birds, than when the day is cool, and the ground moist. A dog should be only slightly rated for flushing a bird on a hot day."[1]

The number of birds in a covey varies much, perhaps the average may be from ten to fifteen. In some years, when the coveys are large after a fine hatching season, it is not uncommon to see upwards of twenty birds in a covey; and sometimes after a wet season, ten birds may be deemed a fair covey. Birds are always most numerous after a dry summer. When there are thunder-storms about midsummer, great numbers of young birds are drowned. The young birds have many enemies besides the elements, such as cats, young dogs, hawks, foxes, and vermin of different descriptions. When the eggs are taken, or the young birds destroyed soon after leaving the shell, there will be a second hatch. Sportsmen often meet with second hatches in September, when the old birds rise screaming, and generally alight within fifty yards, as if to induce the young birds to follow. In that case the fair sportsman will not fire at the old birds, but will call in his dogs and leave the ground. At such times he should look well after the young dogs, as, when they see the birds running, they are apt to snap up such of them as cannot get out of the way. The very young birds are called cheepers, from their uttering a scream as they rise. Full grown birds never scream as they rise, except when the young ones are helpless, nor do young birds after they are large enough for the table.

---

[1] The Oakleigh Shooting Code.

The cock partridge is distinguished from the hen by the brown feathers which form a crescent, or horse-shoe, as it is sometimes called, on the breast.

The pointer is decidedly the best dog for partridge shooting. Markers and retrievers will be of much service to the shooter whose object is to kill a great quantity of birds, rather than to enjoy the sport.

T asant. e CLXI.

The Pheasant. The pheasant is the most splendidly arrayed of undomesticated British birds. It is deservedly in high request amongst sportsmen, and it claims the first attention of the game-preserver. The numberless plantations and coppices which are everywhere springing up, afford yearly additional shelter. The pheasant prefers woods of oak and beech, that it may feed on the acorns and mast. The fine old woods consisting of these trees may perhaps be diminishing, but they are more than replaced by plantations of larch or other quick-growing trees. Pheasants generally choose the larch or spruce-fir to roost in, and plantations of this description, if near corn, turnip, or potato fields, afford sufficient cover for them. They are, in many counties, allowed to become so numerous, as to do serious mischief to the labours of husbandry.

During August and the early part of September, pheasants will remain nearly all day in potato and corn fields. Pheasant shooting commences on the first of October, and ends on the first of February. In October, the shooter usually meets with them in potato and turnip fields, deep stubbles and rushy fields near covers, but especially under hedges, holly trees, or in coppices near to covers. In such situations they will suffer the shooter to approach very near to them; they are generally pointed by the dogs, and, a large majority of them being young birds, are easily killed; but in that month the trees are so full of foliage, and the briars and brushwood are so annoying, that it is seldom possible to beat the woods with any degree of pleasure, for not only are they almost impervious, but the pheasants are seldom seen when they rise, or if seen and shot, are very frequently lost, or not found without considerable loss of time. It is in November, when the birds have moulted, and when the leaves have fallen, and the brambles are decaying, and the paths in the woods are beginning to be worn, that pheasant shooting is in perfection. The birds are then full grown, and also better fed than later in the season.

It is not usual to kill the hens wherever pheasants are strictly preserved; but it is necessary to kill the cocks where they are too numerous. Pheasants do not pair, and as it is better that there should be but few cocks, the shooter's being able to single them out and kill them, tends ultimately to the increase, and not to the diminution of the number of birds in cover. At the commencement of the season the shooter will frequently flush a nide of pheasants, but in the after part of the season he will oftener find solitary birds. Pheasants will occasionally wander a considerable distance from the wood to which they belong, especially during winter, in search of food, and in wet and foggy weather. The pheasant basks at the root of a tree, or under a hedge, in the same manner as the partridge, but each bird nestles itself separately. Pheasants approach nearer to domesticated poultry than any other kind of game. Pheasant shooting is most destructive where the plantations are not more than forty yards wide; when the shooters remain on the outside, while the beaters and dogs rouse the game within. The pheasant shooter does not expect set shots; his object is to cause the birds to rise as near to him as he can. Having no notice of them, he should ever be on the alert for snap shots.

A short double-barrelled fowling-piece, of wide bore, is preferable to a long one. The shot should be large, and it is well to use plenty of it. A close-shooting gun is not to be recommended to the pheasant shooter. The birds should rarely be fired at in cover when more than thirty yards from the gun, or they will escape wounded in the underwood. They are generally brought down within twenty yards from the gun. Pheasants are most plentiful in Norfolk, Suffolk, and some of the adjoining counties. There are some in every county in England, and in most of the counties in Scotland. A perfect bird has a white annular space on the neck, but this mark is often wanting.

The pheasant makes a considerable noise when rising, sufficiently so to unnerve the young and over-anxious shooter. The bird should be allowed to rise clear of the bushes, and to its full height, before the shooter fires at it, or it is probable he will fire too low; and again, the short fan-like feathers on either side of the tail appear, as the bird is rising, to be part of the bird, making the body seem longer and larger than it really is; and this circumstance, together with the rapidity of the movement of the bird when rising, is the cause of the shooter firing too low. The aim should always be at the head, unless the bird is crossing, and then well forward. Firing too soon, lest the bird should be out of reach, is a very common error, particularly with young sportsmen.

For reasons which we have before adverted to, the setter, or cock-dog, is to be preferred to the pointer for pheasant shooting. Pheasants will sometimes lie very close, so that it is with great difficulty they can be made to rise; therefore dogs that will dash into the thicket are most useful. Beaters and retrievers are indispensable to the pheasant shooter.

The Hare

The Hare. The shooter seldom beats purposely for hares. Birds are mainly the object of his pursuit. He chooses his ground, and regulates the charge of his fowling-piece with reference to the birds he expects to meet with. Hares are started casually, as it were, while he is in quest of birds. Leveret shooting often commences with grouse shooting, on the 12th of August, though it is not uncommon, nor is it considered unfair, to kill leverets during the summer months. Hares are not in season until September. The shooter should desist from killing them in February, but he is not prevented from killing them at any season, by any legislative enactment, if he have taken out a game certificate. It is the prescriptive law of the chase, held sacred by sportsmen, that prevents him.

In September, hares lie close, in hedges, in woods, or in growing corn, and are somewhat difficult to be found. They are scared from the woods by the leaves falling in autumn, and they are then found, particularly after stormy weather, in pasture and stubble fields. Dogs will frequently point them. In November and December, they are often seen on their seats, or forms, as they are sometimes called, by the shooter keeping his eyes on the ground about eight or ten yards from him. It is usual, however, to allow the hare a chance of escape, by starting her before firing at her; it is accounted unsportsmanlike to kill puss on her seat. In January, hares are found on fallows, marshes, or in pastures, or in or near to gardens.

The shooter should fire well forward at a hare, and not too high. He should not fire at a long distance, as the probability of his wounding her would be greater than that of killing her. If running direct from him, a hare should not be fired at, unless within twenty-five paces from the gun, or she will often run off, though severely wounded in the hind-quarters. A beater will render essential service to the shooter in quest of hares, in the early part of the season; the beater walks on the contrary side of the hedge to the shooter, and a few yards in advance, so that the hare, to avoid the former, jumps out on the side of the latter. When beating hedges in the vicinity of covers, the shooter should take care to place himself on that side nearest the covers. When shooting at the edge of a cover, if the hare fired at is not quite deprived of the use of her legs, it would be advisable to fire again immediately, for should she crawl through the hedge, the chances would be against her being retrieved.

The Rabbit.

The Rabbit. Rabbits are alternately deemed game and vermin. They are sometimes shot for sport, sometimes for profit, and sometimes on account of the mischief they do to trees and other vegetation. They sometimes seat themselves all day long, after the manner of hares, but more frequently they remain the greater portion of the day in their burrows. As they are shy of approach, and run under ground on the least alarm, the shooter frequently finds it expedient to hide himself at a little distance from the warren, and wait until they come out. Where rabbits are numerous, as in most warrens they are, some will be continually playing within a few yards of the entrance of the burrows, and when found in such situations (for they are very tenacious of life), they should be struck very hard, or they will contrive to crawl, or rather roll into their earths, before the shooter can pick them up. It is astonishing what efforts they will make to escape, though three legs be broken, when near to the entrance of a burrow. It is of little use firing at them when they are more than twenty paces distant from the gun. Rabbits afford more what are termed snap-shots than any other game, as they are mostly found in or near to plantations, or amongst brambles, hollies, gorse or deep fern, in places of extreme difficulty. It requires a quick eye and steady hand to stop a rabbit running across furrows, or over uneven ground. Rabbits for sale, or when destroyed as vermin, are oftener taken by means of ferrets and nets, than killed by the gun. A short gun, having a large bore, and charged heavily with powder, and a small quantity of No. 4 shot, is best for rabbit shooting. It would be well that a companion or servant should lead a dog in a slip—a terrier is as good as any—to be loosed the moment the gun is fired; thus many a rabbit will be secured, that would else have run into its hole. When earthed, it frequently happens that a rabbit is not able to crawl more than three or four feet deep from the surface, where it dies, when it may be recovered by thrusting a bramble down the hole, and twisting it so as to entangle the rabbit; but a more certain method, if the rabbit is not too far down, is to screw the worm of the ramrod into its body, and so drag it out, as a cartridge is drawn from the barrel of a gun. The best time for rabbit shooting is in the evening, or during sunshine just after a shower, when great numbers of the rabbits venture from their burrows.

The Busta

The Bustard. The bustard is a rare but valuable acquisition to the game-bag. As it cannot be approached unless the shooter takes advantage of some adventitious circumstances, it is seldom an object of pursuit to the sportsman. Bustard shooting commences on the first of September, and ends on the first of March.

The Sn

The Snipe. There are three kinds of snipes, viz. the solitary or double snipe, the full or whole snipe, and the jack or half snipe. The last is considered to be scarcely worth powder and shot; it is the full snipe which principally engages the shooter's attention. We have before given directions for shooting this bird. "The common or full snipe is a shy bird when in company, but when alone will allow the shooter to approach within a dozen paces of it before it springs. When it does spring, however, it moves with a velocity that defies the epithet *slow!* It is best to shoot as soon as possible. The shooter will bring down a snipe with much less difficulty at from fifteen to twenty paces than at any other distance. The aim is thus taken before the bird begins to make its cross flights, and before it has attained its full speed. The irregularity of its flight is of little consequence during the first and second twirling, before the bird is safely on the wing, since its flight is then comparatively tardy. But let the snipe fly ten yards from whence it sprang,—let it be, for instance, twenty-five paces distant from the gun, it is then at the top of its speed, and in the very midst of its sidelong, elliptical gyrations, and more than a match for the majority of shooters, especially if the day be windy. A snipe killed at fifteen or twenty paces distance, with No. 7 shot, the aim being true, will be struck by twenty or thirty pellets, but the chances are more than twenty to one against the aim being true. The snipe, when struck, is generally three or four inches from the centre of the cone which the shot forms as it flies, which is very different from being in the exact centre. A section of the body of a snipe does not present a surface as large as that of a penny-piece. If any person will fire at a target at fifteen yards distance, he will find that a snipe would not be cut to pieces even at that distance, unless it chanced to be precisely in the centre of the charge as thrown. When speaking of a snipe presenting no larger a surface as a mark than a penny-piece, we of course mean a snipe flying directly from the shooter. It would be imprudent to shoot at a snipe flying across at less than twenty-five paces distance, as it then presents more than double the surface of one going straight from the shooter. Thirty paces is the distance we should prefer for a cross or oblique shot. At thirty, or even at twenty-five yards, unless the barrel throws shot remarkably close, there are interstices in the charge as thrown, in which a snipe would escape untouched. Provided the flight of a snipe were equally steady at all distances, and that in every instance the shooter could choose his own distance, a snipe would have the least chance for its life at twenty yards. But there are two points to be attended to in determining the proper distance—the flight of the bird, and the manner in which the shot is thrown. In snipe-shooting the latter is subservient to the former. The few full snipes occasionally found on heathery and rush-clad hills, as well as in the enclosed grounds, lie much more dispersed than the gregarious birds of the marsh. Hence those found on the uplands are easy, and those on the fens difficult of approach. It is, however, the same description of bird that is found in both situations." When the shooter uses wire cartridges, which, by the bye, are not precisely calculated for snipe-shooting, it would be prudent to allow the bird to move to a considerable distance before firing. It is scarcely necessary to add, that the shot used for snipe-shooting should be very small. When several snipes rise together, they are styled a wisp.

T
W dcock.

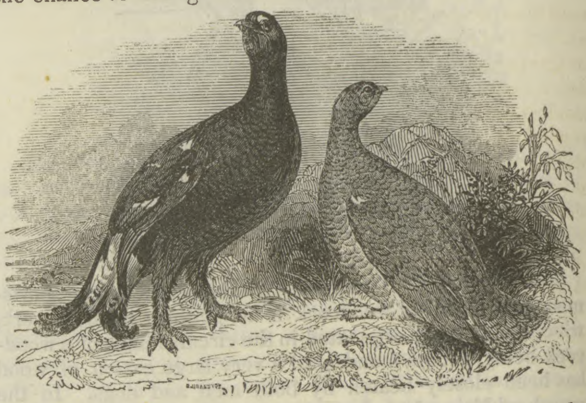
The Woodcock. There is a proverb current among sportsmen, that to kill a woodcock is to perform a day's work, which doubtlessly originated in the circumstance of a woodcock being seldom found until a very large extent of wood has been closely beaten by both men and dogs. In the month of November, however, when woodcocks are most abundant, it would not be a difficult task, according to that standard of labour, to do the work of a week in a day, in any noted cover, for every cover frequented by woodcocks, (or cocks as they are called in the sportsman's nomenclature), acquires a notoriety which it seldom loses, since any wood well frequented with cocks one year, has generally a fair supply the next. But whether the same cocks that frequent a wood this year, return the next, with their offspring, or whether an entirely new set of occupants take possession, we leave the ornithologist to decide. A certain description of woods are seldom known to fail of woodcocks during the winter months; these woods or plantations are such as are swampy, or have a stream of water running through them, or woods abounding in springs, or where, from the nature of the ground, or want of draining, the top water encourages the growth of moss. The woodcock is rarely found where moss is not abundant. During a frost, cocks are found near fresh water springs; at other times, they are most commonly flushed in the open glades of the densest woods, or rather in those parts of the woods not choked up at the bottom with fern, rushes, or brambles, but where they can freely run about, and in those parts where willows, osiers, hazel-trees, or crate-wood is plentiful. In such places it will readily be ascertained whether there are cocks or not, by the borings in the moss or dead leaves, and by the droppings. Should the cock not be brought down, it will not fly far after being fired at; it should, when practicable, be marked down, as by this means several successive shots may be obtained at it when the gun is unsuccessful. It is seldom that the skilful shooter springs a cock which he does not eventually kill. The difficulty of woodcock shooting arises, for the most part, from the birds springing in the thickest part of woods, and contriving to wing their flight through the trees, in such a manner as to baffle the sportsman's aim. After being fired at in a wood, cocks will frequently alight amongst hedge-rows on the outskirts, especially under a hedge running close to and parallel with a water-course, when they are easily killed, as they will not rise until the shooter is close upon them; and their flight is not difficult to master when there are no trees to obstruct the aim. Woodcocks are found in October on moors, and in covers near the sea. About the last week in October they find their way to the inland covers, where they remain during the early part of the winter, and they are sometimes found there again in March. A sharp frost, or a dense fog, at the end of October or beginning of November, is usually the shooter's first intimation of the arrival of cocks; and if he is ambitious of the fame of killing them, he must fag hard during the month of November, or it is probable that his return for the season of the numbers bagged will not be satisfactory. November is unquestionably the best month for cock shooting.

The Red Grouse.
Plate CCCCLXI.

The Red Grouse. Grouse shooting commences on the 12th of August. We have already alluded to the vast extent of the northern moors. The number of birds killed on the opening day, on some parts, is very great. It is not uncommon for an experienced and skilful shooter, on the best moors, to bag fifty brace on the 12th of August. What may be termed a good day's sport, differs much on different moors. On well-preserved moors, the average may be from ten to twenty brace. On subscription moors, the shooter should not be dissatisfied if he has the opportunity of killing from three to five brace per day, during the first week of the season, though this would be deemed a low average for the Scottish moors. After the first week, few sportsmen, except those residing in the immediate neighbourhood of the hills, ever trouble the moor game.

Many causes contribute to the popularity of grouse shooting, amongst which may be enumerated the following. It commences during the parliamentary recess, and long vacation—the legislator's, lawyer's, and collegian's holiday; and it is no wonder that after being cooped up all summer, these, or any other classes of society, should seek relaxation in the sports of the field. August is the season when every one, from the peer to the shopkeeper, who can afford the indulgence, either rusticates or travels. In that month the casual tourist, the laker, and the angler, are often in the North, when the temptation to draw a trigger is irresistible. Grouse shooting fascinates the young shooter more than any other kind of sport, inasmuch as the season commences with it. The opening day is looked forward to with pleasing anticipation all summer. To the more practised sportsman, grouse shooting recommends itself by reason of the superiority of the sport over every other kind of shooting. Partridge shooting is a comparatively tame and uninteresting amusement. Partridge shooting, as compared with grouse shooting, may be termed domestic sporting. To the majority of sportsmen, a grouse shooting excursion only occurs once a year, and then lasts only a few days. The sport therefore seldom palls; but during the long interval of time that elapses between each, the coming season is ever looked forward to with additional interest. Grouse shooting is, in many respects, a source of greater expenditure to the sportsman: it requires more preparation, and is attended with more difficulties than any other kind of shooting; but these circumstances, whatever some people may imagine to the contrary, so far from detracting from, serve to enhance the enjoyment of the sport; for we are apt to estimate whatever is obtained with difficulty and expense at a higher rate than what is gratuitously afforded us. To the lover of the romantic and the picturesque, grouse shooting has attractions of the highest order. It is the sport of all others peculiarly British: the partridge, the pheasant, the black-cock, are widely dispersed over other countries; but the red grouse is only found in the British Islands.

There are seldom more than a dozen grouse in a brood; rarely indeed so many. Towards the end of autumn, the broods congregate together, and are seldom seen afterwards until pairing time in January or February, except in great numbers. Broods thus associated are termed packs. When it happens that the birds are well grown at the opening of the season, and much fired at in August, they will pack before September. When there is fine weather in August, grouse, until the broods are packed, will suffer the shooter to approach very near to them before they rise. In wet or windy weather they are wild. Very few grouse are killed by the sportsman after August; they are then scarcely approachable. Grouse delight in tall young heather, when there are plenty of bare places or pads or tracks. Hares also, and cocks, and we may perhaps add, pheasants, in their respective covers, delight in those parts where they can run about freely. The brow of a hill is more likely ground than either extreme heights or valleys, or flats. Solitary birds lie better than broods. When birds are wild, the shooter should follow an individual rather than a brood. It is well understood by sportsmen, that the fewer birds there are in a brood, nide, or covey, the better will they lie. Grouse bask on the sunny hill-side, oftentimes under a rock, or in a stone pit, during the middle of the day, at which time the task of ranging for them is toilsome in the extreme. Grouse shooters should be accompanied by a guide and markkers. The former is indispensable to a person not intimately acquainted with every turn and knoll, during the mist that nine mornings out of ten envelopes the hills in August. It is inconceivable how completely bewildered a person who fancies he is acquainted with every inch of ground may be when surrounded by the haze. Neither sun, moon, nor stars are visible; nor is there a fence, road, or building to direct him. A stone pit, or mountain rill, are often the only objects that present themselves, except the interminable heather. The distant hills that would else be his guides, are shut out from his view, which does not extend beyond the range of his fowling-piece. At such times it requires no ordinary precaution to prevent losing young dogs, which can scarcely be prevented running off when a gun is fired in the distance. During the continuance of the mist, which generally disappears about eight o'clock, markers can be of but little use, except that they may be employed in carrying a basket, extra guns and shot, or leading dogs, of which it is well to have a change. No dog can range two days successively for grouse. Pointers, for reasons we have before given, are preferable to setters, or any other kind of dogs, for grouse shooting. Grouse shooters should separate and range singly; they should have no noisy attendants; nor any dogs that require rating. The sport cannot be carried on too quietly. If the shooter throws off before eight o'clock, which it is not prudent to do unless there are many guns on the moors or foul weather is expected in the afternoon, he should run only one dog as long as the heather is wet, afterwards two, and in the afternoon three dogs. In wet weather one dog is quite sufficient. If hot weather, we advise rest from eleven to two. If the shooter have not exhausted himself during the middle of the day he will best fill his bag in the afternoon; he may not, indeed, then find so many, but those he does find will be dispersed birds that will almost lie to be trodden on. An old shooter thus on a dry afternoon following a wet morning will sometimes load himself or his attendant, after the less experienced have left the moor disgusted, with scarcely a bird in their possession. Shooters are generally recommended to carry as heavy a gun as they can conveniently manage on the moors. It should be borne in mind that the heaviest gun will do most execution; but none except those accustomed to such exercise, can carry a heavy gun with comfort all day long, exposed to an autumnal sun. We would therefore not recommend barrels more than thirty inches long, nor of a larger guage than sixteen, on account of the excessive heat of the weather at this season. As the sportsman, in grouse shooting, has ever an opportunity of choosing his own distance when birds rise near to him, he will be more certain of killing if he let the birds fly twenty-five yards from him before he fires the first barrel, when, if he have both barrels cocked, he will have ample time to throw in the reserve barrel while the birds are within reasonable distance. In nothing is the superiority of the detonating over the flint lock more apparent than in its allowing the shooter to fire the second so soon after the first barrel. We suspect that the habit of taking the gun from the shoulder after the first barrel was fired, originated in the necessity of waiting until the smoke from the pan was blown away, which nuisance no longer exists. A person who is a decidedly bad shot should not use the cartridge in the first barrel, as the loose charge gives a larger circle at a short distance, and consequently increases the chance of killing.



The Blackcock. Black game shooting commences on the 20th of August, and ends, with red grouse shooting, on the 10th of December. Black game frequent moors covered with heather, but they are as often found in rushy fields, or even in stubbles adjoining to moors. They are not met with at any great altitude, but confine themselves chiefly to the lower hills, or the base of the loftier mountains. They are seldom found, except where there are plantations or forests of fir trees. Black game do not frequent the central parts of large wastes so much as those parts bordering on inclosed lands. Red grouse recede where civilization progresses; and they are consequently in a fair way, at no very distant period, of being banished from England. As a vast extent of heath-land is not requisite for black game, there is no room to fear their extinction for some centuries to come. Although not so numerous as red grouse, they are more widely scattered over England. Even in the south of England there is cover congenial to them. Should both black and red game become extinct in England, the hills of Scotland will long afford shelter to each. With the exception of the pheasant, black game is the only species of game not yearly diminishing in number in Britain. A full-grown blackcock weighs the same as a fine pheasant cock, about three pounds and a half. The female, which is called the grey-hen, and ought never to be fired at, is much smaller. Black game shooting on moors resembles red grouse shooting, and in the woods, pheasant shooting. The black cock is a magnificent bird, and an old one is ever deemed a valuable addition to the contents of the game bag. Black game have increased very considerably in England during the last few years, still they are much more abundant in Scotland. Sweden is perhaps the country best suited to them.

The Capercailzie. Similar to the blackcock, in many respects, is the capercailzie, or cock of the wood, once the native, and now the denizen of the Highland forests. The capercailzie cock weighs sixteen pounds. Speaking of this bird, as it exists in Sweden, Mr. Lloyd says,[1] "The favourite haunts of the capercali are extensive fir woods; in coppices or small cover he is seldom or never found. The principal food of the capercali, when in a state of nature, consists of the leaves of the Scotch fir; he very rarely, however, feeds upon those of the spruces; he also eats juniper berries, cranberries, blaeberries, and other berries common to the northern forests; and occasionally also, in the winter time, the buds of the birch, &c. The young capercali feed principally at first on ants, worms, insects, &c." It was the felling of the timber, aided, perhaps, by the cross-bow, which is not ill-adapted to the purpose, that exterminated this primeval habitant of the old Caledonian forests. Some years since an attempt was made to re-introduce this bird to its ancient haunts in Scotland, but without success. "It is a pity," continues Mr. Lloyd, "that attempts are not made once more to introduce the capercali into the United Kingdom, for, if the experiment was undertaken with judgment, it would most probably be attended with success; the climate, soil, &c. in Scotland, at least, not being very disimilar, in many respects, to the south of Sweden. In Scotland, besides, independently of the natural forests, there are now considerable tracks of land planted with pines, from which trees, when the ground is covered with snow, those birds obtain nearly the whole of their sustenance." Since this was written, several brace of these birds have been sent over from Sweden; and on the estates of the Marquis of Breadalbane the experiment of localising them is in course of trial. We believe they were procured by Mr. Lloyd himself, and under his auspices, from his knowledge of the habits of the bird, we doubt not that the cock of the wood will become permanently established in the Highlands. It may be inferred that the same description of country (the heaths and forests being on a more extended scale,) which suits the blackcock, would likewise suit the capercailzie, since, as Mr. Lloyd observers, "the capercali occasionally breed with the black game; the produce of which partake of the leading characteristics of both species. Their size and colour, however, greatly depend upon whether the connexion was between the capercali cock and the grey hen, or *vice versâ*." In winter, the male birds congregate in packs after the manner of black game. In Sweden the capercailzie is usually shot with the rifle.

Th
Pta igan.
Pla
CCC XI.

The Ptarmigan. We have now for some time traversed, with the reader, the highest hills that are covered with heather, but there are heights beyond. The poet says,

For Liberty! go seek
Earth's highest rocks and ocean's deepest caves!
Go where the eagle and the sea-snake dwell![2]

It may be admissible in poetry to give the highest cliffs to the king of birds, but zoology assigns a lower elevation to "the eagle's birth-place;" yes, you may ascend above the äerie of the eagle, where the croak of the raven is never heard, where the fox and the weazel but seldom disturb the lonely habitants. You may ascend until, in the glowing language of Mr. Mudie,[3] "you begin at last to feel alone, severed entirely from the world of society, of life, and of growth, and committed to the solitude of the ancient hills and immeasurable sky. The snow lies thick on the side of the summit, and even peers over the top, defying the utmost efforts of solstitial heat. There is no plant under your feet, save lichen on the rock, apparently as hard and as strong as that to which it adheres—it can hardly be said to grow—and moss in some crevice, undistinguishable from the dull and cold mud into which the storms of many winters have abraded the granite. You are above the reach of all sound from the inhabited parts of the country." And what do we find in this region of snow? "A few mottled pebbles, or at least what appear to be such, each about twice the size of your hand, lie at some distance, where the decomposed rock, and the rudiments of what may be called the most elevated mountain vegetation, just begin to ruffle the surface. By and by a cloud shadows the sun, the air blows chill as November, and a few drops fall, freezing or melting in their descent, you cannot well tell which. The mottled pebbles begin to move; you throw a stone at them to shew that you can move pebbles as well as the mountain. The stone hits beyond them; they run toward your feet, as if claiming your protection; they are birds, ptarmigan, the uppermost tenants of the island, whom not even winds, which could uproot forests, and frosts, which could all but congeal mercury, can drive from these their mountain haunts. It has often been observed, that of all the human inhabitants of the earth, the mountaineer, be his mountain ever so barren, is the last to quit; and the same holds true of the mountain bird." The same writer traces the different elevations at which various species of game is found, beginning with the pheasant, as the tenant of the lowermost woods; the partridge, of the plain; the blackcock, of the confines of cultivation; the grouse, of the lesser hills and mountain-side; and the ptarmigan, of the snow-crowned summits. He also adds, "in these birds we trace a sort of resemblance to the general colour of the places which they inhabit, though we know not well the cause of the colour in either case. The ptarmigan is mossy rock in summer, hoar frost in autumn, and snow in winter. Grouse are brown heather, black game are peat-bank and shingle, and partridges are clods and withered stalks all the year round." And we will add, the capercailzie is the black branch of the pine. A similar scale is applicable to the seasons at which these birds are hatched. Although, taking each species individually, we find the earliest birds in the warmest country and on the richest land: collectively, the order is reversed; the higher their location, the earlier do they arrive at their full growth. The ptarmigan is ready for the table before the period at which it may be legally shot, the twelfth of August. Descending the hill, we find the red grouse not three parts grown at that period. A little lower, and the scarcely-fledged black-cock rises almost helpless, on the twentieth of August. Lower still, on the fertile plain, the young partridge does not assume his grey mantle and purple crescent until long after the first of September. And in the warm woods the pheasant does not don his panoply of gold until the fall of the leaf.

Few are the sportsmen who climb the granite cliffs, and wade the winter snows in which ptarmigan delight to bury themselves. A ramble there, is a journey of curiosity or observation, rather than a sporting excursion. It is a pilgrimage to the loftiest Highland altitudes. The fowling-piece becomes converted into the palmer's staff; and the sportsman merges in the adventurer, the enthusiast, the worshipper of Nature!

(B. X.)

SHORE, a place which is washed by the sea, or by some large river.

Count Marsigli divides the sea-shore into three portions; the first of which is that tract of land which the sea just reaches in storms and high tides, but which it never covers; the second part of the shore is that which is covered in high tides and storms, but is dry at other times; and the third is the descent from this, which is always covered with water.

The first part is only a continuation of the continent, and suffers no alteration from the neighbourhood of the sea, except that it is rendered fit for the growth of some plants, and wholly unfit for that of others, by the saline steams and impregnations; and it is scarcely to be conceived by any but those who have observed it, how far on land the effects of the sea can reach, so as to make the earth proper for plants which will not grow without this influence; there being several plants frequently found upon high hills and dry places, at three, four, and more miles from the sea, which yet would not grow unless in the neighbourhood of it, nor will they ever be found elsewhere.

The second part or portion of the shore is much more affected by the sea than the former, being frequently washed and beaten by it. Its productions are rendered salt by the water, and it is covered with sand, or with the fragments of shells in the form of sand, and in some places with a tartarous matter deposited from the water. The colour of this whole extent of ground is usually dusky and dull, especially where there are rocks and stones covered with a slimy matter.

The third part of the shore is more affected by the sea than either of the others; and it is covered with an uniform crust of the true nature of the bottom of the sea, except that plants and animals have their residence in it, and the decayed parts of these alter it a little.

Shore, *Jane*, the celebrated mistress of Edward IV., was the wife of Matthew Shore, a goldsmith in Lombard-street, London. Historians represent her as extremely beautiful, remarkably cheerful, and of most uncommon generosity. The king, it is said, was no less captivated with her temper than with her person. She never made use of her influence to prejudice any person; and if ever she importuned him, it was in favour of the unfortunate. After the death of Edward, she attached herself to Lord Hastings; and when Richard III. cut off that nobleman as an obstacle to his ambitious schemes, Jane Shore was arrested as an accomplice, on the ridiculous accusation of witchcraft. This, however, terminated only in a public penance, excepting that Richard rifled her of all her little property; but whatever severity might have been exercised towards her, it appears that she was alive, though sufficiently wretched, under the reign of Henry VIII., when Sir Thomas More saw her, poor, old, and shrivelled, without the least trace of her former beauty. Mr. Rowe, in his tragedy of Jane Shore, has adopted the popular story related in the old historical ballad, of her perishing by hunger in a place where Shoreditch now stands. But Stow assures us, that that street was so named before her time.

SHOREHAM, a town of the county of Sussex, in the rape of Bramber and hundred of Fishergate, fifty-six miles from London. It stands on the river Adar, about a mile from the sea, and has a bridge over that river. It has a custom-house, which presides over that at Brighton. The harbour is not deep, but useful as shelter, when the wind is high, for vessels unloading on the beach at Brighton, although there is scarcely any water when the tide is out. It is an ancient place, ill built, with few good houses. The church is old, and was originally monastic. It is a borough, which, on account of bribery in 1771, was extended, to comprehend all the forty shilling freeholders of the rape on which it stands, and still continues to elect two members to the House of Commons. There is some trade in building ships, and a considerable oyster fishery. A market, well supplied, is also held on Saturday. The population was, in 1801, 987; in 1811, 980; in 1821, 1282; and in 1831, 1734.

SHORT, James, an eminent optician, was born in Edinburgh, on the 22d of June in the year 1710. At ten years of age, having lost his father and mother, and being left in a state of indigence, he was received into Heriot's Hospital, where he soon displayed his mechanical genius, in constructing for himself little chests, book-cases, and other conveniences, with such tools as fell in his way. At the age of twelve he was removed from the Hospital to the High School, where he shewed a considerable taste for classical literature, and generally kept at the head of his forms. In the year 1726 he entered the university, where he passed through the usual course of education, and took his master's degree with great applause.

By his friends he was intended for the church; but after attending a course of theological lectures, his mind revolted from a profession which he thought little suited to his talents, and he devoted his whole time to mathematical and mechanical pursuits. He had been fortunate enough to have the celebrated Maclaurin for his preceptor, who having soon discovered the bent of his genius, and made a proper estimate of the extent of his capacity, encouraged him to prosecute those studies in which nature had qualified him to make the greatest figure. Under the eye of that eminent master, he began in 1732 to construct Gregorian telescopes; and, as the professor observed in a letter to Dr. Jurin, "by taking care of the figure of his specula, he was enabled to give them larger apertures, and to carry them to greater perfection than had ever been done before him."

In the year 1736 Mr. Short was called to London, at the desire of Queen Caroline, to give instructions in mathematics to the Duke of Cumberland; and immediately on his appointment to that honourable office, he was elected a fellow of the Royal Society, and patronized by the Earls of Morton and Macclesfield. In the year 1739 he accompanied the former of these noblemen to the Orkney Isles, where he was employed in adjusting the geography of that part of Scotland; and happy it was for him that he was so employed, as he might otherwise have been involved in a scuffle which took place between the retainers of Sir James Stewart of Barra and the attendants of the earl, in which some of the latter were dangerously wounded.

Mr. Short having returned to London, and finally established himself there in the line of his profession, was, in 1742, employed by Lord Thomas Spencer to make for him a reflector of twelve feet focus, for which he received six hundred guineas. He made several other telescopes of the same focal distance with greater improvements and higher magnifiers; and in 1752 finished one for the king of Spain, for which, with its whole apparatus, he received twelve hundred pounds. This was the noblest instrument of the kind that had then been constructed, and perhaps it has never yet been surpassed, except by the astonishing reflectors of Herschel.

Mr. Short used to visit the place of his nativity once every two or three years during his residence in London, and in 1766 he visited it for the last time. On the 15th of June 1768 he died, after a very short illness, at Newington Butts, near London, of a mortification in his bowels, and was buried on the 22d of the same month, having completed his fifty-eighth year.

Short-Hand Writing. (See Stenography.)

Short-Sightedness, a certain defect in vision, by which objects cannot be distinctly seen unless they are very near to the eye. (See Optics).

SHOT, a denomination given to all sorts of balls for fire-arms; those for cannon being of iron, and those for guns and pistols of lead.

Case Shot formerly consisted of all kinds of old iron, nails, musket-balls, and stones, which were used as above.

Shot of a Cable, on ship-board, is the splicing of two cables together, that a ship may ride safe in deep waters and in great roads; for a ship will ride easier by one shot of a cable, than by three short cables out ahead.

SHOUMSHU or Choumchoo, one of the Kurile islands, the nearest to Asia, thirty-six miles in length and twenty in breadth. It contains mines, which yield a small quantity of silver. There are large lakes abounding with fish, and the natives have an herb from which they extract brandy. There are only forty-four male inhabitants, who pay tribute to Russia. It is ten miles south from Kamtschatka.

SHOVEL, Sir Cloudesly, a distinguished British admiral, was born about the year 1650, of parents in the lower rank of life. He was first put apprentice to a shoemaker; but disliking this profession, he a few years afterwards abandoned it, and went to sea. He was at first a cabin-boy with Sir Christopher Mynns, but having applied to the study of navigation with indefatigable industry, his skill as a seaman soon raised him above that station.

The corsairs of Tripoli having committed great outrages on the English in the Mediterranean, Sir John Narborough was sent in 1764 to reduce them to reason. As he had received orders to try the effects of negotiation before he proceeded to hostilities, he sent Mr. Shovel, who was at that time a lieutenant in his fleet, to demand satisfaction. The dey treated him with a great deal of disrespect, and sent him back without an answer. Sir John dispatched him a second time, with orders to remark particularly the situation of things on shore. The behaviour of the dey was worse than ever, and upon Mr. Shovel's return, he informed Sir John that it would perhaps be possible, notwithstanding their fortifications, to burn all the ships in the harbour. The boats were accordingly manned, and the command of them given to Lieutenant Shovel, who seized the guard-ship, and burned four others, without losing a man. This action so terrified the Tripolins, that they sued for peace. Sir John Narborough gave so favourable an account of this exploit, that Mr. Shovel was soon afterwards made captain of the Sapphire, a fifth-rate ship.

In the battle of Bantry-Bay, after the Revolution, he commanded the Edgar, and, for his gallant behaviour in that action, was soon afterwards knighted by King William. Next year he was employed in transporting an army into Ireland; a service which he performed with so much diligence and dexterity, that the king raised him to the rank of rear-admiral of the blue, and delivered his commission with his own hands. Soon afterwards he was made rear-admiral of the red, and shared the glory of the victory at La Hogue. In 1694 he bombarded Dunkirk. In 1703 he commanded the grand fleet in the Mediterranean, and did every thing in his power to assist the Protestants who were in arms in the Cevennes.

Soon after the battle of Malaga, he was presented by Prince George to Queen Anne, who received him graciously, and next year employed him as commander-in-chief. In 1705 he commanded the fleet, together with the Earl of Peterborough and Monmouth, which was sent into the Mediterranean; and it was owing to him chiefly that Barcelona was taken. After an unsuccessful attempt upon Toulon, he sailed for Gibraltar, and from thence homewards with a part of the fleet. On the 22d of October, at night, his ship, with three others, was cast away on the rocks of Scilly; and all on board perished. His body was found on the island of Scilly, by some fishermen, who stripped it of a valuable ring, and afterwards buried it. Mr. Paxton, the purser of the Arundel, hearing of this, found out the fellows, and obliged them to discover where they had buried the body. He carried it on board his own ship to Portsmouth, whence it was conveyed to London, and interred with great solemnity in Westminster Abbey. A monument was afterwards erected to his memory by the direction of the queen. He married the widow of his patron, Sir John Narborough, by whom he left two daughters.

SHOUT, Clamour, in antiquity, was frequently used on ecclesiastical, civil, and military occasions, as a sign of approbation, and sometimes of indignation. Thus as Cicero, in an assembly of the people, was exposing the arrogance of Antony, who had had the impudence to cause himself to be inscribed the patron of the Romans, the people on hearing this raised a shout to show their indignation. In the ancient military discipline, shouts were used, first, upon occasion of the general's making a speech or harangue to the army from his tribunal. This they did in token of their approving what had been proposed. Secondly, they were used before an engagement, in order to encourage and spirit their own men, and fill the enemy with dread. This was a practice of great antiquity; but, besides, it wants not the authority of reason to support it; for as mankind are endowed with two senses, hearing and seeing, by which fear is raised in the mind, it may be proper to make use of the ear as well as the eye for that purpose. Shouts were also raised in the ancient theatre, when what was acted pleased the spectators. It was usual for those present at the burning of the dead to raise a great shout, and call the dead person by his name, before they set fire to the pile.

SHREWSBURY, a town in the liberty of the same name, and the capital of the county of Shropshire, 156 miles from London. It is situated on a peninsula formed by the river Severn, which nearly surrounds it, and over which are two stone bridges. It comprehends three parishes, with a church to each, which were formerly collegiate, namely, St. Alkmands, St. Marys, and St. Chads. The town was in ancient times well fortified, and had a strong castle towards the north, a part of which still remains, and the keep has been converted into a garden. There is a free grammar school, at present in high repute, for communicating classical instruction, which possesses some valuable exhibitions at Cambridge. It is well endowed, and has a good library and neat chapel connected with it. There is a county hall, a jail, two bridewells, and a house of industry. The streets are narrow, and some of them rather steep, and the greater part of the houses are of ancient construction and fashion. It is a borough, and the corporation has extensive judicial power within the liberty, though it is now commonly transferred to the assizes for the county, which are held here. Shrewsbury has some trade by the river Severn, and some by a canal, which connects it with Ellesmere, and other parts of the kingdom. The principal manufactory is that of flannels, many of which, indeed, are woven in Montgomeryshire, and brought to Shrewsbury to be finished, but many are made within the town, and of late years machinery has been extended for that purpose. There are likewise some linens, and some coarse woollen cloths made. The country around is highly fertile, and the two markets, on Wednesday and Saturday, are most abundantly supplied. The town returns two members to parliament, and gives the title of earl to the ancient family of Talbot. The population was, in 1801, 14,739; in 1811, 16,606; in 1821, 19,854; and in 1831, 21,227.

SHUGAWULPOOR, a large town of Hindustan, in the province of Malwah, situated on the north-east bank of the river Jummary. It consists of a fortified town or citadel, and extensive suburbs, in which are some good houses, and an extensive bazaar. It is a considerable market for shipped muslins, 65 miles E.N.E. from Oojain. Long. 76. 45. E. Lat. 23. 24. N.

SHUKASKU, a large village of Irak in Arabia, on the western bank of the Euphrates. It is a flourishing place, and carries on a brisk trade with Bussora, the Euphrates being navigable to this place by means of large boats. It is surrounded by rich pastures; on which are reared numerous horses.

SHUMSABAD, a small town of the Sikh territorial province of Lahore, situated on the east side of the Jhylum river, 100 miles N.W. by W. from Lahore. Long. 72. 15. E. Lat. 32. 16. N.

SHUNDRABANDY, a town of Southern India, in the district of Tinnevelly, 40 miles S.W. from Madura. Long. 77. 45. E. Lat. 3. 35. N.

SHUS, a large mass of ruins in the province of Khuzistan, in Persia, extending twelve miles from the Kerah to the Abzal. They occupy an immense extent of ground, and are supposed, by Major Rennel and Colonel Kinneir, to be the ancient capital of Susa.

SHUSTER, the principal district of the province of Khuzistan, in Persia, and composing a separate government. It constitutes the finest portion of Susiana, being watered by four noble rivers, and a multitude of smaller streams, by which means the land is fertilised, and rendered productive. But the bounties of nature are here blasted by the oppression and malignity of man, and the ignorant and rapacious rulers of Persia, causing devastation and ruin over all the territories subject to their sway. This wealthy province, accordingly, which was formerly rich in its productions of cotton, sugar, rice, and grain, is now a forsaken waste; from the Abzal to the Tigris, and the river which Colonel Kinneir considers the Gyndes, on the western side, and from the banks of the Karoon to those of the Shat-ul-Arab, all is dreary and desolate; and upon the east side of Shuster, a lonely wild, upwards of sixty miles in length, extends from that city to the entrance of the valley of Ram Hormuz. Even in the most flourishing parts of the country, namely, between Bundekeel and Dezphoul, the corn is reared by the officers of the government, and the richer citizens of Shuster and Dezphoul, the original cultivators of the soil being all ruined by the heavy contributions imposed upon them, and which had been exacted with such severity, as to drive them from their habitations. Ram Hormuz, which forms part of this district, is one of the most romantic valleys in Persia. It is ruled by five hostile chiefs, four of whom are brothers, and have each a castle, from which they make frequent sallies, and carry off the corn and cattle of their rivals.

Shuster, a city of Persia, the capital of the province of Khuzistan, and the residence of a Beglerbeg, is situated at the foot of the mountains of Bucktiari, on an eminence overlooking the rapid course of the Karoon, across which is a bridge of one arch, upwards of eighty feet in height; from the summit of which the Persians frequently throw themselves into the water without sustaining the slightest injury. The streets, as in most eastern towns, are narrow and dirty, though the houses are good, being principally built of stone; it is defended on the western side by the river, and on the other sides by the old stone wall, which is now fallen into decay. The ruins which still remain attest the former magnificence and extent of this city. Those most worthy of attention, are the castle, the dike, and a bridge. Part of the walls of the former, said to have been the abode of Valerian, are still standing on a small hill at the western extremity of the town. It is on two sides defended by a ditch, and on the other two by a branch of the Karoon. It has but one gateway, built in the Roman fashion, and formerly entered by a chain-bridge. Not far from the castle is the dike, built by Sapor, across the Karoon, twenty feet in breadth, and four hundred yards in length, with two small arches in the middle. It is built of culstone, bound together by clumps of iron; and having, from want of care, given way to the torrent, Prince Mahomed Ali Meerza, governor of Kermanshaw, has rebuilt it. Over the artificial canal, formed by the building of this dike, is a bridge built of hewn stone, consisting of thirty-two arches, twenty-eight of which are yet entire. This city is generallly believed to have been the ancient Susa, though Colonel Kinneir, and Major Rennel, both good authorities, rather assign the ruins of Shus as the site of this renowned capital. Long. 48. 59. E. Lat. 32. N.

SHROPSHIRE, or Salop, a county of England. (See Salop.)

SHROVE-Tuesday, is the Tuesday after Quinquagesima Sunday, or the day immediately preceding the first of Lent, being so called from the Saxon word to *shrive*, which signifies to confess. Hence Shrove-Tuesday signifies Confession-Tuesday, on which day all the people in every parish throughout England, during the Catholic times, were obliged to confess their sins, one by one, to their own parish priest, in their own parish-churches; and, that this might be done the more regularly, the great bell in every parish was rung at ten o'clock, or perhaps sooner, that it might be heard by all, and that they might attend, according to the custom then in use.

SHROUDS, a range of large ropes extending from the mast-heads to the right and left side of the ship, to support the masts, and enable them to carry sail.

The shrouds as well as the sails are denominated from the masts to which they belong. Thus there are the main, fore, and mizen shrouds; the main-top-mast, fore-top-mast, and mizen-top-mast shrouds; and the main-top-gallant, fore-top-gallant, and mizen-top-gallant shrouds. The number of shrouds by which a mast is sustained, as well as the size of the rope of which they are formed, is always in proportion to the size of the mast and the weight of the sail it is intended to carry.

Bowsprit shrouds are those which support the bowsprit. Bumpkin shrouds are those which support the bumpkins. Futtuck shrouds are shrouds which connect the efforts of the topmast shrouds to the lower shrouds. Bentick shrouds are additional shrouds to support the masts in heavy gales. Preventer shrouds are similar to bentick shrouds, and are used in bad weather to ease the lower rigging.

SHRUB, *frutex*, a little, low, dwarfish tree, or a woody vegetable, of a size less than a tree, and which, instead of one single stem, frequently puts forth from the same root several sets or stems.

SHUTTLE, in the manufactures, an instrument used by weavers, which guides the thread it contains, either of woollen, silk, flax, or other matter, so as to make it form the woofs of stuffs, cloths, linens, ribands, and other fabrics, by throwing the shuttle alternately from left to right, and from right to left, across between the threads of the warp, which are stretched out lengthwise on the loom.

In the middle of the shuttle is a kind of cavity, called the eye or chamber of the shuttle, in which is inclosed the spoul, which is a part of the thread destined for the woof; and this is wound on a little tube of paper, rush, or other matter.

SIAK, is a river and a large district of Sumatra. The district extends about 450 miles along the north-east coast. This district has a considerable trade, which is carried on by vessels from the coast of Coromandel, which supply cargoes of piece goods, and also raw silk, opium, and other articles, which they provide at Prince of Wales' island or Malacca, receiving in return gold, wax, sago, salted fish and fish roes, elephants' teeth, camphire, rattans, and other canes. Spars and masts, and large supplies of frame timber used to be imported by the Dutch East India Company for the use of Batavia. The maritime power of the kingdom of Siak has always been considerable.

The river Siak is one of the largest in the island, and discharges itself into the sea opposite Malacca in N. lat. 1. 40. From a survey ordered by the British government of Prince of Wales' island, it appears that from its mouth to the town of Siak, is sixty-five miles. The width of the river is in general from about a half to three quarters of a mile, and its depth from seven to fifteen fathoms; but on the bar at low water, there is only fifteen feet of depth, and there are several shoals near its mouth.

m.

SIAM, an extensive kingdom of India beyond the Ganges, situated principally between the 10th and 15th degrees of north latitude, in the heart of the great peninsula between India and China. It is bounded on the north by unknown tracts, that extend as far as Thibet and China; on the south it has the Gulf of Siam and the Malay peninsula; on the east it has ranges of mountains, by which it is separated from Cambodia and Cochin China; and on the west it is bounded by the Burmese dominions. The extent of this kingdom, like many others in the east, appears to have varied with the success of its arms. It formerly was estimated to extend in length three hundred and sixty miles, by three hundred in average breadth; but it has since been contracted by the encroachments of the Burmese within narrower limits. It may be considered as consisting of the extensive valley through which the great river Menan flows, on the banks of which all the principal towns are situated; and it possesses besides a great extent of sea-coast along the Gulf of Siam, which is but thinly inhabited, as the Siamese have an aversion to settle on the sea-coast, from their dread of the Malay pirates. The valley of the Menan is subject to be inundated during the rainy season by the periodical floods of that river, the artificial sites of the villages and the trees being the only objects that rise above the expanse of the waters. It is only this part of the country which is known to Europeans; and it is an extensive flat, consisting of alluvial land, with many extensive morasses, from which the exhalations under a tropical sun are noxious to Europeans, causing fluxes, dysenteries, and acute fevers. In those tracts which are beyond the reach of the inundations, the country is parched and dried up.

Soi nd pro cts.

The country is described by those who composed the British embassy which accompanied Mr. Crawfurd to Siam in 1822, as rich and fertile in a high degree, and possessing extensive commercial resources. This is almost entirely owing to the peculiar fertility of the soil, very little of the merit being due to native industry, except in the formation of canals. It is to the overflowing of the river Menan and its numerous tributaries, that this fertility is owing. The country yields the most abundant crops of rice and of other plants, which require a redundant supply of moisture. Wheat is also reared on the higher grounds, but not in any great quantity, so that it requires to be imported for the use of the Europeans who reside here. All the richer productions of the tropical climates would also thrive in the same place; but there is little industry amongst the people, who are depressed by the tyranny of their rulers, and have no encouragement to cultivate the country. There is no country in the world where all sorts of fruits, the most luscious and exquisite, arrive at greater perfection. The pine-apple, the tamarind, and the banana, abound in Siam. Of the mangoes, there are not less than thirty species, all excellent; and so is also the coffee plant. The sugar cane grows to perfection, though only for home consumption; for the rude natives do not possess the art of refining it. The areka and the betel-nut are produced; the latter is exported in considerable quantities by the Portuguese in their ships, and also in Chinese junks. Pepper, on the other hand, is not reared to nearly the same extent as in Java. The cocoa nut is a great resource to the indolent Siamese. It is applied to numerous uses; its milk seasons many of the dishes, and the oil affords an excellent seasoning; it is also used for torches, and as a kind of pitch, which, when clarified, is well adapted for painting. Here are, besides, many medicinal plants and gums, and also oil of jessamine, benzoin, lack, crystal, emery, antimony, oil, wax, lack varnish, wild cinnamon, cassia buds, and iron wood, the last of which is much used by the natives as anchors for their vessels. Cotton grows abundantly, and is as fine as silk; "but," says a European visitor to this country, "these wretches do not know how to value it beyond stuffing beds and pillows."

Siam Animals.

Siam abounds in all the wild animals known in the tropical countries, which find ample cover in the deep forests of the interior. The elephant ranges in the outskirts of the kingdom, amongst the mountains and jungles which form its eastern and its western boundary. The hunting of this animal is a royal monopoly; a great number are taken every year, the finest of which are selected for the studs of the king and nobles, and the rest are exported to other parts of India. The white elephant is found in some parts; it is a very rare animal, and is so prized, that it has occasioned wars between sovereign states. The rhinoceros also frequents the forests, whose skin is much sought after as an object of trade. He is a dangerous animal when enraged, and is not easily overcome, as his skin is so hard that it can hardly be penetrated by a musket ball. But one of the most numerous and most dangerous animals found in the woods is the tiger, which grows to a large size, and is remarkably fierce in the interior regions of Siam. The monkey race are in vast variety, and spread over the cultivated fields, which they speedily lay waste. There are numerous other wild animals, namely, lizards of various kinds, cameleons, tortoises, hedgehogs, and a species of porcupine, which yields valuable bezoar.

The domestic animals are horses, cows, buffaloes, sheep, goats, and elephants. There is abundance of common poultry; and besides, peacocks, pigeons, partridges, snipes, parrots, and other birds. The horses are very inferior, the best being imported from Batavia; and the same may be said of all domestic animals except the hog, the flesh of which is superior to the same animal in Europe. Insects and vermin abound here as in other parts of India; and the sea and rivers yield abundance of excellent fish, on which a great proportion of the lower classes subsist. There are besides lobsters and turtle of a good quality, and the manjo fish, which is so much esteemed in Calcutta.

Minerals.

The mineral riches of Siam are but little known. It is inferred that gold must exist in the mountains, as it is collected in small quantities in the streams, by which it is washed down. Iron, tin, lead, and copper, are likewise procured, but in small quantities. The copper is of a good quality. Iron is imported in considerable quantities from Europe, no diligence being employed to procure it in the country. The mountains in the interior yield diamonds equal to those in Hindustan, also sapphires, rubies, and agates.

Trade.

The Siamese, from the fertility of their soil, and the facilities of internal traffic afforded by the numerous streams and canals which everywhere intersect the country, are less dependent than most other nations on foreign trade. They are supplied chiefly by the Chinese, who, from their similarity of character and other causes, are the only people permitted to trade freely here. The Chinese commerce with Siam is said to be very extensive, and to employ no less than from 30,000 to 40,000 tons of shipping annually in the port of Bankok alone. It is to the supple character of the Chinese, the long connexion that has subsisted between the two countries, and the number of that nation resident in Siam, that this great trade is to be ascribed. The articles which chiefly attract the Chinese traders, are sugar, sapan wood, of which 18,000 tons are exported annually, pepper, cardamoms, sharks fins, birds' nests, beche de mer, hides, about 200,000 of which are exported annually; bones of the elephant, the rhinoceros, the tiger, the deer, and the buffalo; indigo, cotton, wines, and a variety of smaller articles. The Chinese traders, in their junks, arrive every year in February, March, and April, from Hainan, Canton, Soukah, Amoy, Ningpo, and other places. They take away, besides the above articles, a considerable quantity of culmin. There are annually about eighty vessels, mostly freighted by Chinese settlers at Bankok, or Siamese nobles, some of whom engage in traffic. Rice and salt of the very best quality are exported to all the European settlements to the eastward.

Among the articles produced in smaller quantities, but which are still valuable for Indian or European cargoes, are agil-wood, a perfumed or scented wood, benjamin, ivory, and stick lac. Iron, formed into cooking utensils, forms an extensive article of export from Siam. There are four American ships come annually for cargoes of sugar, for which they pay in dollars.

Siam carries on a considerable trade with the British settlement of Singapore. This trade is chiefly managed by the Chinese, either natives from China, or their descendants settled in Siam, the Siamese being an indolent race, devoid of the spirit of industry or of enterprise. The vessels and cargoes belong invariably to the Chinese. The principal articles which they import, are British piece goods, or goods of Indian manufacture, such as Bengal muslins, chintz, gurrahs, and sannahs; gold dust, bees' wax, gambier, rattans, tea, sago, sea-weed, cowries, and coarse paper, likewise constitute articles of import. In addition to those articles, cotton twist is much in demand. Amongst the imports into Siam, opium is one of the most important, about two hundred and fifty chests of this article being annually consumed. It is brought chiefly in junks, from Penang and Singapore; and though a contraband article, for a length of time met with a safe and speedy sale, the very persons appointed to enforce the prohibition being the principal dealers. But since the laws have been so rigidly enforced against the importation of opium into Canton, and the whole stock seized by the Chinese authorities, the dealers of it being besides threatened with death, and the British resident, Elliot, seized and imprisoned, the same severities have been enforced against the trade in Siam. The laws are equally strict against the importation of the drug, a severe fine being the penalty, which, if the offender cannot pay, as is commonly the case, his goods are confiscated; and if the sum raised be still insufficient, he is condemned, with his whole family, to perpetual slavery. In June 1839 several unfortunate Chinese sailors were accordingly seized with opium on board, from Singapore, and were cast into prison, where they were treated with great severity.

No impediment is offered to the admission of European ships into the Siamese ports; nor are the imposts heavy. The port charges for a ship of three hundred and fifty tons do not amount to more than 1200 dollars, and the duties on imports are generally eight per cent., though many articles are free. Sugar pays 3s. 2d. per cwt. The real impediments to commerce, consist in the privileges of the king, who is, properly speaking, the only merchant in the kingdom, as he claims the right of pre-emption in the market, from which he derives a large profit. His agents are hard to deal with. They regard foreign trade merely as a source of dishonest profit; and European vessels are only admitted to give an opportunity for extortion. It was to procure the abolition of those oppressive monopolies that Mr. Crawfurd's embassy was sent to Siam in 1822. But he failed entirely to attain this object.

The Menan, by which ships enter, discharges itself into the Gulf of Siam; but it has a bar at its mouth, to cross which, the aid of a pilot is required. The southerly monsoons is the best season for ships to visit Siam, and the northerly for returning to Hindustan, through the straits of Malacca. Bankok, situated on the river near the bay, is the chief place of trade. It is capable of making little defence against a European force; it is indeed, in a military point of view, quite defenceless; nor is there any fortification at the mouth of the river, or all the way up to the capital. A fleet of prows constitutes the whole naval defence of the kingdom of Siam, the bar of the river affording a defence against vessels of war.

Government.

The sovereign of this country exercises, as in other eastern kingdoms, absolute sway. He has no hereditary nobility of any kind, nor any popular assembly to controul his supreme will. The whole male population are liable to military conscription. Their names are enrolled in a register, and they are bound to perform military service for six months in the year; they receive no pay, carry their own provisions, and are only provided with arms and accoutrements. The country is divided into districts, and a chief is placed over each, under whose colours they march to battle. They have made no progress in the science of war, and possess neither discipline nor courage. Like the Burmese, they trust to fortifications of stockades of trees, and posts encircled by a ditch. But the real defence of the country consists in the natural obstacles of jungles, morasses, and the branches of rivers by which it is everywhere intersected. They march without order, nor do they take any precautions against a surprise. They seldom stand more than one discharge, which is sure to frighten one or other of the parties engaged, when they quit the field in disorder. Their chief dependance is on their elephants, which, when they are frightened or wounded, become equally formidable to friends and foes. There is nothing like a standing army. A body of guards, composed chiefly of foreigners, who are attached to the person of the sovereign, is the only force which is not disbanded. They are chiefly Tartars, with a corps of Mohars, who frequently display a desperate courage, however, said to be owing to the stimulus of opium. A small part of the taxes is levied in money, the greater part of the revenue being received in kind.

The rules followed in the administration of justice, are rude and barbarous. The tribunals are composed of three members; but the president alone decides. By the laws of Siam, children are clothed for the first time, at the age of four or five; and they are never afterwards uncovered for chastisement. Parents may sell their children. But they never resort to this proceeding except from absolute want. It is not true, as has been reported, that they sell their daughters, if offended with them, for courtezans. The duties between a pupil and his teacher are reckoned next in importance to those of parent and child. Their system of education resembles that of the Burmese. Priests are not allowed to become teachers of the female sex. The principal object of their education is to enable them to superintend their husbands' affairs. Marriage is considered merely as a civil contract, and the priests are not called upon to assist in it. Polygamy is admitted, but is only practised by the higher classes; and even they consider the first wife only as mistress of the house, whilst all the rest are little better than slaves. In general, the lot of the females is severe in this country, the heaviest part of the labour falling upon them; nor are they allowed to eat with their husbands, nor even to sail in the same boat; they attend no public amusements, but spend their time almost entirely at home. In every intricate case, the ordeal is resorted to as the easiest solution of all difficulties. The accused is required, as a satisfactory purgation of his innocence, to walk over red hot iron, or burning coals. Another ordeal is by water, when the person who remains longest beneath is declared innocent. Pills that cause vomiting are also employed; and he on whom they first take effect is adjudged guilty. But in some cases, the accused are subjected to the perilous test of being thrown to tigers, which in their fury, will, it is supposed, make the proper distinction between the innocent and the guilty. The punishments, as in all barbarous countries, are shocking by their severity. Sacrilege is punished by fixing the head of the offender to the hearth, where it is consumed by a slow fire. A stake is thrust through the body of assassins, in such a manner as to cause exquisite pain. Noblemen are sometimes subjected to degrading punishments, being condemned to cut grass for the elephants; some are subjected to the pillory; others are allowed to languish in prisons in the most miserable state, or they are seen wandering about the city, chained seven and seven together, begging their bread from door to door. They are confined at night within a circle formed with stakes, and are obliged by turns, and at short intervals, to call out their names.

R ion.

The religion of Siam is the same system which has diffused itself so extensively over the east and north of Asia, which is variously designated in different countries, as the doctrine of Boodh or Buddha, or of Gaudama, and in Tartary of Shamanism. The language of their sacred books, like the Sanscrit and the Zend in Persia, differs entirely from that in ordinary life, and is called Bali, apparently the same Indian language which is called Pali by the Burmans. The creed is singularly severe; but the common people escape from its austerities, as they believe that a rigid adherence to its maxims is only prescribed to the priests, to whose mortifications they trust as an atonement for their errors. They have an order of monks professing celibacy, and residing in convents. They harangue the people from morning to night, who not only express their feelings in murmurs of applause, but load the preacher with costly gifts. Their temples are distinguished above all those in Asia, by their magnificence, and by the gigantic statues which they contain. The principal pagoda in the city is of a long and narrow form, covered externally with tin, whilst the interior is one complete blaze of gold, and contains an idol, forty-five feet in height, which reaches to the roof, and is said to be composed entirely of that precious metal.

Sci e, lite ure, &c.

The Siamese have made scarcely any advances either in science or literature. Their progress in mathematics is not great, their attention being confined chiefly to arithmetic, on account of its utility in commerce. They know little of astronomy beyond some of its humblest practical applications. They first learned from Cassini to find out the place of the sun and moon by calculation. But they have not turned their knowledge to any account in navigation, their junks making use merely of the compass, and creeping where they can along the coasts for safety. Time is measured by vessels having a small hole perforated and placed in a tub of water, the construction of clocks being beyond their mechanical powers. Their system of medicine is equally imperfect, consisting chiefly in certain receipts, the virtues of which they say have been ascertained by experience. They are entire strangers to anatomy, having a religious scruple against opening dead bodies. They are fond, like many other barbarous nations, of music and poetry, and their bards are chiefly exercised in songs and in impromptu recitations. Their festivals and pleasure excursions upon the water are always enlivened with music. Their taste, however, appears to be equally rude in this as in all other arts or sciences. Instrumental music is chiefly valued on account of its loudness; the organ is preferred on this account to any other European instrument; and next to it hautboys, drums, trumpets, and fifes. Their theatrical amusements are, as might be expected, extremely rude, consisting of extravagant fables or gross caricatures, often levelled against the reigning monarch, or against persons in power, who choose to wink at these liberties, being the only vehicle of public opinion. Dancing and wrestling are amongst their most favourite amusements; and their puppet shows, the theatrical exhibitions in which they chiefly delight, are got up with great parade and expense by the king and the nobles for the amusement of the people.

Mor ha- racter

The moral character and habits of the Siamese are rated extremely low by those travellers who have visited the country. From the highest to the lowest, they are, according to their account, mean, cowardly, and mercenary. Like most of the Eastern nations, they have no regard to truth. These bad qualities are perceived in every action of their lives; and their rapacity in their intercourse with strangers is well known. To increase their wealth and promote their own interest, form the lasting object of all classes, which is pursued by every indirect and fraudulent practice. Timidity is a remarkable characteristic of the nation, insomuch that two Europeans would put to flight fifty of them; and the doctrine that cruelty and cowardice go together, is exemplified in their treatment of those who are made prisoners in their wars with the Burmese, or are kidnapped on the frontier; they are employed in public works of the most servile nature, with chains about their necks, legs, and feet, and are condemned to this degradation for life. Amongst their other evil propensities they carry on gambling to a great excess; and some have attributed the low state to which trade has occasionally fallen, to a species of lottery, in which all classes engage, and which is countenanced by the king. To such a length is the rage for these gambling speculations carried, that it is the cause of serious disorders. The victims of this vice, impoverished, and reduced to nakedness, betake themselves to open and lawless violence for subsistence. They follow robbing as a trade, and herd together in bands, so that it is not safe to venture out in decent attire, as they plunder openly, and commit daily murders.

Population

Europeans have no very accurate knowledge of the statistics of Siam, and the estimate of the population by different travellers is rather conjectural. According to such imperfect statements as have been received, the entire population of the country was stated at four millions. The inhabitants resemble the Chinese and Mongols in their features; they have a broad face, and very prominent cheek bones, whilst the remainder of their cheek has rather a hollow appearance. The eyes are small, with a deep yellow tinge in the white part; the mouth large, and the lips thick and full. Both males and females take as much pains to blacken their teeth, as the Europeans do to preserve them white. The men eradicate their beards, but allow their nails to lengthen like the Chinese. They are extremely gross feeders, eating rats, buzzards, grasshoppers, and other insects. They are, as has been already stated, indolent, and have made no progress in mechanical arts, nor in agriculture. It is chiefly by the Chinese that the country is cultivated, and that sugar and other productions are raised. They, along with the Portuguese settled here, manage the commerce that is carried on. They are strangers to the making of silk and woollen cloths; and even the fabrics of cotton are not nearly on the same scale as in Hindustan. Their artists in gold are however remarkably expert, and their fillagree work is extremely beautiful. They also excel in beating out gold leaf, which is greatly employed in adorning their temples and idols.

History.

The Siamese annals affect to detail with much minuteness the events that have occurred in Siam and the adjacent states and countries for the last fourteen hundred years; but these, like most Eastern histories, consist of fables or gross exaggerations. The kingdom of Siam was unknown in Europe until the discovery of the route to India by the Cape of Good Hope. The first traces of their history were received through the Portuguese, who frequently acted as auxiliaries to the contending factions. In 1684 ambassadors were sent from Siam to Louis XIV., and in consequence M. Cerberet and La Loubère were dispatched as ambassadors to Siam, where they arrived in 1687, and immediately attempted to make a proselyte of the king to the Catholic faith. The monarch declined the religion so freely proffered to him by the French, but entered into a strict alliance with them, and allowed them two garrisons, Bankok and Mergui. In 1688, the king was, however, by a sudden revolution, dethroned and murdered, which was followed by the expulsion of the French. From this period Siam was the scene of much internal discord, and of many sanguinary massacres; and in 1754 was involved in a serious war with the Burmese, who having conquered Pegu, and enlarged their territories, came in contact with the dominions of Siam. A long war ensued, which terminated altogether to the disadvantage of the Siamese, who were repeatedly defeated with great slaughter; their capital was sacked by the Burmese in 1766, who besides took all their maritime possessions on the bay of Bengal and along the west coast of the Malay peninsula, including the important places of Tavoy, Mergui, and Tenasserim. Though greatly reduced by this unsuccessful war, and frequently brought to the brink of ruin, Siam still exists as an independent kingdom, to which it is indebted partly to the dissensions of the Burmese, and partly to the actual strength of the country.

An embassy was sent to Siam by the British government in 1822, which was placed under the charge of Mr. Crawfurd, who had an audience of the king of Siam, by whom he was received so favourably, that he had every reason to expect a favourable termination to his mission. But these hopes were frustrated by the jealous and unaccommodating policy of the government. They made propositions one day which were revoked the next; and displayed their faithless character so clearly, that all negotiations were finally broken off; and the embassy were finally interdicted from going about the town or on the river, and were not allowed to trade. An American embassy was more agreeably received by this jealous government in 1833, and it is said succeeded in concluding a commercial treaty with the government. *Asiatic Journal*, new series. Hamilton's *Gazetteer*.

SIBERIA, a vast tract of territory comprehending the northern regions of Asia, which has been partly described under Russia; so that it will only be necessary in this place to supply some particulars which have not been so fully detailed in the former article. Siberia may be considered as a gradually descending plain from the Altai mountains to the Frozen Ocean, which is indeed indicated by the course of all the great rivers, the Obi, the Jenesei, and the Lena, which flow from these mountains in a northerly course until they terminate in that sea. Although under the dominion of Russia, and of regular government, improvements have been gradually diffused amongst its rude tribes; and although cities, some of them populous and thriving, have risen up, yet it is on the whole a barren and unproductive country, the predominance of cold throughout the greater part of it chilling the progress of vegetation, and preventing either fruits or grain from arriving at maturity. Nor, though it is by no means destitute of rivers, is the direction which they take calculated to favour the course of commerce, or to give facilities for the transmission of its productions from one part of the country to another. Flowing, as already stated, from south to north, they run out of the regions of civilization and commerce into those of perpetual winter; they lead into inhospitable deserts, to which there is no resort either of goods or of men; and therefore they are, and will ever remain, useless for the purposes of trade, and of little use to the country through which they flow. Nor is there by sea any easy access to this cold and inhospitable tract. The Frozen Ocean on the north presents an insuperable barrier to navigation; and the eastern shore, washed by the Pacific Ocean, is so far removed from the great seats of wealth and commerce in Europe, that no great intercourse can ever take place. Siberia has no surplus produce that can tempt a European vessel to perform the circuit of half the globe in order to obtain it.

History.

This region was unknown in the ancient world. The knowledge of the Greeks and Romans did not extend beyond Scythia, or independent Tartary; they were altogether ignorant of the vast regions which lay farther to the east and north, from which issued those vast hordes of barbarians who overthrew the Roman empire. During the devastations and wars which succeeded, and by which the great empires of Asia were shaken and thrown down, a greater knowledge was obtained of these northern regions, especially by the Mahommedan conquerors; but it does not appear that they ever penetrated into these districts, or that they were ever thoroughly explored until the progress of Russian conquest brought them under the sway of this rising power, which did not take place till the middle of the sixteenth century. In the reign of John Basilowitz I., indeed, an incursion had been made into Siberia, and some Tartar tribes subdued; but these conquests were not permanent, and we hear of no further communication between Russia and Siberia till the time of John Basilowitz II. It was opened again at that time by means of Anika Strogonoff, a Russian merchant, who had established some salt-works at a town in the government of Archangel. This man carried on a trade with the Samoiedes who inhabited the banks of the Obi and the Petchora, and who are accustomed to come along the river Vitenegda to its confluence with the Dwina, where they exchanged their furs with the Russians. He acquired in this manner a considerable fortune in a short time; and he determined on exploring the districts whence these valuable commodities were derived. He sent thither a party of his dependents, who, in exchange for Dutch toys and other trifles, obtained the most valuable furs. He judged it prudent, after he had carried on the trade for some time, to communicate the whole affair to the brother of the reigning emperor, Theodore Iwanovitch, and ultimately his successor. The Czar perceiving the advantage that might be derived by his subjects from a regular intercourse with Siberia, despatched a body of troops into that country, chiefly needy adventurers, who crossed the mountains that form the north-eastern boundary of Europe, though they never seem to have passed the Irtysch, or have penetrated beyond the western branch of the Obi. The people they met with were rude and barbarous; they were small in stature, destitute of towns and villages, ignorant of bread, and subsisting entirely by fishing and the chase. They were struck with the novelty of what they saw, and with a variety of unknown animals; with men riding on elks, or dervises mounted on sledges drawn by rein-deer or dogs. The natives received with high gratification the presents that were brought to them, and they eagerly in return desired to visit the Russian capital, of which their visitors had given them a splendid description. They were dazzled with the magnificence of Moscow and the emperor. Some Tartar tribes were laid under contribution, and a chief named Yediger consented to pay an annual tribute of a thousand sables. But this produced no lasting advantage to Russia; for, soon afterwards, Yediger was defeated and taken prisoner by Kutchum Khan, a descendant of the great Genghiz Khan; and thus the allegiance of this country to Russia was dissolved.

For some time we hear of no further attempts made by the Russians on Siberia; but in 1577 the foundation of a permanent conquest was laid by Yermac Temofeeff, a Cossack of the Don. This man was at first the head of a banditti who infested the Russians in the province of Casan; but being defeated by the troops of the Czar, he retired with six thousand of his followers into the interior parts of that province. Continuing his course still eastward, he came to Orel, the most easterly of all the Russian settlements; and here he took up his winter quarters. But his restless genius did not suffer him to continue for any length of time in a state of inactivity; and from the intelligence he procured concerning the situation of the neighbouring Tartars of Siberia, he turned his arms towards that quarter.

Siberia was at that time partly divided amongst a number of separate princes, and partly inhabited by the various tribes of independent Tartars. Of the former Kutchum Khan was the most powerful sovereign. His dominions consisted of that tract of country which now forms the south-western part of the province of Tobolsk, and stretched from the banks of the Irtysch and Obi to those of the Tobal and Tura. His principal residence was at Sibir, a small fortress upon the river Irtysch, not far from the present town of Tobolsk, and of which some ruins are still to be seen. After a course of unremitting fatigue, and a series of victories which almost exceed belief, but of which we have not room to give the detail, our intrepid adventurer dispossessed this prince of his dominions, and seated himself on the throne of Sibir. The number of his followers, however, being greatly reduced, and perceiving he could not depend on the affection of his new subjects, he had recourse to the Czar of Muscovy, and made a tender of his acquisitions to that monarch, upon condition of receiving immediate and effectual support. This proposal was received with the greatest satisfaction by the Czar, who granted him a pardon for all former offences, and sent him the required succours. Yermac, however, being soon after drowned in an unsuccessful excursion, the Russians began to lose their footing in the country. But fresh reinforcements being sent, they not only recovered their ground, but pushed their conquests far and wide; and wherever they appeared, the Tartars were either reduced or exterminated. New towns were built, and colonies were planted on all sides. Before a century had elapsed, all that vast tract of country now called Siberia, which stretches from the confines of Europe to the Eastern ocean, and from the Frozen sea to the present frontiers of China, was annexed to the Russian dominions.

Cli te.

The air of Siberia is extremely piercing; and it is remarked that in advancing eastward it becomes more intense. M. Gmelin, who was sent to explore this country in 1733, gives some remarkable examples of the extreme cold which prevails. He mentions, that at the foot of Kiringa, on the 10th of February 1738, the mercury, at eight in the morning, stood at 254 in the thermometer which he had along with him, and which answers to 72° in Fahrenheit below 0. In December, at the same place, it answered to 90° in Fahrenheit below zero, about three in the afternoon; and afterwards in the course of the same month, to 99, 107, and 113 below 0, the greatest cold answering to 120° in Fahrenheit below 0. At this time sparrows and magpies were seen to fall to the ground struck dead with the intense cold, but revived if they were speedily brought into a warm room. The air at this time is represented as if it were changed to ice, a thick fog, not dissipated by any exhalations as in spring and autumn; and the writer states that he could scarcely stand three minutes in the porch of his house for cold. At Yakutsk, on the Lena, in November, Captain Cochrane[1] mentions that Reaumur's thermometer stood at 32° and 35°, which answers to 40° and 46° in Fahrenheit below zero; in his journey to Irkutsk it stood at 30° of Fahrenheit, and 35° below zero; and on the 13th of January the rapid waters of Angora were bound up by the frost, and it became passable on the ice. The Siberian rivers are however frozen earlier, and it is late in the spring before they are thawed. The northern and eastern districts of Siberia are rendered unfit for agriculture by the excessive cold. The whole tract beyond the 60th degree of N. lat. is a barren waste, yielding neither corn nor fruits. Pallas mentions, that to the north of Demiansk, a village in the government of Demiansk in about $59\frac{1}{2}$° N. lat., hardly any thing is reared but barley and oats, at most but a little grain. Hemp and flax are sown, but in three years they have scarcely one tolerable crop. The cabbage that is sown produces no head, but spreads itself in loose green leaves. The repeated attempts that have been made about Okhotsk, between 59° and 60° N. lat., and 160° E. long., or at Udskog-Ostrog, 50° 20′ lat., 150° 40′ long, to cultivate corn, have been entirely unsuccessful, the long winter, and the night frosts in autumn preventing either fruits or grain from coming to perfection; and in Kamtschatka, where the southernmost course terminates in 51° N. lat., similar trials have been made without success. A great part of the Siberian territory that is situated in a more temperate climate, being composed of marshy and saline steppes, is extremely barren. But there are other tracts that are equally productive, that not only abound in extensive pastures, but produce abundance of grain, not of wheat, but of barley, rye, and other inferior descriptions; whilst farther south there are districts of remarkable fertility. Amongst the Ural and other ranges of mountains, rich and verdant vales and glens are to be met with, which afford pastures for numerous herds of cattle; a remarkably wealthy district extends along the heart of the Tobol, Iset, and the Issim, and is so abundant in grain, that it supplies the government of Tobolsk, as well as the provinces of Perm and Orenburg. Also in the territory of Krasnoyansk, a circle town of the government of Kolhyvan, between 55° and 56° of N. lat., such is the fertility of the soil, notwithstanding the severe and continued winter, that no instance was known of a general failure.[2] This fertile tract commences at Krasnoyansk, and extends to Baikal and the surrounding countries. The quality of the soil is here so rich, being of a black and light mould, that it rejects the use of manure. Most of the fields, if they are left fallow for one year, continue to bear ten or fifteen years more. In consequence of this fertility, provisions are abundant and cheap. Not only are oats, barley, and rye cultivated, but also wheat, though it is not so abundant. These countries, which, if they were industriously cultivated, might give subsistence to populous nations, are chiefly covered with pastures. Beyond the lake Baikal, especially towards the east, as far as the river Argun, they are remarkably fruitful and pleasant; but such is the indolence of the inhabitants, that several fine tracts of land, which would make ample returns to the peasant for cultivating them, lie neglected. The pastures are excellent, and abound in fine horned cattle, horses, goats, and other beasts, on which the Tartars chiefly depend for subsistence. However, there are several steppes or barren wastes, and unimproved tracts in these parts; and not a single fruit tree is to be seen. There is great variety of vegetables, and in several places, particularly near Krasnoia Sloboda, the ground is in a manner overrun with asparagus of an extraordinary height and delicious flavour. The bulbs of the Turkish and other sorts of lilies, are much used by the Tartars instead of bread. This want of fruit and corn is richly compensated by the great quantities of wild and tame beasts and fowls, and the infinite variety of fine fish which the country affords.

In that part of Siberia which lies near the icy sea, as well as in several other places, there are woods of pine, larch, and other trees; besides which, a considerable quantity of wood is thrown ashore by the waves of the icy sea, but whence it comes, is not yet ascertained. On the Ural mountains also, are found pines, birch, fir, cedar, larch, aspin, alder; and on the opposite side a few oaks, elms, lindens, and other trees.

The extreme rigour of the climate, which stunts the vegetation of Siberia, has no effect on the animal creation, which abounds in the most frozen and desolate tracts. Nature, in protecting from the rigour of the cold those animals with a thick fur, which in its rich gloss and softness no art can rival, has rendered them valuable, and they are accordingly hunted for their skin, which forms an important article of commerce. Of all these furs, the most valuable is the sable, which is found on a species of weazel. This animal is met with in Asiatic Russia, from the Aleutian islands, and from Kamtschatka to the districts of the Petschora and the Kama. The finest sables are those which come from Yakutsk and Wertschink; and amongst these are found the rare and precious yellow, and still more rarely, the white sable. In Kamtschatka, these precious furs are to be found in the greatest abundance, but not of so fine a quality; the skin being thick, and the hair long, but not very black. When this country was first invaded by Europeans, these animals were in such abundance, that for iron wire to the amount of ten rubles, sables might have been obtained to the amount of five or six hundred. But the animal has been so diligently hunted, that it has become scarce, so that one skin may be exchanged on the spot for ten pounds. The great art is, to catch the animal without injuring the skin, for which purpose various contrivances are resorted to. The hunter, following the track of the animal, discovers his covert, which is usually a burrow in the earth; the animal, to escape him, ascends a hollow tree, which the hunter immediately surrounds with a net; and kindling a fire under it, forces the little creature to descend, when it falls into the net and is caught. Various other animals are hunted for their skins, which form a considerable article of commerce. Wild-fowl abound every where in Siberia, namely, wild ducks and geese, swans, woodcocks, snipes, bustards, snow-birds, pheasants, partridges, &c.; these are so plentiful, that even in the governments which are the poorest in wild animals, they form an ordinary and not very costly dish. The eider fowl, which supplies the fine and soft down that is so much esteemed in all countries, harbours about the coasts of the White Sea and the Northern Ocean. In Siberia are found the prodigious remains of animals, none of which are now found to exist; the bones and entire carcase of the mammoth, that extraordinary animal, which surpasses in bulk every known species, is found preserved in the ice on the shores of rivers in the north, and on the coasts of the Frozen Ocean. The bones of the elephant and rhinoceros occur also in vast quantities. The seas that wash the coasts of Siberia, and the rivers, teem with a great variety of marine animals and with fish. The Frozen Ocean and the Eastern Seas abound in whales, seals, otters, also the narhwal, the pott-fish, from whose brain spermaceti is prepared, the sea dog, the dolphin, the sea lion, the sea cow, the sea bear, and various other species, which are sought after for their skin or their blubber. The Obi abounds beyond all the others in vast quantities of migrating fish which pass from the sea; not only those which are found in other rivers, but a variety of fish which are caught no where else, namely, sturgeons, starlet, white salmon, pikes, murœna, or white salmon of Pallas, quobbe, and a multitude of other fish, of which the Russian names would convey no information to the reader. The migrating fish proceed up the rivers in June, and the fishing in the Obi is carried on by the Ostiacks and Samoiedes. The Irtysch, the Jenisei, and the Lena, as well as their numerous tributaries, contain abundance of excellent fish, mostly resembling those already named. The fishing on the coasts and islands of the Eastern ocean is remarkable for the variety and quality of its objects; and as agriculture is here impracticable from the soil and the climate, the inhabitants depend for their subsistence on the fishing, and the chase. All the large cetacea of the Arctic seas are here pursued with avidity, and the oil which they afford forms an article of commerce. Of all the lesser animals which are objects of the chase on the Eastern ocean, the sea otter is the most important. Its beautiful fur is everywhere highly esteemed, and sells in China for a very high price. The rivers in Kamtschatka abound more especially with fish, which supply the inhabitants with subsistence, which no labour could extract from the barren soil. These fish, which are mostly of the salmon kind, proceed up the rivers in such vast multitudes, that the shores are often found covered with the dead.

[2] Tooke's View of the Russian Empire, vol. iii. p. 238.

Mountains

The surface of Siberia is diversified by alternate ranges of mountains and by widely extended plains. The Ural mountains, so called from the Tartar word signifying a belt or girdle, which form the natural boundary between Asia and Europe, extend almost in a direct line above 1500 English miles. The mountains between the Caspian and the Aral may be considered as the commencement of the Ural mountains; which, after being divided by the straits of Weygat, terminate in the mountain chain of Nova Zembla, several subordinate ridges branching off in a western, as well as in an eastern direction, from the same chain. These mountains are rich in minerals, and they are in many parts also clothed with tall firs, larches, birch, and other woods. They are well watered by rivers, and at different degrees of elevation are found beautiful pellucid lakes, ponds, and numerous streams, all teeming with fish. The breadth of the Ural mountains at Sollkamskoi and Verchoturia, the high road out of European Russia, is about forty miles, and their height from four to five thousand feet. At their northern extremity, along the lower Obi, their elevation is not so great. The Ural mountains, at their northern extremity, lock in by several ridges with the great Altaic chain, which traverses northern Asia from west to east through its whole extent, and fix the respective limits of the Chinese empire from the Irtysch to the Amour. The great Altai stretches northward beyond Siberia, into the regions of Tartary; and proceeding with various windings toward the N.N.E., throws out considerable masses, between which the head waters of the Jenesei, the Obi, and the Irtysch, take their rise; and the lesser Altai separates the Chinese territories from the Russian government of Kolivane, through which the streams mentioned above pursue their course. Near its summit a Chinese patrol was found guarding the limits of the empire by the traveller Shcangin. The highest mountains consist of granite, and are covered with perpetual snow. The lower mountains consist of porphyry, jasper, and serpentine, and exhibit many beautiful varieties of these rocks. The highest summit of these mountains, in the government of Kolivane, does not rise more than 3000 feet above the level of the sea. One summit, however, to the north of the river Ouba, has an elevation of 5691 feet. Although the Altai mountains bear different names, they range eastward as far as the ocean. The higher parts are generally bare, and the shores of the rivers which run through them are generally clothed with forests. As they extend east from the Jenesei to the Baikal sea, they assume a grander character, and are called the Sayanskoi mountains. They are chiefly naked granite rocks, sharp and abrupt, and frequented chiefly by hunters; and they determine the boundaries between Siberia and Mongolia. The mountains of Baikal have nearly the same direction as that sea, and run down to the west on the right of the Angora, where it flattens in a morasse steppe of prodigious extent. To the east, it advances from the origin of the Lena on both sides of that river, and here it is lost in a wide extended floetz ridge. In the inferior regions of the Angora and the Lena, coal is frequently produced. Several of these mountain ranges in the neighbourhood of the Baikal are so high, that they are covered with perpetual snow. The Nertshinskoi mountains, otherwise called the mountains of Daouria, extend from the lake Baikal and the sources of the Selenga and the Amour, down the two sides of these rivers; on the one side, as far as where the Argoon falls into the Amour; and on the other, or northern side, up to the sources of the Niusa and the Oldekon, where it joins the spacious range of Okhotsk. The portion of this range enclosed by the Amoor and Argoon, which is properly called the Nertshinskoi chain of mountains, is found to be the richest in minerals of any of the mountains hitherto explored in these regions; producing, amongst other sorts, zinc, iron, copper, and lead ores containing silver and gold. These mountains present, according to the descriptions of a traveller who visited them in search of the rhubarb plant, a wild scene of desolation;

thick woods, torrents and precipices, without a human habitation, except a few sheds erected by hunters when they are in pursuit of game. In approaching the eastern ocean, these mountains decline in elevation, and turning to the north, run parallel to the sea, leaving a narrow space between them. The mountains of Okhotsk run northward down the Lena to Yakutsk; one runs eastward to the sea of Okhotsk, whilst another continues its course with the peninsula of Kamtschatka, which consists of a rocky chain of mountains, about which little information has ever been acquired.

St es, wa s, mo- ras

The surface of Siberia comprises every variety of soil. The tracts which are called steppes are dry, elevated, and extensive plains, which are not inhabited, and some of them, which are uninhabitable, are destitute both of food and water. Others have shrubs growing on them or a stunted herbage, and are watered by streams or wells, though without inhabitants, and thus afford pasture to the herds and flocks of the shepherds who range over these desolate plains. In regard to the soil on these steppes, great variety prevails, none being fruitful and proper for meadow or arable land, or indiscriminately for both; in others the soil is unfruitful, whether it be sand or salt, or in some cases of a rocky formation.

Ri s.

Siberia is well watered by numerous and large rivers, an account of which may be found in the article RUSSIA. It may merely be mentioned here, that those great rivers are the Irtysch, the Obi, the Jenesei, and the Lena, which have all their sources in the frontier range of mountains, and roll onwards to the Frozen Ocean. All the other numerous rivers which rise in Siberia, are tributaries of those main rivers.

M

The cold and mountainous regions of Siberia are great depositories of those vast stores of mineral wealth by which the Russian empire is encircled. The elevated districts of this vast country abound in the most precious ores of all the different metals.

An official account of the produce of the mines of gold, silver, and platina, in Russia, has been published at St. Petersburg; it embraces a period of sixteen years, from 1823 to 1838 inclusive, and shews the following results:—

	Gold. Poods.	Silver. Poods.	Platina. Poods.
Produce of the Imperial mines—			
In Ural,	1,592½	...	29
In Altai,	538½	14,704¼	...
In Nertshinskoi,	9¾	3,301¾	...
Produce of mines belonging to individuals,	3,009¾	...	1,230
	5,150½	18,006	1,259

Value in Sterling about L.12,000,000 and L.6,000,000.

During the same period, the value of money coined at the Imperial Mint at St. Petersburg, from Russian and foreign bullion, was about L.14,000,000 in gold, L.8,000,000 in silver, and L.400,000 in platina.

Pop tion

The population of Siberia consists of numerous tribes, who differ in their origin and their manners, and have been gradually subjected to the Russian authority, paying a stated tribute, which is not oppressive, and following their own pursuits unmolested. The Mongols, who withdrew from the Chinese dominion during the last century, and voluntarily placed themselves under the dominion of Russia, inhabit the regions about the Selenga, in the government of Irkutsk, from the 122d to the 125th degree of longitude, and between the 50th and 53d degree of north latitude They consist of seven stems, or twenty families, which were estimated to compose 6918 males in 1766. The Burats inhabit Daouria, the banks of the Selenga, of the lake Baikal, and of the Upper Jenesei. They are remarkably industrious, and are chiefly employed in pastoral pursuits. The Tartars form a very numerous race, and are found scattered over Siberia, under the different appellations of Tobolskian Tartars, from the river Tobol, on which they dwell; the Tomskian Tartars, who inhabit both sides of the river Tom, above and below the city of Tomsk; the Krasnayarskian and the Kusneretskian Tartars, who greatly resemble the Mongolian tribes; the Tartars of the Obi, who are partly agricultural and partly pastoral in their habits; the Tartar tribe, which dwelt formerly between the Obi and the Jenesei, but which now inhabit the whole country along the river Tschulym; other tribes, of which it would serve little purpose to give the barbarous appellatious, inhabit the country between the Obi and the Irtysch, which is called the steppe of Baraba. There are others on the left shore of the Jenesei, upon which they follow their pastoral occupations amongst the Sayome mountains. Certain districts in the governments of Tobolsk and Kolhyvan, and partly in the eastern half of that of Perm, beyond the Ural mountains, are to be regarded as the peculiar home and seat of the Siberian Tartars. The northern districts of Siberia are possessed by twenty tribes, peculiar to itself. The principal are the Tungouses on the Jenesei, the Ostiaks, the Yakantes, the Samoiedes, and the Tchantchis. The extensive deserts on which roam the pastoral tribe of the Tungouses, extend eastward across the Lena, as far as the Amoor and the Eastern Ocean. They extend northward from the 53d to the 65th degree. The history of the Samoiedes is little known. Their present abodes are on the coasts of the Frozen Ocean, from about the 65th degree of north latitude, quite to the sea shore. They swarm up to the 75th degree of north latitude, dwelling on the coldest and most desolate regions of the earth, from the White Sea to the other side of the Jenesei, and almost up to the Lena, and, therefore, being both in Europe and in Siberia. There are the Ostiaks of the Obi, of the Narym, and of the Jenesei. The Ostiaks are not numerous; but they include many subordinate tribes, which it is unnecessary to specify by name, as they all resemble each other in manners. Giorgi gives the following statement of the population in 1801. In the government of Tobolsk, 622,422; in the government of Irkutsk, 451,937.

Religion.

The religion generally diffused amongst these wild tribes, if it deserve the name, is a rude superstition, or idolatry, congenial to the state of barbarism which generally prevails. The system of Boodh, or of the Lamas, is the creed of the Mongols and Tartars; and the residence of the Lama, the chief of that religion, is on the Upper Selenga, to the south of Baikal. The great temple was entered by a late traveller, who found there about a hundred priests, clothed in red, and seated in successive rows. The high-priest was seated upon a lofty and splendid throne, behind which was an altar, upon which were placed the images of their gods, the inferior ones being arranged in rows along the wall. Offerings were presented to them of rice, brandy, and sometimes a hen or sheep roasted whole. Their worship consists in a great measure of noise, the most formidable sounds being produced by a combination of the most noisy instruments, such as bells, kettle-drums, trumpets, shells, and other instruments. Those superstitious rites are, however, denounced by the pure followers of the genuine Lamas. They practise other vile and bloody rites, by way of expiating the anger of their gods; such as leaping, and howling in a frightful mannner, and pretending to wound their backs with knives. Amongst the rude wanderers in the northern regions of Siberia complete paganism prevails, consisting of the ignorant arts of sorcery, and the worship of deformed stone images. The light of Christianity has hardly yet penetrated into these benighted regions. By the recent enterprising and active efforts, however, of the missionary societies of Britain, aided by the countenance of the Russian government, a beginning has been made in the great work of civilizing and of converting these barbarous tribes.

Missionaries have been spread over the country; and the sacred volume has been translated into some of the native languages, and distributed amongst the natives. The greatest obstacle to their conversion arises from their brutish ignorance and their debased habits.

Commerce.

The commerce of Siberia consists in those products which are consumed at home, and of those which are exported to European Russia, in return for foreign products. The exports are chiefly metals and furs, besides those commodities from China and the East, of which Siberia is merely the dépôt in their transit to Europe The two staple commodities of export, namely, metals and furs, are chiefly monopolised by the government, to whose officers the tribute of the wandering tribes is paid in furs; and for these no return is made, unless in the salaries of the civil and military officers, or the pay of the troops.

Siberia is divided into two governments, namely, Tobolsk and Irkutsk, which are again subdivided, the former into the four circles of Tobolsk proper, Tomsk, Yeniceysk, and Kolyvan; the latter, into Irkutsk proper, Nertschink, Yakutsk, and Okhotsk, in which last is included Kamtschatka, with the islands.

SIBYLS, in pagan antiquity, certain women said to have been endowed with a prophetical spirit, and who delivered oracles, showing the fates and revolutions of kingdoms. Their number is unknown. Plato speaks of one, others of two, Pliny of three, Ælian of four, and Varro of ten; an opinion which is universally adopted by the learned. These ten Sibyls generally resided in the following places: Persia, Lybia, Delphi, Cumæ in Italy, Erythræa, Samos, Cumæ in Æolia, Marpessa on the Hellespont, Ancyra in Phrygia, and Tyburtis. The most celebrated of the Sibyls is that of Cumæ in Italy, whom some have called by the different names of Amalthæa, Demiphile, Herophile, Daphne, Manto, Phemonoe, and Deiphobe. It is said, that Apollo became enamoured of her, and that to make her sensible of his passion he offered to give her whatever she asked. The Sibyl demanded to live as many years as she had grains of sand in her hand, but unfortunately forgot to ask for the enjoyment of the health, vigour, and bloom, of which she was then in possession. She had already lived about seven hundred years when Æneas came to Italy, and, as some have imagined, she had three centuries more to live before her years were as numerous as the grains of sand which she had had in her hand. She gave Æneas instructions how to find his father in the infernal regions, and even conducted him to the entrance of hell. According to the most authentic historians of the Roman republic, one of the Sibyls came to the palace of Tarquin the Second, with nine volumes, which she offered to sell for a very high price. The monarch disregarded her, and she immediately disappeared, but soon afterwards returned, when she had burned three of the volumes. She asked the same price for the remaining six books; and when Tarquin refused to buy them, she burnt three more, and still persisted in demanding the same sum of money for the three that were left. This extraordinary behaviour astonished Tarquin; he bought the books; and the Sibyl instantly vanished, and never afterwards appeared to the world. These books were preserved with great care by the monarch, and called the Sibylline verses. A college of priests was appointed to take care of them; and such reverence did the Romans entertain for these prophetical books, that they were consulted with the greatest solemnity, when the state seemed to be in danger. When the capitol was burned in the troubles of Sylla, the Sibylline verses, which were deposited there, perished in the conflagration; and to repair the loss which the republic seemed to have sustained, commissioners were immediately sent to different parts of Greece to collect whatever verses could be found of the inspired writings of the Sibyls. The fate of these Sibylline verses, which were collected after the conflagration of the capitol, is unknown. There are now many Sibylline verses extant, but they are universally reckoned spurious; and it is evident that they were composed in the second century by some of the followers of Christianity, who wished to convince the heathens of their error, by assisting the cause of truth with the arms of pious artifice.

SICERA, a name given to any inebriating liquor by the Hellenistic Jews. St. Chrysostom, Theodoret, and Theophilus of Antioch, who were Syrians, and who therefore ought to know the signification and nature of sicera, assure us, that it properly signifies palm-wine.

SICILIANA, the name of an ancient dance in $\frac{6}{8}$ time, slow in movement, and simple and touching in its melody.

SICILY, a large island in the Mediterranean Sea, adjoining to the southern extremity of Italy, and extending from latitude 36° 25′ to latitude 38° 25′, and from longitude 12° 50′ to longitude 15° 40′ east from London. Its greatest length is 210 miles, its breadth 133, its circumference 600. For a description of the island, see NAPLES.

SIDDONS, MRS. (whose maiden name was Sarah Kemble,) the greatest actress that ever trode the stage, was born at Brecon, in South Wales, on the 5th of July 1755. Roger Kemble, her father, was manager of a provincial company of players, and amongst this class of persons he seems to have held a highly respectable rank. Sarah, who was his eldest daughter, appeared very early on the stage, and went the usual round of juvenile characters without exciting much expectation. At the age of eighteen she married Mr. Siddons, an actor in her father's company, soon after which event she removed to Cheltenham, where she attracted some attention, and was recommended to Garrick. Her first appearance on the London boards was not successful, simply because she never had a proper part assigned her. Mrs. Siddons accordingly returned to the provinces much mortified; but the praises showered upon her by such audiences as those of York, Manchester, and Bath, induced the managers of Drury Lane to re-invite her to the metropolis. Her reappearance took place on the 10th of October 1782. The character which she chose was that of Isabella in "The Fatal Marriage." The effect of that performance was extraordinary and unparalleled. It gave a shock of wonder and delight to the public mind, like the news of some great and unexpected victory. On that night, Mrs. Siddons at once took possession of the tragic throne, on which, for thirty years, she reigned without a rival. Some idea of the excitement which she created may be learned from the fact, that "the grave and reverend seignors" of the English bar presented her with a purse of one hundred guineas. During the season, Mrs. Siddons played *Euphrasia*, *Jane Shore*, *Calista*, and, for her two benefits, *Belvidera* and *Zara*. In all of these characters she greatly added to her fame; the public were astonished at the vastness of her powers, and tragedy became the fashion. In subsequent seasons she encreased her circle of characters, adding from Shakespeare those of *Lady Macbeth*, *Constance*, *Isabella*, *Queen Katherine*, (the most chaste, beautiful, and perfect performance that ever drew a tear,) *Rosalind*, (not in her line, for she was altogether too stately and heroic for comedy,) *Desdemona*, *Volumnia*, *Portia*, *Hermione*, *Imogene*, and a few others. This list shows, that her range was surprising, but she was not equally excellent in all her parts. Her comedy never gave great satisfaction, although there was occasionally much to admire in it. When the metropolitan season closed, it was the custom of this, as it is of every great actor, to visit the principal cities of Ireland, Scotland, and the provinces of England. Every where she enchanted the lovers of the drama. She became a favourite with their majesties, and was in the habit of reading plays to them, an occupation of more honour than emolument. However, Mrs. Siddons, by her professional exertions, realized a for-time equal to her wishes, and retired from the stage in 1812. Her death took place on the 8th of June 1831, when she was in her 76th year.

The symmetry of this great actress's person was most captivating. Her features were strongly marked, but finely harmonised; the flexibility of her countenance was extraordinary, yielding instantaneously to every change of passion; her voice was plaintive, yet capable of firmness and exertion; her articulation was clear, penetrating, and distinct;—above all, she was completely mistress of her powers, and possessed that high judgment which enabled her to display all her other qualifications to the greatest advantage. One of Mrs. Siddons's highest, if not her very highest endowment, was the power of identifying herself with the character which she personated. The scenes in which she acted, were to her far from being a mere mimic show; so powerfully did her imagination conjure up the reality, that the tears which she shed were those of bitterness felt at the moment. From her frown of proud disdain and scorn, the very actors themselves shrank with something like terror. Her greatest characters were Katherine in Henry VIII., and Lady Macbeth, in which she manifested a dignity and a sensibility, a power and a pathos never equalled by any female performer. Lastly, Mrs. Siddons was truly an original; she copied no one, living or dead, but acted from nature and herself. In all the relations of life her conduct was most exemplary. "She was more than a woman of genius," says the poet Campbell, who knew her well, "for the additional benevolence of her heart made her an honour to her sex, and to human nature." (R.R.R.)

SIDMOUTH, a town of the hundred of East Budleigh, in the county of Devon, 159 miles from London, The population was, in 1821, 2747; and in 1831, 3126.

SIDNEY, Sir Philip, was born, as is supposed, at Penshurst in Kent, in the year 1544. His father was Sir Henry Sidney, an Irish gentleman, and his mother, Mary, the eldest daughter of John Dudley, Duke of Northumberland. He was sent, when very young, to Christ-Church College at Oxford, but left the university at seventeen to set out on his travels. After visiting France, Germany, Hungary, and Italy, he returned to England in 1575, and was next year sent by Queen Elizabeth, as her ambassador to Rodolph, the Emperor of Germany. On his return he visited Don John of Austria, governor of the Netherlands, by whom he was received with great respect. In 1579, when Queen Elizabeth seemed on the point of concluding her long projected marriage with the Duke of Anjou, Sir Philip wrote her a letter, in which he dissuaded her from the match with unusual elegance of expression, and great force of reasoning. About this time a quarrel with the Earl of Oxford occasioned his withdrawing from court; during which retirement he is supposed to have written his celebrated romance called Arcadia.

In 1585, after the Queen's treaty with the United States, he was made governor of Flushing and master of the horse. Here he distinguished himself so much both by his courage and his conduct, that his reputation rose to the highest pitch. He was named, it is said, by the republic of Poland as one of the competitors for that crown, and might even have been elected, had it not been for the interference of the queen. But his illustrious career was soon terminated; for being wounded at the battle of Zutphen, he was carried to Arnheim, where he died on the 15th of October 1586. His body was brought to London, and buried in St. Paul's cathedral. He is described, by the writers of that age, as the most perfect model of an accomplished gentleman that could be formed even by the wanton imagination of poetry or of fiction. Virtuous conduct, polite conversation, heroic valour, and elegant erudition, all concurred to render him the ornament and delight of the English court; and as the credit which he enjoyed with the queen and the Earl of Leicester was wholly employed in the encouragement of genius and literature, his praises have been transmitted with advantage to posterity. No person was so low as not to become an object of his humanity. After the battle of Zutphen, whilst he was lying on the field mangled with wounds, water was brought him to relieve his thirst; but observing a soldier in a like miserable condition, looking wistfully towards him, he resigned it to him, saying, "This man's necessity is still greater than mine." Besides his Arcadia, he wrote a discourse on Poetry, and some other pieces both in prose and verse, which have been published. There is a complete edition of his works in three volumes octavo, Lond. 1725.

Sidney, *Algernon*, was the second son of Robert Earl of Leicester, and Dorothy, eldest daughter of the Earl of Northumberland. He was born in 1617. During the civil wars he took part against the king, and distinguished himself as a colonel in the army of the parliament. He was afterwards appointed one of King Charles's judges, but declined appearing in that court. During the usurpation of Cromwell, Sidney, who was a violent republican, retired to the country, and spent his time in writing those discourses on government which have been so deservedly celebrated. After the death of the Protector, he again took part in the public transactions of his country, and was abroad on an embassy to Denmark when Charles was restored. Upon this he retired to Hamburg, and afterwards to Frankfort, where he resided till 1677, when he returned to England and obtained from the king a pardon. It has been affirmed, but the story deserves no credit, that, during his residence abroad, Charles hired ruffians to assassinate him. After his return he made repeated attempts to procure a seat in parliament, but all of them proved unsuccessful. After the intention of the Commons to exclude the Duke of York from the throne had been defeated by the sudden dissolution of parliament, Sidney joined with eagerness the councils of Russel, Essex, and Monmouth, who had resolved to oppose the duke's succession by force of arms. Frequent meetings were held at London; whilst at the same time, a set of subordinate conspirators, who were not, however, admitted into their confidence, met and embraced the most desperate resolutions. Keiling, one of these men, discovered the whole conspiracy; and Algernon Sidney, together with his noble associates, was immediately thrown into prison, and no art was left unattempted to involve them in the guilt of the meanest conspirators.

Howard, an abandoned nobleman, without a single spark of virtue or honour, was the only witness against Sidney; but as the law required two, his discourses on government, found unpublished in his closet, were construed into treason, and declared equivalent to another witness. It was in vain for Sidney to plead that papers were no legal evidence; that it could not be proved they were written by him; and that if they were, they contained nothing treasonable. The defence was overruled; he was declared guilty, condemned, and executed on Towerhill, December 7, 1678. His attainder was reversed in the first year of William III.

He was a man of extraordinary courage, steady even to obstinacy, and of a sincere but rough and boisterous temper. Though he professed his belief in the Christian religion, he was an enemy to an established church, and even, according to Burnet, to every kind of public worship. In his principles he was a zealous republican. Government was always his favourite study; and his essays on that subject are a proof of the progress which he made. His Treatise on Government, and some other pieces, with memoirs of his life, were published by Thomas Holles, in 1763, in a quarto volume.

SIDON, in *Ancient Geography* a city of Phœnicia in Asia, famous in Scripture for its riches, arising from the extensive commerce carried on by its inhabitants. Heavy judgments were denounced against the Sidonians on account of their wickedness, which were accomplished in the time of Ochus king of Persia. That monarch having come against them with an army on account of their rebellion, the city was betrayed by its king; upon which the wretched inhabitants, seized with despair, set fire to their houses, and forty thousand, with their wives and children, perished in the flames. It is forty-five miles west from Damascus. E. long. 36. 5. N. lat. 37.

SIDUS, GEORGIUM, in *Astronomy*, a new primary planet, discovered by Dr. Herschel in the year 1781. By most foreign, and even by some British philosophers, it is known by the name of *Herschel*, in honour of the discoverer. As the other planets are distinguished by marks or characters, the planet Herschel is distinguished by an H, the initial letter of the discoverer's name, and a cross to shew that it is a Christian planet.

SIEBENBURGEN. See TRANSYLVANIA.

SIENNA, or SIENA, a district of Italy, still called a duchy, though now a part of the grand duchy of Tuscany. It is mostly situated on the Apennines, and was an independent state, till it was subdued and united with Tuscany in 1557. The capital is the city of that name, on the great road from Florence to Rome. It is surrounded with walls, and, when approached from Rome, has a magnificent appearance, but, on the side towards Florence, the view of it is hidden by woods and gardens. The city is old and rather ill built, but it contains many fine palaces belonging to noble families. It is the see of an archbishop, the cathedral, 330 feet in length, is celebrated for its fine cupola. There is a spacious market-place, with a council house and theatre, that are ornamental. It contains twenty-three churches, several of which are adorned with the finest paintings in fresco. The university, founded in 1321, once enjoyed the greatest fame of any in Italy, but at present has not more than two hundred and sixty students, though it still retains its museum, an anatomical theatre, a library, and other similar institutions. Its manufactures are a few woollen cloths, hats, strings for musical instruments, paper, and objects formed of marble or of ivory. Its population is 24,500 persons. Lat. 43. 22. Long. 11. 5. E.

SIERRA LEONE, a colony of Great Britain, situated on the western coast of Africa. Lat. 8. 10. Long. 12. 30. It is a peninsula, bounded on the north by the river called Sierra Leone, on the south and west by the sea at Calmont creek, and on the east by a line up the Calmont to the Watslod creek, and down this last to the Dunce, which is indeed a part of the Sierra Leone river. These boundaries enclose a tract of country extending eighteen miles from north to south, and twelve miles from east to west; but there is an additional tract of country adjoining Sierra Leone, which was ceded to Great Britain by an African chief in 1819. Sierra Leone, as its name indicates, is a mountainous tract of country, but with numerous intervening valleys. The heights are covered to their summit with lofty forests, giving to the distant scenery a rich and romantic appearance. The territory on the north side of the river is, however, low and level. Numerous streams descend from the hills, which collect into a basin called the Bay of Franca, celebrated as a watering-place. The Sierra Leone is more of an estuary than a river; it is twenty miles in length, by ten in breadth, at its mouth. The Rokelle affords a water communication for some distance into the interior. The range of the thermometer at Sierra Leone is very slight, and the average heat throughout the year is 82°. The rains continue for six months, and the torrents which descend from the mountains deluge the plains beneath. The mountains in the vicinity of Free Town, the capital, have now been cleared and cultivated, which has greatly added to the salubrity of the climate. Indeed, the settlement is now stated in the medical reports to be as healthy for Europeans as any other tropical country, so that it is no longer the pestiferous charnel-house which it was formerly considered. The edible fruits of Sierra Leone are numerous and luscious, including pine apples, superior in flavour to those cultivated in England; the baobab, or monkey bread, a valuable tree; oranges, plantains, bananas, limes, and many others. The country is prolific in various precious products of the soil, besides fruits. The animal kingdom is very abundant, comprising many species of antelopes, monkeys, and other denizens of a tropical country.

Free Town, the capital of the colony, is built upon the south side of the Sierra Leone river, and at the northern extremity of the peninsula. Immediately in front of the town, the river forms a bay, where there is good and commodious anchorage for vessels of all classes, and timber ships of considerable size proceed with facility nearly twenty miles higher up the stream, for the purpose of taking in their cargoes. The town is beautifully situated on an inclined plane, at the foot of some hills, on which stand the fort and other public buildings, that overlook it and the roads; whence there is a fine prospect of the town rising in the form of an amphitheatre from the water's edge, above which it is elevated seventy feet. It is regularly laid out into streets, stretching three quarters of a mile in length, intersected by others at right angles, and parallel with the river. The buildings are commodious, and substantially built of stone, which at once contribute to the beauty of the place, and to the health and comfort of the inhabitants. Numbers of cocoa-nut, orange, lime, and banana trees, are dispersed all over the town, imparting to it a peculiarly picturesque appearance. The Madeira and Teneriffe vines flourish well in the gardens. Nearly all our garden vegetables are raised there; and what with yams, cassada, and pompions, there is rarely any want of vegetable products for the table. There are good meat, poultry, and fish markets; and almost every article of housekeeping can be procured at the shops of the British merchants. The population of the capital may be estimated at 10,000.

Throughout the peninsula, several villages have been formed, viz., Leicester, founded in 1809; Regent, in 1812; Gloucester, in 1816; Kissey and Leopold, in 1817; Charlotte, Wilberforce, and Bothwell, in 1818; Kent, York, Wellington, and Waterloo, in 1819. These villages are generally situated in different parts of the mountain, but all are connected by good roads with each other, and with the capital. The two Banana islands, situated to the south-west of Free Town, were ceded to the British government in 1819, by a family who receive an annual payment for them. The total population of Sierra Leone is about 35,000, of whom not more than 200 are Europeans; the remainder are captured or liberated slaves, or their descendants, together with some native Africans. Many of the colonists, besides the Europeans, possess considerable wealth. The total number of slaves emancipated in Sierra Leone, between June 1819 and January 1833, was 27,697. Some of these, no doubt, retain their habits of indolence, but in general the freed African relishes liberty, and is grateful for the boon conferred on him, and several, by their industry and economy, are said to have acquired property amounting to L.1000 sterling. There are public schools in each parish, and from 3000 to 4000 children attend them. A large portion of the colony are enjoying, and all have access to, the means of moral and religious instruction. Upwards of one-fourth are regular attendants on the public ordinances of religion. They have built for themselves various and expensive places of worship; some of them are employed as spiritual instructors of their sable brethren; and all together, considering its circumstances, this negro colony is composed of an orderly and well-conducted people. Agriculture has not, indeed, been sufficiently prosecuted hitherto, but matters will improve in this respect when population increases, and presses upon the means of supply. The soil is in part very fertile, and more might be rendered so by clearing.

The trade of this settlement is as follows: For the year ending December 1834, there cleared inwards seventy-three vessels, whose united tonnage was 17,307. Fifty-four of these belonged to Great Britain. The number which cleared outwards during the same period was eighty-four, the tonnage of the whole being 19,068. This shows an increase on the previous year. The total value of the imports for 1831, were L.104,639; and of the exports L.81,280. Subsequent returns for 1833-4, show a decrease, which does not correspond with the number of vessels which arrived at, and departed from the settlement. The chief articles of export are timber, cam wood, palm oil, ivory, rice, bees' wax, gold, hides, &c. In 1835, these were exported to the extent of L.58,174. The chief articles imported into Sierra Leone, are cottons, gunpowder, linens, salt, guns, iron, hard-wares, and cutlery, and others of our own manufactures. This settlement is kept up at a considerable yearly expenditure. For the five years ending 1824, it was L.75,000 per annum; for the succeeding five years, it fell to about one-half that sum; but still the revenue bears no proportion to the outlay. Sierra Leone is governed by a civil-lieutenant governor, assisted by a council. There is a chief-justice, and a vice-court of admiralty. There is also established, the mixed commission for the adjudication of vessels taken in the slave-trade. A detachment of the Royal African corps (blacks) is stationed in the settlement, under a lieutenant-colonel.

This colony was founded by Great Britain with the most philanthropic views. At the suggestion of Dr. Smeathmane, the negroes discharged from the army and navy, after the American war, were conveyed to Sierra Leone, furnished with necessaries for forming a colony in their native land. But a series of calamities overtook this singularly interesting band of settlers, which obliged those who escaped pestilence and the sword to take shelter on Bance island, a small place. However, the Sierra Leone Company was formed in Britain in 1787, and it sent out five vessels with stores, and other succours, to these black freemen, together with a large reinforcement of free negroes from America. Still the difficulties with which the colony had to struggle, again placed it in critical circumstances, whilst in 1794, it was plundered by the French; and so much had calamities accumulated, that the company entered into an arrangement with the government, to place the colony under their jurisdiction. It was subsequently placed under the African Institution, established for the improvement of the western part of Africa. Great accessions were made to its population, by sending thither the negroes taken in slave ships, and to initiate them in the habits of civilized life; the Church Missionary Society undertook to furnish schools and religious instructors. But the success of this body has not been equal to its benevolent intentions, at least with regard to other parts of Africa, little or no impression having as yet been made on the general mass of the population from this quarter. Since the dissolution of the African Company, Sierra Leone has again reverted to the British crown.

SIERRA-MORENA, a range of remarkable mountains in the south of Spain. These mountains begin in the vicinity of Alcaraz, on the eastern borders of La Mancha, and extend between that province, Estremadura, and Alentejo, which it leaves to the north, and enters the kingdoms of Jaen, Cordova, Seville, and Algarve, and terminates at the sea shore at Cape St. Vincent. In its course through Cordova, it is called the Sierra de Cordova. On the south of Estremadura, and the north of Seville, it bears the name of the Guadalcanal mountains; it then trends to the south-west, where the northern side is called the Sierra of Calderion; on the south, in the Portuguese province of Algarve, it is called the Sierre de Monchique.

The highest point of these mountains does not exceed 2700 feet above the level of the sea; but from their summits being barren, and the lower parts mere morasses, they were long deemed impassable, and were so deemed at the period when the author of Don Quixote chose them for the scene of the exploits of his hero.

In the late war with France, a pass through them was deemed by the Spaniards to be impregnable, but the French troops were adroit enough to turn them, and thus were enabled to pour their armies into Andalusia, and besiege Cadiz.

After the peace of 1763, king Charles the III. entertained the project of cultivating this district; and Olavide, a benevolent and enterprising capitalist, transported thither a number of Germans, who were formed into colonies, and built several villages, and the town of Carolina. The face of the country was changed, and the soil found productive; the progress was advancing, when Olavide was involved in difficulties with the Inquisition, which gave a check to the operations, which the hostile operations carried on at subsequent periods have continued.

SIEUR, a title of respect amongst the French, like that of *master* amongst us. It is much used by lawyers, as also by superiors in their letters to inferiors.

SIFANTO, or SIPHANTO, an island of the Archipelago, west of Paros, north-east of Milo, and south-west of Serphanto. The air is so good here, that many of the inhabitants live to the age of a hundred and twenty; and their water, fruits, wild fowl, and poultry, are excellent, but more especially the grapes. It abounds with marble and granite, and is one of the most fertile and best cultivated of these islands. The inhabitants employ themselves in cultivating olive-trees and capers; and they have very good silk. They trade in figs, onions, wax, honey, and straw-hats, and may be about eight thousand in all. E. Long. 25. 15. N. Lat. 37. 9.

SIGHING, an effort of nature, by which the lungs are put into greater motion, and more dilated, so that the blood passes more freely, and in greater quantity, to the left auricle, and thence to the ventricle. Hence we learn how sighing increases the force of the blood, and proportionally cheers and relieves nature, when oppressed by its too slow motion, which is the case of those who are dejected and sad.

SIGNALS, NAVAL. When we read at our fire-side the account of an engagement, or other interesting operation of an army, our attention is generally so much engaged by the results, that we give but little to the movements which led to them, and produced them; and we seldom form to ourselves any distinct notion of the conduct of the day. But a professional man, or one accustomed to reflection, and who is not satisfied with the mere indulgence of eager curiosity, follows every regiment in its movements, endeavours to see their connection, and the influence which they have had on the fate of the day, and even to form to himself a general notion of the whole scene of action, at its different interesting periods. He looks with the eye of the general, and sees his orders succeed or fail.

But few trouble themselves farther about the narration. The movement is ordered; it is performed; and the fortune of the day is determined. Few think how all this is brought about; and when they are told that during the whole of the battle of Custrin, Frederick the Great was in the upper room of a country inn, whence he could view the whole field, whilst his aides-de-camp, on horseback, waited his orders in the yard below, they are struck with wonder, and can hardly conceive how it can be done, but, on reflection, they see the possibility of the thing. Their imagination accompanies the messenger from the inn yard to the scene of action; they hear the general's orders delivered, and they expect its execution.

But when we think for a moment on the situation of the commander of a fleet, confined on board one ship, and this ship as much, or more closely, engaged, than any other of the fleet; and when we reflect that here are no messengers ready to carry his orders to ships of the squadron at the distance of miles from him, and to deliver them with precision and distinctness, and that even if this were possible by sending small ships or boats, the vicissitudes of wind and weather may render the communication so tedious, that the favourable moment may be irretrievably lost before the order can be conveyed. When we think of all these circumstances, our thoughts are bewildered, and we are ready to imagine that a sea battle is nothing but the unconnected struggle of individual ships; and that when the admiral has once "cried havoc, and let slip the dogs of war," he has done all that his situation empowers him to do, and he must leave the fate of the day to the bravery and skill of his captains and sailors.

Signals a language to the eye.

Yet it is in this situation, apparently the most unfavourable, that the orders of the commander can be conveyed, with a dispatch that is not attainable in the operations of a land army. The scene of action is unincumbered, so that the eye of the general can behold the whole without interruption. The movements which it is possible to execute, are few, and they are precise. A few words are sufficient to order them, and then the mere fighting the ships must always be left to their respective commanders. This simplicity in the duty to be performed has enabled us to frame a language fully adequate to the business in hand, by which a correspondence can be kept up as far as the eye can see. This is the language of *signals*, a language by writing, addressed to the eye, and which he that runneth may read. As in common writing certain arbitrary marks are agreed on to express certain sounds used in speech, or rather, as in hieroglyphics, certain arbitrary marks are agreed on to express certain thoughts, or the subjects of these thoughts; so here certain exhibitions are made, which are agreed on to express certain movements to be executed by the commander to whom they are addressed, and all are enjoined to keep their eyes fixed on the ship of the conductor of the fleet, that they may learn his will.

It was so in ancient times.

It is scarcely possible for any number of ships to act in concert, without some such mode of communication between the general and the commanders of private ships. We have no direct information of this circumstance in the naval tactics of the ancient nations, the Greeks and Romans; yet the necessity of the thing is so apparent, that we cannot suppose it to have been omitted by the most ingenious and the most cultivated people who have appeared on the great theatre of the world; and we are persuaded that Themistocles, Conon, and other renowned naval commanders of Athens, had signals by which they directed the movements of their fleets. We read, that when Ægeus sent his son Theseus to Crete, it was agreed on, that if the ship should bring the young prince back in safety, a white flag should be displayed. But those on board, in their joy for revisiting their country after their perilous voyage, forgot to hoist the concerted signal. The anxious father was every day expecting the ship which should bring back his darling son, and had gone to the shore to look out for her. He saw her, but without the signal agreed on; on which the old man threw himself into the sea. We find, too, in the history of the Punic wars by Polybius, frequent allusions to such a mode of communication; and Ammianus Marcellinus speaks of the *speculatores* and *vexillarii*, who were on board the ships in the Adriatic. The coins both of Greece and Rome exhibit both flags and streamers. In short, we cannot doubt of the ancients having practised this hieroglyphical language. It is somewhat surprising that Lord Dudley, in his *Arcano del Mare*, in which he makes an ostentatious display of his knowledge of every thing connected with the naval service, makes no express mention of this very essential piece of knowledge, although he must, by his long residence in Italy, have known the marine discipline of the Venetians and Genoese, the greatest maritime powers then in Europe.

Also in modern times.

In the naval occurrences of modern Europe, mention is frequently made of signals. Indeed, as we have already observed, it seems impossible for a number of ships to act in any kind of concert, without some method of communication. Numberless situations must occur, when it would be impossible to convey orders or information by messengers from one ship to another, and coast and alarm signals had long been practised by every nation. The idea, therefore, was familiar. We find, in particular, that Queen Elizabeth, on occasion of the expedition to Cadiz, ordered her secretaries to draw up instructions, which were to be communicated to the admiral, the general, and the five counsellors of war, and by them to be copied and transmitted to the several ships of the navy, not to be opened till they should arrive in a certain latitude. It was on this occasion, says our historian Guthrie, "that we meet with the first regular sets of signals and orders to the commanders of the English fleet." But till the movements of a fleet have attained some sort of uniformity, regulated and connected by some principles of propriety, and agreed on by persons in the habit of directing a number of ships, we may with confidence affirm that signals would be nothing but a parcel of arbitrary marks, appropriated to particular pieces of naval service, such as attacking the enemy, landing the soldiers, and the like; and that they would be considered merely as referring to the final result, but by no means pointing out the mode of execution, or directing the movements which were necessary for performing it.

First for ed into a system b James I when Du of York.

It was James II. when Duke of York, who first considered this practice as capable of being reduced into a system, and who saw the importance of such a composition. He, as well as the king his brother, had always showed a great predilection for the naval service; and when appointed admiral of England, he turned his whole attention to its improvement. He had studied the art of war under Turenne, not as a pastime, but as a science, and was a favourite pupil of that most accomplished general. Turenne one day pointed him out, saying, "Behold one who will be one of the first princes and greatest generals of Europe." When admiral of England, he endeavoured to introduce into the maritime service all those principles of concert and arrangement which made a number of individual regiments and squadrons compose a great army. When he commanded in the Dutch war, he found a fleet to be little better than a collection of ships, on board of each of which the commander and his ship's company did their best to annoy the enemy, but with very little dependence on each other, or on the orders of the general; and in the different actions which the English fleet had with the Dutch, everything was confusion as soon as the battle began. It is remarkable that the famous pensionary De Witt, who from a statesman became a navigator and a great sea commander in a few weeks, made the same representation to the States General on his return from his first campaign.

In the memoirs of James II. written by himself, we have the following passage: "1665. On the 15th of March, the Duke of York went to Gunfleet, the general rendezvous of the fleet, and hastened their equipment. He ordered all the flag officers on board with him every morning, to agree on the order of battle and rank. In former battles, no order was kept, and this under the Duke of York, was the first in which fighting in a line and regular form of a battle was observed." This must be considered as full authority for giving the Duke of York the honour of the invention. For whatever faults may be laid to the charge of this unfortunate prince, his word and honour stand unimpeached. And we are anxious to vindicate his claim to it, because our neighbours the French, as usual, would take the merit of this invention, and of the whole of naval tactics, to themselves. True it is, that Colbert, the great and justly celebrated minister of Louis XIV. created a navy for his ambitious and vain-glorious master, and gave it a constitution which may be a model for other nations to copy. By his encouragement, men of the greatest scientific eminence were engaged to contribute to its improvement; and they gave us the first treatises of naval evolutions. But it must ever be remembered, that our accomplished, though misguided sovereign, was then residing at the court of Louis; that he had formerly acted in concert with the French as a commander and flag officer, and was at this very time aiding them with his knowledge of nautical affairs. In the memorable day at La Hogue, the gallant Russel, observing one of Tourville's movements, exclaimed, "There, they have got Pepys[1] amongst them." This anecdote we give on the authority of a friend, who heard an old and respectable officer, Admiral Clinton, say, that he had it from a gentleman who was in the action, and heard the words spoken; and we trust that our readers will not be displeased at having this matter of general opinion established on some good grounds.

It was on this occasion, then, that the Duke of York made the movements and evolutions of a fleet the object of his particular study, reduced them to a system, and composed that System of Sailing and Fighting Instructions, which has ever since been considered as the code of discipline for the British navy, and which has been adopted by our rivals and neighbours as the foundation of their naval tactics. It does great honour to its author, although its merit will not appear very eminent to a careless surveyor, on account of the very simplicity which constitutes its chief excellence. It is unquestionably the result of much sagacious reflection and painful combination of innumerable circumstances, all of which have their influence; and it is remarkable, that although succeeding commanders have improved the subject by several subordinate additions, no change has to this day been made in its general principles or maxims of evolution.

Till some such code be established, it is evident that signals can be nothing but arbitrary and unconnected hieroglyphics, to be learned by rote, and retained by memory, without any exercise of the judgment; and the acquisition of this branch of nautical skill must be a more irksome task than that of learning the Chinese writing. But such a code being once settled, the character in which it may be expressed becomes a matter of rational discussion.

Accordingly, the sailing and fighting instructions of the Duke of York were accompanied by a set of signals for directing the chief or most frequent movements of the fleet. These also were contrived with so much judgment, and such attention to distinctness, simplicity, and propriety, that there has hardly been any change found necessary; and they are still retained in the British navy as the usual signals in all cases when we are not anxious to conceal our movements from an enemy.

Notwithstanding this acknowledged merit of the Duke of York's signals, it must be admitted that great improvements have been made on this subject, considered as an art. The art military has, in the course of a century past, become almost an appropriate calling, and has therefore been made the peculiar study of its professors. Our rivals the French were sooner and more formally placed in this situation; and the ministers of Louis XIV. took infinite and most judicious pains to make their military men superior to all others by their academical education. A more scientific turn was given to their education, and the assistance of scientific men was liberally given them; and all the nations of Europe must acknowledge some obligations to them for information on everything connected with the art of war. They have attended very much to this subject, have greatly improved it, and have even introduced a new principle into the art; and by this means have reduced it to the most simple form of reference to the code of sailing and fighting instructions, by making the signals immediately expressive, not of orders, but of simple numbers. These numbers being prefixed to the various articles of the code of instructions, the officer who sees a signal thrown out by the admiral, reads the number and reports it to his captain, perhaps without knowing to what it relates. Thus simplicity and secrecy, with an unlimited power of variation, are combined. We believe that M. de la Bourdonnais, a brave and intelligent officer, during the war 1758, was the author of this ingenious thought.

We do not propose to give a system of British signals. This would evidently be improper. But we shall show our readers the practicability of this curious language, the extent to which it may be carried, and the methods which may be practised in accomplishing this purpose. This may make it an object of attention to scientific men, who can improve it; and the young officer will not only be able to read the orders of the commander-in-chief, but will not be at a loss, should circumstances place him in a situation where he must issue orders to others.

Signals may be divided into,

I. Day Signals.
II. Night Signals; and,
III. Signals in a Fog.

They must also be distinguished into, First, Signals of Evolution, addressed to the whole Fleet, or to Squadrons of the fleet, or to Divisions of these squadrons; secondly, Signals of Movements to be made by particular ships; and, thirdly, Signals of Service, which may be either general or particular.

During an engagement the signals of the admiral are repeated by frigates stationed out of the line.

The great extent of a large fleet, the smoke in time of battle, and the situation of the commander-in-chief, who is commonly in the midst of the greatest confusion and hottest fire, frequently makes it very difficult for the officers of distant ships to perceive his signals with distinctness. Frigates, therefore, are stationed out of the line, to windward or to leeward, whose sole office it is to observe the admiral's signals, and instantly to repeat them. The eyes of all the signal officers in the private ships of war are directed to the repeating frigates, as well as to the admiral; and the officers of the repeating frigate, having no other duty, observe the admiral incessantly, and, being unembarrassed by the action, can display the signal with deliberation, so that it may be very distinctly seen. Being minutely acquainted with the substitutions which must be made on board the admiral when his masts and rigging are in disorder, his perhaps imperfect signal is exhibited by the repeating frigate in its proper form, so as to be easily understood. And to facilitate this communication, the commanders of the different squadrons repeat the signals of the commander-in-chief, and the commanders of division repeat the signals of the commanders of their squadron.

Evolution signals are preceded by a signal of advertisement, and accompanied with a directive signal.

Every evolution signal is preceded by a signal of advertisement and preparation, which is general, and frequently by a gun, to call attention; and when all the signals have been made which direct the different parts of that evolution, another signal is made, which marks the close of the complex signal, and divides it from others which may immediately follow it: And as the orders of the commander-in-chief may relate either to the movements of the whole fleet, those of a single division, or those of certain private ships, the Executive Signal, which dictates the particular movement, is accompanied by a Directive Signal, by which these ships are pointed out, to which the order is addressed.

Answered by the commander.

The commander of a ship to which any signal is addressed, is generally required to signify by a signal, which is general, that he has observed it. And if he does not thoroughly understand its meaning, he intimates this by another general signal. And here it is to be observed, that as soon as the signal is answered by the ships to which it is addressed, it is usual to haul it down, to avoid the confusion which might arise from others being hoisted in the same place. The order remains till executed, notwithstanding that the signal is hauled down.

---

[1] Pepys was secretary to the Duke of York.

Annulling signals.

It may happen that the commander who throws out the signal for any piece of service, sees reasons for altering his plan. He intimates this by a general annulling signal, accompanying the signal already given. This will frequently be more simple than to make the signals for the movements which would be required for re-establishing the ships in their former situation.

All these things are of very easy comprehension, and require little thought for their contrivance. But when we come to the particular evolutions and movements, and to combine these with the circumstances of situation in which the fleet may be at the time, it is evident that much reflection is necessary for framing a body of signals which may be easily exhibited, distinctly perceived and well understood, with little risk of being mistaken one for another. We shall take notice of the circumstances which chiefly contribute to give them these qualities as we proceed in describing their different classes.

I. *Of Day Signals.*

These are made by means of signals of different colours; but before we proceed to the description of the signals by means of colours, such as flags, banners, or triangular flags, pendants, or vanes, we must take notice of the ostensible distinctions of the various divisions and subdivisions of a fleet, so that we may understand how the same signal may be addressed to a squadron, division, or single ship or ships. We suppose it known that a fleet of ships of war is distributed into three grand divisions, which we shall term squadrons, called the van, centre, and rear. These denominations have not always a relation to the one being more advanced than the other, either towards the enemy or in the direction of their course.

Meaning of the terms van, centre, and rear, in the line of battle at sea.

In a land army, the position of every part is conceived from its reference to the enemy; and the reader, conceiving himself as facing the enemy, easily understands the terms van, centre, and rear, the right and left wing, and so forth. But the movements of a sea army having a necessary dependence on the wind, they cannot be comprehended unless expressed in a language which keeps this circumstance continually in view. The simplest and most easily conceived disposition of a fleet, is that in which it is almost indispensably obliged to form in order to engage an enemy. This is a straight line, each ship directly ahead of its neighbour, and close-hauled. This is therefore called the line of battle. In this position, the two extremities of the fleet correspond to the right and left wings of an army. Suppose this line to be in the direction east and west, the wind blowing from the north-north-west, and therefore the fleet on the starboard tack; the ships' heads are to the west, and the westermost division is undoubtedly the van of the fleet, and the eastermost division is the rear. And it is in conformity to this arrangement and situation that the list of the fleet is drawn up. But the ships may be on the same east and west line, close-hauled, with their heads to the west, but the wind blowing from the south-south-west. They must therefore be on the larboard tack. The same ships, and the same division, are still, in fact, the van of the fleet. But suppose the ships' heads to be to the eastward, and that they are close-hauled, having the wind from the south-south-east or the north-north-east, the ships which were the real van on both tacks in the former situation, are now, in fact, the rear on both tacks; yet they retain the denomination of the van squadron of this fleet, and are under the immediate direction of the officer of the second rank, while the other extremity is under the direction of the third officer. This subordination therefore is rather an arrangement of rank and precedence than of evolution. It is, however, considered as the natural order to which the general signals must be accommodated. For this reason, the division which is denominated van in the list of this fleet, is generally made to lead the fleet when in the line of battle on the starboard tack, and to form the weathermost column in the order of sailing in columns; and, in general, it occupies that station from which it can most easily pass into the place of the leading division on the starboard line of battle ahead. Although this is a technical nicety of language, and may frequently puzzle a landsman in reading an account of naval operations, the reflecting and intelligent reader will see the propriety of retaining this mode of conceiving the subordinate arrangement of a fleet, and will comprehend the employment of the signals which are necessary for re-establishing this arrangement, or directing the movements while another arrangement is retained.

How s- nals an dressed each of these sions.

This being understood, it is easy to contrive various methods of distinguishing every ship by the place which she occupies in the fleet, both with respect to the whole line, with respect to the particular squadron, the particular division of that squadron, and the particular place in that division. This may be done by a combination of the position and colour of the pendants and vanes of each ship. Thus the colour of the pendants may indicate the squadron, their position or mast on which they are hoisted may mark the division of that squadron, and a distinguishing vane may mark the place of the private ship in her own division. The advantages attending this method are many. In a large fleet it would hardly be possible for the commander-in-chief to find a sufficient variety of single signals to mark the ship to which an order is addressed, by hoisting it along with the signal appropriated to the intended movement. But by this contrivance one-third part of these signals of address is sufficient. It also enables the commander-in-chief to order a general change of position by a single signal, which otherwise would require several. Thus, suppose that the fore, main, and mizen masts, are appropriated, with the proper modifications, for exhibiting the signals addressed to the van, the centre, and the rear squadrons of the fleet, and that a red, a white, and a blue flag, are chosen for the distinguishing flags of the officers commanding these squadrons; then, if the commander-in-chief shall hoist a red flag at his mizen topgallant mast-head, it must direct the van squadron to take the position then occupied by the rear squadron, the evolution necessary for accomplishing this end being supposed known by the commander of the squadron, who will immediately make the necessary signals to the squadron under his particular direction. In the same manner, the distinguishing signal for the leading ship of a squadron being hoisted along with the signal of address to the whole fleet, and the signal for any particular service, will cause the three or the nine leading ships to execute that order.

All that has been said hitherto may be considered as so many preparations for the real issuing of orders by the commander-in-chief. The most difficult part of the language remains, viz. to invent a number of signals which shall correspond to that almost infinite variety of movements and services which must be performed.

Essen qualit signal distin ness.

Distinctness, simplicity, and propriety, are the three essential qualities of all signals. A signal must be some object easily seen, strongly marked, so that it may be readily understood, with little risk of its being mistaken for another. When made by flags, banners, or pendants, they must be of the fullest colours, and strongest contrasts. The ships are frequently at a very great distance, so that the intervening air occasions a great degradation of colour. They are seen between the eye and a very variable sky; and in this situation, especially in the morning or evening, or a dark day, it is not easy to distinguish one full colour from another, all of them approaching to the appearance of a black. At the distance of a very few miles hardly any full colours can be distinguished but a scarlet and a blue. Red, blue, yellow, and white, are the colours which can be distinguished at greater distances than any others, and are therefore the only colours admitted as signals. Even these are sometimes distinguished with difficulty. A yellow is often confounded with a dirty white, and a blue with a red. All other dark colours are found totally unfit. But as these afford but a small variety, we must combine them in one flag, by making it striped, spotted, or chequered, taking care that the opposition of colour may be as great as possible, and that the pieces of which the flags are made up may not be too minute. Red must never be striped nor spotted with blue; and the stripes, spots, or chequers, should never be less than one-third of the breadth of the flag.

Difference of shape, as flags, banners, or pendants, is another distinction by which the expression may be varied. And in doing this, we must recollect, that in light winds it may be difficult to distinguish a flag from a banner, as neither are fully displayed for want of wind to detach the fly from the staff.

Lastly, signals may be varied by their position, which may be on any lofty and well detached part of the masts, yards, or rigging.

Simplicity.

Simplicity is an eminent property in all signals. They are addressed to persons not much accustomed to combinations, and who are probably much occupied by other pressing duties. It were to be wished that every piece of service could be indicated by a single flag. This is peculiarly desirable with respect to the signals used in time of battle. The rapid succession of events on this occasion call for a multitude of orders from the commander-in-chief, and his ship is frequently clad over with flags and pendants, so that it is exceedingly difficult for the signal officer of a private ship to distinguish the different groups, each of which make a particular signal.

Propriety.

These considerations are the foundation of a certain propriety in signals, which directs us to a choice amongst marks which appear altogether arbitrary. Signals which run any risk of being confounded, on account of some resemblance, or because their position hinders us from immediately perceiving their difference, should be appropriated to pieces of service which are hardly possible to be executed, or can hardly be wanted, in the same situation. No bad consequence could easily result though the signal for coming to closer action should resemble that for unmooring, because the present situation of the ships makes the last operation impossible or absurd, Such considerations direct us to select for battle signals, those which are of easiest exhibition, are the most simple, and have the least dependence on the circumstance of position; so that their signification may not be affected by the damages sustained in the masts or rigging of the flag-ship. Such signals as are less easily seen at a distance, should be appropriated to orders which can occur only in the middle of the fleet. Signals which are made to the admiral by private ships may be the same with signals of command from the flag-ship, which will considerably diminish the number of signals perfectly different from each other.

With all these attentions and precautions a system of signals is at last made up, fitted to the code of sailing and fighting instructions. It is accompanied by another small set for the duty of convoys. It must be engrossed in two books; one for the officer of the flag-ship, who is to make the signals, and the other is delivered to every private ship. In the first, the evolutions, movements, and other operations of service, are set down in one column, and their corresponding signals in another. The first column is arranged, either alphabetically, by the distinguishing phrase, or systematically, according to the arrangement of the sailing and fighting instructions. The officer whose duty it is to make the signals turns to this column for the order which he is to communicate, and in the other column he finds the appropriated signal.

In the other book, which is consulted for the interpretation of the signals, they are arranged in the leading column, either by the flags, or by the places of their exhibition. The first is the best method, because the derangement of the flag-ship's masts and rigging in time of action may occasion a change in the place of the signal.

The art of signals much improved.

The *Tactique Navale* of the Chevalier de Morogues contains a very full and elaborate treatise on signals. We recommend this work to every sea-officer, as full of instruction. The art of signals has been greatly simplified since the publication of this work, but we cannot but ascribe much of the improvements to it. We believe that the author is the inventor of that systematic manner of addressing the order or effective signal to the different squadrons and divisions of the fleet, by which the art of signals is made more concise, the execution of orders is rendered more systematic, and the commanders of private ships are accustomed to consider themselves as parts of an army, with a mutual dependence and connection. We are ready enough to acknowledge the superiority of the French in manœuvring, but we affect to consider this as an imputation on their courage. Nothing can be more unjust; and dear bought experience should long ere now have taught us the value of this superiority. What avails that courage which we would willingly arrogate to ourselves, if we cannot come to action with our enemy, or must do it in a situation in which it is almost impossible to succeed, and which needlessly throws away the lives of our gallant crews? Yet this must happen, if our admirals do not make evolutions their careful study, and our captains do not habituate themselves, from the first hoisting a pendant, to consider their own ship as connected with the most remote ship in the line. We cannot think that this view of their situation would in the least lessen the character which they have so justly acquired, of fighting their ship with a courage and firmness unequalled by those of any other nation. And we may add, that it is only by such a rational study of their profession, that the gentleman can be distinguished from the mercenary commander of a privateer.

II. *Night Signals.*

It is evident, that the communication of orders by night must be more difficult and more imperfect than by day. We must, in general, content ourselves with such orders as are necessary for keeping the fleet together, by directing the more general movements and evolutions which any change of circumstances may render necessary. And here the division and subordinate arrangement of the fleet is of indispensable necessity, it being hardly possible to particularise every ship by a signal of address, or to see her situation. The orders are therefore addressed to the commanders of the different divisions, each of whom is distinguished by his poop and top-lights, and is in the midst of, and not very remote from, the ships under his more particular charge. Yet even in this unfavourable situation, it is frequently necessary to order the movements of particular ships. Actions during the night are not uncommon. Pursuits and rallyings are still oftener carried on at this time. The common dangers of the sea are as frequent and more disastrous. The system of signals therefore is very incomplete till this part be accomplished.

Night signals must be made by guns, or by lights, or by both combined.

How gun-signals may be varied.

Gun-signals are susceptible of variety both in number and in disposition. The only distinct variation which can be made in this disposition, is by means of the time elapsed between the discharges. This will easily admit of three varieties, slow, moderate, and quick. Half-minute guns are as slow as can easily be listened to as appertaining to one signal. Quarter-minute guns are much better, and admit of two very distinct subdivisions. When the gunners, therefore, are well trained to this service, especially since the employment of firelocks for cannon, intervals of fifteen or twelve seconds may be taken for slow firing, eight or ten seconds for moderate, and four or five seconds for quick firing. If these could be reduced to one-half, and made with certainty and precision, the expression would be incomparably more distinct. A very small number of firings varied in this way will give a considerable number of signals. Thus five guns, with the variety of only quick and moderate, will give twenty very distinguishable signals. The same principle must be attended to here as in the flag-signals. The most simple must be appropriated to the most important orders, such as occur in the worst weather, or such as are most liable to be mistaken. Quick firing should not make part of a signal to a very distant ship, because the noise of a gun at a great distance is a lengthened sound, and two of them, with a very short interval, are apt to coalesce into one long-continued sound. This mode of varying gun-signals by the time must therefore be employed with great caution, and we must be very certain of the steady performance of the gunners.

Note, that a preparatory signal or advertisement that an effective signal is to be made, is a very necessary circumstance. It is usual, at least in hard weather, to make this by a double discharge, with an interval of half a second, or at most a second.

Gun-signals are seldom made alone, except in ordinary situations and moderate weather; because accident may derange them, and inattention may cause them to escape notice, and, once made, they are over, and their repetition would change their meaning. They are also improper on an enemy's coast, or where an enemy's cruisers or fleets may be expected.

Signals by lights.

Signals by lights are either made with lights simply so called, that is, lanthorns shown in different parts of the ship, or by rockets. Lights may differ by number, and by position, and also by figure. For the flag ship always carrying poop or top-lights, or both, presents an object in the darkest night, so that we can tell whether the additional lights are exhibited about the mainmast, the foremast, the mizenmast, and the like. And if the lights shown from any of these situations are arranged in certain distinguishable situations in respect to each other, the number of signals may be greatly increased. Thus three lights may be in a vertitical line, or in a horizontal line, or in a triangle; and the point of this triangle may be up or down, or forward, or aft, and thus may have many significations.

Lights are also exhibited by false fires or rockets. These can be varied by number, and by such differences of appearance as to make them very distinguishable. Rockets may be with stars, with rain fire, or simple squibs.

These two species of signals may be combined.

By varying and combining these, a very great number of signals may be produced, fully sufficient to direct every general movement or evolution, or any ordinary and important service. The Chevalier de Morogues has given a specimen of such a system of night signals, into which he has even introduced signals of address or direction to every ship of a large fleet; and has also given signals of number, by which depths of soundings, points of the compass, and other things of this kind, may be expressed both easily and distinctly. He has made the signals by rockets perfectly similar in point of number to those by lanthorns, so that the commander can take either; a choice which may have its use, because the signals by rockets may cause the presence of a fleet to be more extensively known than may be convenient.

Genera observa tions c cerning night s nals.

The commander-in-chief will inform the fleet by signal, that guns, or perhaps rockets, are not to be used that night. This signal, at the same time, directs the fleet to close the line or columns, that the light signals may be better observed.

It is indeed a general rule to show as few lights as possible; and the commander frequently puts out his own poop and top-lights, only showing them from time to time, that his ships may keep around him.

The signal lanthorns on board the flag ship, and a lanthorn kept in readiness on board of every private ship, to answer or acknowledge signals from the commander-in-chief, are all kept in bags, to conceal their lights till the moment they are fixed in their places, and the preparatory or advertising signal has been made. The commander-in-chief sometimes orders by signal every ship to show a light for a minute or two, that he may judge of the position of the fleet; and the admiral's signal must always be acknowledged by those to whom it is addressed.

It is of particular importance that the fleet be kept together. Therefore the leading ships of the fleet, on either tack, are enjoined to acknowledge the signals of the commander-in-chief by a signal peculiar to their station. Thus the commander-in-chief learns the position of the extremities of his fleet.

In framing a set of night signals, great attention must be given to their position, that they be not obscured by the sails. The nature of the order to be given will frequently determine this. Thus, an order for the rear ships to make more sail, will naturally direct us to exhibit the signal at the mizen peek; and so of other pieces of service. Lanthorns exposed in groups, such as triangles, lozenges, and the like, are commonly suspended at the corners of large frames of laths, at the distance of a fathom at least from each other. Attempts have been made to show lights of different colours; but the risk of mistake or failure in the composition at the laboratory, makes this rather hazardous. Coloured lanthorns are more certain; but when the glasses are made of a colour sufficiently intense, the vivacity of the light, which at no time is very great, is too much diminished. Besides, the very distance changes the colour exceedingly and unaccountably.

III. *Of Signals in a Fog.*

By o ing c tain ral r signa durin fog a many unne sary.

These can be made only by noises, such as the firing of cannon and muskets, the beating of drums and ringing of bells. Fog signals are the most difficult to contrive of any, and are susceptible of the least variety. The commander-in-chief is principally concerned to keep his fleet together; and unless something very urgent requires it, he will make no change in his course or rate of sailing. But a shift of wind or other causes may make this necessary. The changes which he will order, it will be prudent to regulate by some fixed rule, which is in general convenient. Thus, when a fleet is in the order of sailing upon a wind, and a fog comes on, the fleet will hold on the same course. If the wind should come a little more on the beam, the fleet will still keep close to the wind. Certain general rules of this kind being agreed on, no signals are necessary for keeping the fleet together; and the ships can separate or run foul of each other only by difference in their rate of sailing, or by inaccurate steerage. To prevent this, the commander-in-chief fires a gun from time to time, and the ships of the fleet judge of his situation and distance by the sound. The commanders of divisions fire guns, with some distinction from those of the commander-in-chief. This both informs the commander-in-chief of the position of his squadrons, and enables the private ships of each division to keep in the neighbourhood of their own flag ship. On board of every private ship the drum is beaten, or the bell is chimed every quarter of an hour, according as the ship is on the starboard or larboard tack. By such contrivances, it is never difficult to keep a fleet in very good order when sailing on a wind. The wind is almost always moderate, and the ships keep under a very easy sail. It is much more difficult when going large, and separation can be prevented only by the most unwearied attention. The greatest risk is the falling in with strange ships steering another course. But evolutions and other movements are frequently indispensable. The course must be changed by tacking or wearing, and other services must be performed. None, however, are admitted but the most probable, the most simple, and the most necessary.

The commander-in-chief first informs the fleet by the preparatory fog signal, that he is about to order an evolution, and that he is to direct it by fog signals. This precaution is indispensable to prevent mistakes. Along with this advertising signal he makes the signal of the movement intended. This not only calls the attention of the fleet, but makes the ships prepare for the precise execution of that movement. The commanders of divisions repeat the advertising signal, which informs their ships of their situation, and the private ships beat their drums or chime their bells. Thus the whole ships of the fleet close a little, and become a little better acquainted with their mutual position. It is now understood that a movement is to be made precisely a quarter of an hour after the advertisement. At the expiration of this time, the effective signal for this movement is made by the commander-in-chief, and must be instantly repeated by the commanders of divisions, and then the movement must be made by each ship, according to the sailing and fighting instructions. This must be done with the utmost attention and precision, because it produces a prodigious change in the relative position of the ships; and even although the good sense of the commander-in-chief will select such movements for accomplishing his purpose as produce the smallest alterations, and the least risk of separation or running foul of each other; it is still extremely difficult to avoid these misfortunes. To prevent this as much as possible, each ship which has executed the movement, or which has come on a course thwarting that of the fleet, intimates this by a signal properly adapted, often adding the signal of the tack on which it is now standing, and even its particular signal of recognizance. This is particularly incumbent on the flag ships and the leading ships of each division. After a reasonable interval, the commander-in-chief will make proper signals for bringing the fleet to a knowledge of their reunion in this new position.

This must serve for a general account of the circumstances which must be attended to in framing a code of signals. The arbitrary characters in which the language is written must be left to the sagacity of the gentlemen of the profession. It must be observed, that the stratagems of war make secrecy very necessary. It may be of immense hazard if the enemy should understand our signals. In time of battle it might frequently frustrate our attempts to destroy them, and at all times would enable them to escape, or to throw us into disorder. Every commander of a squadron, therefore, issues private signals, suited to his particular destination; and therefore it is necessary that our code of signals be susceptible of endless variations. This is exceedingly easy, without any increase of their number. The commander needs only intimate that such and such a signal is so and so changed in its meaning during his command.

We cannot leave this article without returning to an observation which we made almost in the beginning, viz. that the system of signals, or, to speak more properly, the manner of framing this system, has received much improvement from the gentlemen of the French navy, and particularly from the most ingenious thought of M. de la Bourdonnais, of making the signals the immediate expressions of numbers only, which numbers may be afterwards used to indicate any order whatever. We shall present our readers with a scheme or two of the manner in which this may be done for all signals, both day, night, and fog. This alone may be considered as a system of signals, and is equally applicable to every kind of information at a distance. Without detracting in the smallest degree from the praise due to M. de la Bourdonnais, we must observe, that this principle of notation is of much older date. Bishop Wilkins, in his *Secret and Swift Messenger*, expressly recommends it, and gives specimens of the manner of execution; so does Dr. Hook in some of his proposals to the Royal Society. Gaspar Schottus also mentions it in his *Technica Curiosa;* and Kircher, amongst others of his *Curious Projects.*

M. de la Bourdonnais's method for doing this

M. de la Bourdonnais's method is as follows:—He chooses pendants for his effective signals, because they are the most easily displayed in the proper order. Several pendants, making part of one signal, may be hoisted by one halyard, being stopped on it at the distance of four or six feet from each other. If it be found proper to throw out another signal at the same time and place, they are separated by a red pendant without a point. His colours are chosen with judgment, being very distinctly recognised, and not liable to be confounded with the addressing signals appropriated to the different ships of the fleet. They are, for

No.	No.
1. Red.	6. Red, with blue tail.
2. White.	7. White, with blue tail.
3. Blue.	8. White, with red tail.
4. Yellow.	9. Blue, with yellow tail.
5. Red, with white tail.	10. Yellow, with blue tail.

Three sets of such pendants will express every number under a thousand, by hoisting one above the other, and reckoning the uppermost hundreds, the next below it tens, and the lowest units. Thus the number 643 will be expressed by a pendant red with blue tail, a yellow pendant below it, and a blue one below the last.

This method has great advantages. The signals may be hoisted in any place where best seen, and therefore the signification is not affected by the derangement of the flag-ship's masts and rigging. And by appropriating the smaller numbers to the battle signals, they are more simple, requiring fewer pendants.

It might be rendere much simpler.

As this method requires a particular set of colours, it has its inconveniences. An admiral is often obliged to shift his flag, even in time of action. He cannot easily take the colours along with him. It is therefore better to make use of such colours as every private ship is provided with. One set of 11 will do, with the addition of three, or at most of four pendants, of singular make, to mark 100, 200, 300, 400. Two of these flags, one above the other, will express any number under 100, by using the 11th as a substitute for any flag that should be repeated. Thus the 11th flag, along with the flag for eight or for six, will express the number 88 or 66. Thus we are able to express every number below 500, and this is sufficient for a very large code of signals.

And in order to diminish as much as possible the number of these compound signals, it will be proper that a number of single flag signals be preserved, and even varied by circumstances of position, for orders which are of very frequent occurrence, and which can hardly occur in situations where any obstructions are occasioned by loss of masts or otherwise. And farther, to avoid all chance of mistake, a particular signal can be added, intimating that the signals now exhibited are numerary signals; or, which is still better, all signals may be considered as numerary signals; and those which we have just now called single flat signals may be set down opposite to, or as expressing the largest numbers of the code.

This method requires the signal of advertisement, the annulling signal, the signal of address to the particular ship or division, the signal of acknowledgment, the signal of indistinctness, of distress, of danger, and one or two more, which in every method must be employed.

Another method of expressing numbers by fewer colours.

Another method of expressing numbers with fewer colours is as follows: Let the flags be A, B, C, D, E, F, and arrange them as follows:

	A	B	C	D	E	F
	1	2	3	4	5	6
A	7	8	9	10	11	12
B	13	14	15	16	17	18
C	19	20	21	22	23	24
D	25	26	27	28	29	30
E	31	32	33	34	35	36
F	37	38	39	40	41	42

The number expressed by any pair of flags is found in the intersection of the horizontal and perpendicular columns. Thus the flag D, hoisted along with and above the flag F, expresses the number 40, &c. In order to express a greater number, (but not exceeding 84), suppose 75, hoist the flag $\genfrac{}{}{0pt}{}{C}{E}$, which expresses 33, or 75 wanting 42, and above them a flag or signal G, which alone expresses 42.

This method may be still farther improved by arranging the flags thus:

	A	B	C	D	E	F
	1	2	3	4	5	6
A	7	8	9	10	11	12
B	—	13	14	15	16	17
C	—	—	18	19	20	21
D	—	—	—	22	23	24
E	—	—	—	—	25	26
F	—	—	—	—	—	27

In this last method the signification of the signal is totally independent of the position of the flags. In whatever parts of the ship the flags D and E are seen, they express the number 23. This would suit battle signals.

A third method.

Another method still may be taken. Flags hoisted anywhere on the foremast may be accounted units, those on the mainmast tens, and those on the mizenmast hundreds. Thus numeral signals may be made by a ship dismasted, or having only poles in their place. Many other ways may be contrived for expressing numbers by colours, and there is great room for exercising the judgment of the contriver. For it must always be remembered, that these signals must be accompanied with a signal by which it is addressed to some particular ship or division of the fleet, and it may be difficult to connect the one with the other, which is perhaps shewn in another place, and along with other executive signals.

Advantages of numeral signals.

One great advantage of these numeral signals is, that they may be changed in their signification at pleasure. Thus, in the first method, it can be settled, that on Sundays the colours A, B, C, D, &c., express the cyphers 1, 2, 3, 4, &c., but that on Mondays they express the cyphers 0, 1, 2, 3, &c., and on Tuesdays the cyphers 9, 0, 1, 2, &c., and so on through all the days of the week. This mean of secrecy is mentioned by Dr. Hooke for the coast and alarm signals, where, by the bye, he shews a method for conveying intelligence over land very similar to what is now practised by the French with their telegraph.

Numbers may be also expressed by night signals.

It is equally easy to express numbers by night signals. Thus M. de la Bourdonnais proposes that one discharge of a great gun shall express 7, and that 1, 2, 3, 4, 5, 6, shall be expressed by lights. Therefore to express 24, we must fire three guns, and shew three lights. This is the most perfect of all forms of night and fog signals. For both the manner of firing guns and of exhibiting lights may be varied to a sufficient extent with very few guns or lights, and with great distinctness.

Thus, for guns. Let F mark the firing of a single gun at moderate intervals, and *ff* a double gun, that is, two discharged at the interval of a second. We may express numbers thus:

1	F.
2	F, F.
3	F, F, F.
4	F, F, F, F.
5	F, *ff*.
6	F, F, *ff*.
7	F, *ff*, F.
8	F, *ff*, FF.
9	F, *ff*, F, *ff*.
10	*ff*.
100, &c.,	*ff*, *ff*, or *fff*.

It might be done with fewer guns if the *ff* were admitted as the first firing. But it seems better to begin always with the single gun, and thus the double gun beginning a signal distinguishes the tens, &c.

In like manner, a small number of lights will admit of a great variety of very distinct positions, which may serve for all signals to ships not very remote from the commander-in-chief. For orders to be understood at a very great distance, it will be proper to appropriate the numbers which are indicated by signals made with rockets. These can be varied in number and kind to a sufficient extent, so as to be very easily distinguished and understood. It is sufficient to have shewn how the whole, or nearly the whole notation of signals, may be limited to the expression of numbers.

Conclu remark

We have taken little notice of the signals made by private ships to the commander-in-chief. This is a very easy business, because there is little risk of confounding them with other signals. Nor have we spoken of signals from the flag ships whose ultimate interpretation is number, as when ships are directed to change their course so many points. Those also are easily contrived in any of the methods already described; also when a private ship wishes to inform the commander-in-chief that soundings are found at so many fathoms. In like manner, by numbering the points of the compass, the admiral can direct to chace to any one of them, or may be informed of strange ships being seen in any quarter, and what is their number. (B. B. B.)

Of late years, that is, within this century, a great improvement has taken place in the signal department of the Royal Navy. The following brief memorandum on the subject will give as general an idea on the subject as could be given without the introduction of coloured plates, and more copious explanations than are consistent with the plan of this work.

There are three volumes of signals in use in the navy; one is called "General Signals," the other "Night and Fog Signals," the other "Vocabulary Signals, for the use of her Majesty's fleet." The *General Signals* consist of a set of numerical references, from 1 to 999, and contain all the most general orders relating to action, sailing, manœuvring, and every other evolution in use, either at sea or at anchor. All these signals are made by means of a set of numeral flags, from 1 to 9, with the addition of zero; a set of divisional flags, to distinguish the different parts of a fleet; flags to affirm signals, to annul them, and to prepare measures; interrogative, answering, compass, geographical, and horary pendants. These, with the union jack, compose the flags in use when the general signal-book is employed. All these flags and pendants depend upon their form and colour for their distinction, and are hoisted at the most conspicuous places for being seen, but seldom more than three at a time. Besides these, distant signals are made with square and triangular flags and pendants, without any regard to their colour. They are numeral, and each has its signification attached to its number in the general signal-book. The distinctive mark of a distant signal is a ball, which is used as a preparative, a stop, or an answer.

In the general signal-book are detailed sets of instructions relative to the line of battle and order of sailing, each signal for a specific evolution being accompanied by a plate, explanatory of the measure contemplated.

The *Night Signals* are made with lanterns, rockets, blue lights, and guns. The numbers are not many, and care is taken to confine the signals to those objects of the most general application in practice, so as not to complicate or confuse; for it may be observed, that night signals are almost always very difficult both to make and to interpret.

The *Vocabulary Signals* are made by means of twenty-one symbols, named A, B, &c., to Y inclusive, (all the alphabet, omitting J, U, W, X, and Z, but retaining I and V). There are no numeral flags used in this code, and no more than three symbols are used at one time. These symbols are made with square and triangular flags, with the occasional use of pendants, to distinguish the alphabetical, the military, and the geographical, parts of the vocabulary from one another. The vocabulary signals, with their significations, are arranged in the following order: words and sentences, alphabet, military phrases and terms, geographical table, and list of the navy. The words and sentences are placed together, the words being arranged in alphabetical order, the sentences immediately following their most prominent words. This book is divided into three parts, but as the number of words required to be used would exceed the power of combination of three symbols, a distinctive pendant is used, to signify which portion of the book is to be referred to, and in this way the same combinations may be used several times over. The military table consists of such technical terms and phrases as are likely to occur on general service. The geographical table contains the names of places, while the body of the volume consists of words and sentences for universal use.

A code of signals for the use of the mercantile marine was published by Captain Marryat, of the Royal Navy, in 1817; it has, we believe, been in general use ever since, and has run through many editions.

The flags and pendants used in Captain Marryat's mercantile code of signals are fifteen, exclusive of the Union Jack, which, by order in Council, when used in the merchant service, is to have a white border all round, such border being one-fifth of the breadth of the Jack itself without the border.

There are ten numerical flags, which represent the figures in arithmetic, and are used throughout the whole of Captain Marryat's code of signals.

The Union Jack, as above distinguished from that used by men of war, which Jack, we may mention, viz. that with the white border, is now used in the navy only as a signal for a pilot.

The *first distinguishing pendant* is hoisted over the number, or at some other mast-head, when the number of a merchant ship is shown in part *second* of the code.

The *rendezvous flag* is hoisted over the number of the port in part *third*.

The sentences in part *fourth* are expressed by the *numerical flags* alone.

The *second distinguishing pendant* is hoisted over the numbers in the first division of the vocabulary.

The *telegraph flag* is hoisted at some other mast-head, when the numbers in the second division of the vocabulary are shown.

The *numerical pendant* is hoisted over a number, when merely the figures are intended to be shown.

The code of signals consists of six parts.

1st, A list of the names of men-of-war.

2d, A list of the names of merchant ships, copied from Lloyd's Register.

3d, A list of ports, headlands, rocks, reefs, shoals, &c.

4th, A selection of sentences.

5th, The first division of the vocabulary consists of compass signals, ships' stores, auxiliary verbs, and final terminations, to assist in spelling words.

6th, The second division of the vocabulary consists of the alphabet, and words most likely to be used in commercial and maritime affairs. The alphabet is introduced for the purpose of spelling words which are not found in the vocabulary.

It is certainly much to be wished, that every means should be used to induce merchant ships to adopt some code of signals; and we trust the gallant and accomplished author, who is so well known in other walks of literature, will not relax his exertions in this humble but very useful department of writing, but that he will study, by fresh editions, to keep his code always up to the wants of the day.

For the rest, we are of opinion that the subject of signals, both in the navy and in the merchant service, is one which requires more attention than it has yet met with. It would seem highly desirable, for instance, that a universal code, sanctioned by their respective governments, should be adopted amongst all the trading nations of the world. If the great maritime countries were to promulgate one grand code, it would speedily be adopted by all, and every ship would then be able to communicate with any other at sea, without the necessity of coming within hail, which is always troublesome, and often impossible. We all now use the same or similar charts; we all use the same methods of navigating our ships, by chronometers, lunars, and so forth; the manipulations of our seamanship are all alike; and why should not our means of communicating by signal be the same? (B. T.)

SIGNATURE, in *Printing*, is a letter put at the bottom of the first page at least, in each sheet, as a direction to the binder in folding, gathering, and collating them. The signatures consist of the capital letters of the alphabet, which change in every sheet; and if there be more sheets than letters in the alphabet, a figure is placed before the signature, as 2 A, 2 B, &c., which are repeated as often as necessary.

SIGNET, one of the king's seals, made use of in sealing his private letters, and all grants that pass by bill signed under his Majesty's hand. It is always in the custody of the Secretaries of State.

SILBERBERG, a town of the Prussian province of Silesia, in the circle of Frankenstein. It is an open town in a mining district in a narrow valley, surrounded with hills, on whose sides the streets are built, but the valley is 1350 feet above the level of the sea. The inhabitants are occupied in making cloth, and in exploring the mines. It is chiefly remarkable from fortified points on five hills, which overlook the town, and which are so connected with each other by works, as to form a most complete citadel, which is surrounded by a ditch seventy feet in depth, and which has within its barracks a natural cavern, sufficiently commodious to lodge securely a garrison of 5000 men. When, in the campaigns of 1806 and 1807, the whole of Prussia was subdued by the French, this place alone defended itself up to the conclusion of the peace of Tilsit.

SILESIA, a large tract of country, now divided between Austria and Prussia. In ancient times, it was inhabited by two rude tribes, called the Lygiern and the Quadi, who were subdued in the sixth century by the Sclavonians, by which it became subject to Poland. Their manners and language, as well as the Christian religion, were introduced by the conquerors. The first bishopric was founded in 966, at Schmogen, from whence it was subsequently removed to the city of Breslau.

In the year 1138, Boleslaus the III., regent of Poland, divided his states amongst his sons, and gave over to his eldest, Wladislaus, Silesia, with some other estates, and the greatest authority in the government. His brothers, however, conspired against him, and succeeded in expelling him from the country. The three brothers divided the land into portions to each, who thus became the founders of the three dukedoms of Silesia, belonging to the race of the Piastis. As the progeny of these dukes multiplied, their respective portions were subdivided, and thus gave rise to the great number of principalities of which the country consists. Besides these, there were other princes, especially in Upper Silesia, who were the descendants of Ottohar, king of Bohemia, who died in 1278, after establishing the dukes of Troppau, Jagendorf, and Raliber. When king John had succeeded to the throne of Bohemia, he was anxious to unite all the power in his own hands, under the pretext of restoring tranquillity to the country, which had been weakened by internal quarrels and hostility He was so far enabled to succeed, in 1327, in persuading the several princes to receive their lands as a feud from him, that two only of the whole number, the prince of Jauer, and the prince of Schweidnitz, declined compliance. In the next reign, when John was succeeded by his son, the emperor Charles IV. of Germany, these two principalities came into his possession by marriage; and Silesia was thus formed into one dukedom, in connexion with the kingdom of Bohemia, in the year 1355. At this time, the king of Poland relinquished all claim over Silesia, and renewed his renunciation by a subsequent treaty in 1372.

Under the Bohemian monarchy, the religious tenets of Huss, Luther, Calvin, and Swenkfeld, spread themselves over the whole country, and the adherents to them were, under some restrictions, permitted to exercise their own forms of worship.

In 1498, a kind of constitution was imparted to the country, which, whilst it gave consistency to it as a whole, lessened the power of the nobility, and increased that of the king, Wladislaus, who then filled the throne. Under him, as well as under his predecessors, since the Polish renunciation, the language and manners of the Poles were gradually exchanged for those of the Germans, and industry, and commerce, and with them, the arts and sciences, were gradually extended. They, however, received a severe check by the persecution of the protestants which was barbarously carried on by the successive princes of the house of Austria. The tremendous scourge of religious and civil war extended from Bohemia to Silesia.

The peace of Westphalia gave tranquillity to the country, for though that treaty was less productive of religious toleration in the dominions of Austria, than in the other divisions of Germany, yet a degree of it was allowed to the protestants, though with imperfect securities for its continuance. Under that house, however, to which it passed, in the early part of the sixteenth century, it was tolerably prosperous; manufactures were introduced, the land was well cultivated, and a degree of ease enjoyed by the inhabitants, to which their ancestors had been utter strangers.

After a century of increasing advancement, Silesia became the theatre of a tremendous war. The death of the emperor Charles VI., when the throne devolved on a female, revived a long dormant and certainly fictitious claim to the western part of Silesia, by Frederick of Prussia, commonly surnamed the great. No justification of his conduct could be made; indeed, in his memoirs his ambition is avowed. He and Bavaria made attacks on Austria on each side, which received some aid both from England and France. The contest was carried on with alternate success, and terminated by the cession of Silesia to Prussia. But the proud house of Austria had no intention of definitively relinquishing such a valuable province. A war commenced in 1756, when France, Saxony, Russia, and Sweden, formed an alliance against Prussia, which brought the king and his country to the brink of ruin, from which it was saved by the talents of the monarch, and some aid from England. After seven years of hostilities, the peace of Hubertsburg was concluded in 1763, by which Silesia was finally settled under the government of Frederick, and has remained subject to his successors to the present time.

Prussian Silesia, according to its present limits, (for a portion of Silesia is still retained by Austria,) extends in north latitude, from 49° 49′ to 52° 1′; and in east longitude, from 14° 20′ to 19° 17′, and comprehends 15,945 square miles. It is bounded on the north-west by Brandenburg, on the north-east by Posen, on the east by Poland, on the south-east by Cracow and Galicia, on the south by Moravia, and on the south-west by Bohemia.

It is divided into the governments, taking their names from the cities where the administrative boards are fixed, viz. Breslau, Oppeln, and Liegnitz. In these, are 186 cities and towns, and 5355 villages and hamlets. It is the most densely peopled of any portion of the Prussian dominions; and it appeared by the census of 1831, that the number of inhabitants was 2,464,413; the births exceeding the deaths at the rate of 100,000 annually. Nearly one half the inhabitants are Catholics, the others are chiefly Lutherans, with about four or five thousand Calvinists, some Menonites, Hussites, and Hernhutters, and about 17,000 Jews. Each of these sects have their establishments for education, and a University in Breslau, open to all, without distinction of religious opinions.

The river Oder runs from south to north, and divides the province into two parts of different character, as to the face of the country. On the east, it presents a flat sandy plain of rather a sterile appearance. On the eastern or German side, the land is rather mountainous, presenting much variety of scenery, with a good soil, though intermixed with extensive tracts of sandy land.

In the part of the province where it touches on Bohemia is a mountainous range, some of whose peaks are very lofty. The Reisenkoppe is 4950 feet, the Grasse-Rad 4070, and several others above 4000.

The state of agriculture is much improved, and the land produces a sufficiency, in some years a surplus, of corn, consisting chiefly of rye, with about one-fifth as much wheat. The cultivation of flax is, however, the employment to which the greatest skill is directed, and in some years 17,000,000 pounds have been raised, the greater part of which was used in the manufactures of the province. Tobacco, fruit, and culinary vegetables are abundant, and in the southern part, some moderate wine is made. The mines are considerable, and yield still a little gold and silver, and abundance of copper, lead, iron, calamine, arsenic, vitriol, sulphur, zinc, and cobalt. This country has been long celebrated for its manufactures of fine linen; their shirtings are exquisite, both for strength and fineness, and no other table linen has yet been made that can rival theirs. Of late years the cotton trade has been introduced, and is increasing. The chief commerce is in manufactures, and the exportation of pitch, tar, and turpentine. The imports of foreign goods reach them by the way of the Oder from Stettin, or by the Elbe from Hamburg.

Breslau, the capital, contains 90,000 inhabitants.

The portion of Silesia left to Austria by the peace of Hubertsburg, has been incorporated with Moravia, and makes a part of the government of Bran. It is formed into the following circles, viz. Teschen, Bielitz, Freudenthal, Freistadt, Friedeck, Deutchleuthen, Reschenwaldau, and Roy, each named from the chief city of the district.

It is bounded by Prussian Silesia, by Galicia, by Moravia, and Hungary. It comprises 27 cities, 4 towns, and 646 villages, with about 380,000 inhabitants. The country is mountainous; the Carpathian range is partly on the eastern side of it, and the Moravian on the west. Much of the land is very productive in corn, pasture, and wood. The people are mostly of Sclavonian origin, and speak the Polish language more than the German. In the city of Bielitz are manufacturers of woollen goods, and in all parts linen is made from flax grown near them, which is both good and abundant. There are good grammar schools in Teschen, Troppau, and Weisswassen.

SILICERNIUM, amongst the Romans, was a feast of a private nature, provided for the dead some time after the funeral. It consisted of beans, lettuces, bread, eggs, and other things. These were laid upon the tomb, as a repast for the dead.

SILIUS ITALICUS, CAIUS, a celebrated Roman poet, and author of an epic poem in seventeen books, which contains a history of the second Punic war, was born in the reign of Tiberius, and is supposed to have derived the name of *Italicus* from the place of his birth; but whether he was born at Italica in Spain, or at Corfinium in Italy, which, according to Strabo, had the name of *Italica* given it during the Social war, is a point which is unascertained. When he came to Rome, he applied himself to the bar; and, by a close imitation of Cicero, succeeded so well, that he became a celebrated advocate, and a most accomplished orator. His merit and character recommended him to the highest offices in the republic, even to the consulship, of which he was possessed when Nero died. He is said to have lent his assistance in accusing persons of high rank and fortune, whom that wicked emperor had devoted to destruction; but he retrieved his character afterwards by a long and uniform course of virtuous behaviour. Vespasian sent him as proconsul into Asia, where he behaved with clean hands and unblemished reputation. After having thus spent the best part of his life in the service of his country, he resolved to consecrate the remainder to retirement and the muses. He had several fine villas in the country; one at Tusculum celebrated for having been Cicero's, and a farm near Naples, said to have been Virgil's, at which was his tomb, which Silius often visited.

He has imitated Virgil, and though he falls infinitely short of him, yet he has discovered a great and universal genius; which would have enabled him to succeed in some degree in whatever he undertook. Having been for some time afflicted with an imposthume, which was deemed incurable, he grew weary of life, to which, in the language of Pliny, he put an end with determined courage. There have been many editions of Silius Italicus. A neat and correct one was published at Leipsic in 1696, in 8vo, with short and useful notes by Cellarius; but the best are those *cum notis integris Variorum et Arnoldi Drakenborch*. Traject. ad Rhenum, 1717, in 4to.; and *cum notis Ruperti*, 2 vols. 8vo. Gott. 1795.

SILK. Under the head SILK-WORM, will be found an account of the first introduction of the insect, and the commencement of the manufacture in the western empire. From thence it spread into Sicily and Italy; and during the time that the French occupied Milan (1521), artizans were conveyed by Francis I. to Lyons, and under his protection, the manufacture of silk made great progress.

When the Duke of Parma took and plundered the city of Antwerp in 1585, a great proportion of the merchants and artizans took refuge in England; these introduced the silk manufacture into this country, which was fostered and encouraged by the English government. Before this period the produce of the silk-worm had been little seen in England.

The climate of England has not been found favourable for the rearing of silk-worms; repeated attempts have been made from time to time to cultivate the breed, but they have always failed. It was supposed that the British settlements in America would prove more favourable for this purpose, and in several of them the experiment was made, but from some cause or other, these were not more successful than those of the mother country.

The manufacture of silk goods has been the object of solicitous care to the British government, and various enactments were made by successive monarchs, with the view of encouraging it in this country. It received a great stimulus in 1685, when the revocation of the edict of Nantes banished from France multitudes of her most industrious and skilful artificers, which greatly benefited the countries that sheltered the injured emigrants. About 70,000 took refuge in England and Ireland, and transplanted various branches of the useful arts to different districts of this country. A large body of silk weavers settled in Spittalfields, where descendants of many of them may still be found.

England was, however, entirely dependent on foreigners for organzine silk thread, till Mr. Lombe of Derby, in the year 1718, having gone to Italy in the disguise of a common workman, took drawings of the silk-throwing machinery in Piedmont, and, on his return, erected a large mill on the river Derwent at Derby. The extensive and powerful machinery of this mill contained 26,586 wheels, and 97,746 movements, which worked 73,726 yards of organzine silk thread, by every revolution of the water-wheel, which revolved three times in the minute, and thus produced 318,504,960 yards of organzine per day.

The silk manufacture continued to increase in England, though the workmen were constantly clamouring against the importation of foreign goods. With a view to encourage the manufacture, an act was passed (3 Geo. I. cap. 15) for granting bounties on the exportation of silk fabrics; this was, however, no more than a drawback of part of the duties paid on the importation of the raw silk. In 1741, permission was given to the Russia Company to import the raw silk of Persia at the same rate of duty as from the Levant; and, in 1749, the same reduction was made on the duties on raw silk imported by the East India Company from China. In 1764, the fashion of the times running in favour of French silks, and the wages of the English weavers being low, and work scarce, the operatives assembled in great multitudes, and in a tumultuous manner presented petitions to Parliament praying for the total prohibition of foreign wrought silks. By the representation which the operatives made of their sufferings, Parliament was induced to reduce the duties on raw and thrown silk, and entirely to prohibit the importation of certain articles of manufactured silk goods. The operative weavers did not, however, derive those benefits from the prohibitions against importation, which they expected, and they had frequently recourse to combinations to force their masters to raise their wages. These disputes between the masters and workmen having led to violence and riot, an act was passed in 1773, and confirmed by two subsequent acts, empowering the aldermen of London, and the magistrates of Middlesex to fix the wages of the Spittalfields weavers. But it is unnecessary to recapitulate the applications of the operatives and manufacturers for protection against foreign competition, and the attempts of the legislature to encourage the manufacture by restrictive and prohibitory enactments from 1773 to 1824; the silk trade in England, from the futile attempts to bolster it up, was kept in an artificial and languishing state. The manufacturer, depending upon the protection of Parliamentary restrictions on foreign competion, rather than on his own skill and exertions, was not anxious to discover and introduce improvements into the manufacture. Since the change of system, the imports of the raw material, and the exports of the manufactured article have rapidly increased; at present the value of the manufacture is supposed to exceed L.10,000,000 annually, and considerable quantities of manufactured silk are exported to France itself.

The following Table shows the Quantities of Raw and Manufactured Silk, Imported, Exported, and retained for Consumption, during the years 1836 *and* 1837, *with the Rates of Duty.*

DESCRIPTION.	Quantities Imported.		Quantities Exported.		Quantities retained for consumption.		Rates of Duty.

Nothing more fully demonstrates the folly of attempting to encourage manufactures by prohibiting importation than the history of the silk trade. The greatest importation of raw and thrown silk which took place in any one year, previously to the repeal of the prohibitory system, was in 1833, when the quantity imported was 2,432,286 lbs.; while, by the foregoing table, it appears that 5,320,965 lbs. were imported in 1837, at the same time that the official value of our silk manufactures exported during the same period, was L.140,520 during 1823, and L.503,673 during 1837; of which, the proportion exported to France was L.43,144.

Those who are best qualified to form an opinion, consider the duty of 30 per cent. on the importation of silk goods still too high, and that the duty should be reduced to 15 or 10 per cent.

In no country has the silk manufacture made more rapid advances of late years than in Prussia. In 1831, the number of looms was 8,956; in 1834, they had increased to 12,044; and in 1837, to 14,111.

The following table shows the excess of exports from Prussia over the amount of the imports:—

	Silk Goods.			Mixed Silk Goods.		
	Imports.	Exports.	Excess of Exports.	Imports.	Exports.	Excess of Exports.
	lbs.	lbs.	lbs.	lbs.	lbs.	lbs.
1834	254,985	559,079	304,094	106,950	320,266	213,316
1835	201,981	762,004	560,023	106,596	371,971	265,375
1836	225,581	847,826	622.245	121,236	404,435	283,199

The duty on the importation of silk goods into Prussia, is 110 dollars per centner, or 2s. 9d. per lb., which is almost five per cent. on the value of the goods. The import duty on mixed silk goods is 55 dollars per centner, which is equal to 1s. 4½d. per lb., or almost nine per cent. *ad valorem.*

Silk *Manufacture.* The processes of silk manufacture fall under two great divisions. The one, comprehending all those operations undergone by the silk in its preparation for textile or other purposes; and the other, those by which the prepared silk is formed into the various beautiful creations of the loom. The operations comprehended in the first division being for the most part peculiar to this manufacture, are those which will here occupy our attention; while those of the second division, being common to the various textile substances, will be found described under the general head Weaving.

In other textile substances, the manufacturer operates upon bundles of short fibres, which, by drawing out and twisting together, he forms into continuous threads; but in the case of silk, a very different treatment is for the most part required. Here the silk-worm is the spinner, and art is called in, not to join short filaments, but so to strengthen the delicate threads of the worm by combination, as to fit them to endure the manipulations to which they are afterwards subjected. We have said for the most part, for this reason, that, from the manner in which the worm labours, there arises a necessity for two modes of operating, one of the nature already described, the other analogous to that of the cotton-spinner; and that the reader may be prepared to understand the reason for this, and many other peculiarities arising from the same cause, we shall here present him with a sketch of the manner in which the worm produces the material to be operated upon; and this sketch needs to be but brief, as in the article Silk-Worm, immediately sequent, the fullest information will be found. When the silk-worm has arrived at that stage of its existence at which it begins to spin, it ceases to feed, grows restless, and moves about, seeking a place wherein to commence its labours. When it has found a corner or hollow fit for its purpose, it attaches long threads from side to side, to form supports for its work; these it does not dispose in any regular manner, but crosses and recrosses them in such a way, as to make its work as strong as the situation will admit of. In plying its labours, the little creature by degrees narrows their sphere, and when it has enclosed a space of about the size of a pigeon's egg, its work assumes a more regular character, and shortly presents the appearance of a loose silken ball of an oval shape, with the worm labouring inside of it. In a little while, the increasing compactness of the ball renders the labours of the worm no longer evident to the eye, and that it continues to work can only be known by the noise within. When all sound has ceased, the formation of silk has also ceased. Although from the compactness of the ball, the worm labours unseen, we can yet tell by after dissection, and by the unwinding of the thread, that it does not lay its thread regularly round the inside of the ball, but to and fro from one spot to another, for many times, gradually shifting its position, until it has gone over the whole surface, and so gradually, that a great many yards of thread may be unwound without once turning the ball. The substance of which the thread of the silk-worm is composed, is secreted by the animal in the form of a fine yellow transparent gum, and exuded by two minute orifices beneath its jaw; hence the thread is a twin one, formed of two threads proceeding from these orifices, cemented together by a gummy substance, similar to that of which they are formed; and when the worm has finished its labour of spinning, it smears over the whole interior surface of its work with the same gum, doubtless for the purpose of protecting it in its chrysalis state from rain. If we examine the finished work of the worm, we shall find it to consist first of those filaments used as supports, and next of a ball of a loose texture and irregular construction, serving as an envelope for another ball, compact in its nature, and regular in its formation, within which the worm lies enshrouded. This compact ball is called a *cocoon*, and its soft envelope *floss silk.* The thread of the cocoon, from the regularity of its deposition, can be unwound to the end, and the operations to which it is subjected are those of doubling, twisting, twining, and their accessories, classed under the name of silk throwing. The floss silk, with the additions afterwards to be noticed, is not unwound, but, under the name of waste, has its filaments hackled, combed, and reduced to short lengths, and then carded and spun in a manner analogous to those of cotton.

When the spinning of the cocoons is accomplished, a selection of those that are to be kept for breeding is made, and the remainder are assorted according to their qualities. These are generally reckoned nine, and are as follows:

1st, Good cocoons; these are strong, firm, and nearly equally round at both ends, not very large, but free from spots.

2d, Calcined cocoons, in which the worm has died, and been reduced to powder by a disease which sometimes attacks them after having completed their work.

3d, Cocalons, larger and less compact than the good cocoons.

4th, Choquettes, cocoons in which the worm had died before it had finished spinning; the silk is fine, but apt to furze in winding.

5th, Dupion, or double cocoons, containing two or more larvæ; these are difficult to unwind, and are often kept for seed.

6th, Soufflon, cocoons of so loose and soft a texture, as to be almost transparent; these cannot be unwound.

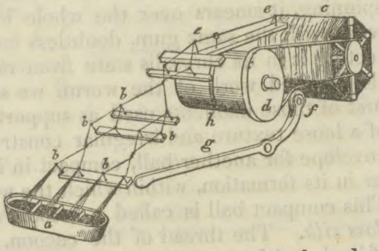
7th, Pointed cocoons. In these one end rises in a point, which breaks off after a little silk has been unwound, and so spoils the thread.

8th, Perforated cocoons, from which the moth has made its way out.

9th, Bad choquettes, in which the silk is spotted, rotten, and blackish in colour.

The first operation to be performed, preparatory to the unwinding of the silk from the cocoon, is to destroy the vitality of the contained worm. The means used for this is heat, either natural or artificial; sometimes simple exposure to the solar rays will effect this object; but in climates where these have not power, some artificial heat must be employed, such as the heat of steam or of an oven, but more generally that of the latter. In this case, the heat should not be greater than what is usual in the oven after the bread has been withdrawn. Long shallow baskets are taken and filled nearly to their tops with cocoons, and are covered over, first with paper, and then with a cloth. In these baskets, the cocoons are exposed to the heat of the oven for nearly an hour, and on being withdrawn, several cocoons are chosen from the part of the basket least exposed to the heat, and the chrysalides in them stripped and pricked with a needle. If upon being pricked, they give no sign of animation, it may be fairly presumed that the destruction of the creatures has been accomplished. Before the silk of the cocoons can be reeled off, it is necessary to separate them from the floss in which they are enveloped; this is effected by opening the floss covering at one end, and protruding the cocoon. It is of the greatest importance in the reeling process, that all the cocoons reeled together be of one class.

Fig. 1.



The apparatus for reeling is sketched in fig. 1, and to avoid confusion, the working parts only are shewn: *a a* is a bath or vessel of water, which, when of the best construction, is heated by steam. Into this the cocoons are put, that the gum which retains the thread in its place may be so much softened as to permit the thread to be unwound; the bath is usually divided by three partitions into four divisions, each of which may contain about five cocoons; *b b b* are wires with eyelets at their ends, through which the filaments from the cocoons are put. In their upward progress towards the reel, the groups of filaments are made to cross and recross each other, before their final combination at the last eyelet, and by the friction thus produced, they are freed from adhering impurities; *c* is the reel driven by a belt from the pulley *d*, which is itself driven by the prime mover, whatever that may be; *f* is a tumbler, whose end carries a pulley, which presses on the belt that drives the reel; by lifting up the long end of the tumbler, the belt is slackened, and the reel stops. The filaments, when combined at the upper eyelet, pass along the guide *e e*, and through eyelets at its ends; this guide has a pin projecting from its under side, working in a spiral groove cut round the barrel *h*; by this it receives a reciprocating motion, and so spreads the filaments equally over the reel.

The filaments, in their passage from the bath to the reel, must necessarily traverse a considerable space, to allow their softened gum to be again hardened by the air, that they may not afterwards adhere together.

In the place where the reeling of silk is performed, many of these machines are arranged along the building, and driven by the moving power through a shaft extending the whole length, carrying on it pullies at the proper intervals. In working the apparatus, the reeler, who is generally a woman, sits at the bath, and having taken a number of cocoons, immerses them in the water. When their gum is sufficiently softened to permit the thread to come off, the reeler takes a whisk formed of fine twigs bound together, and cut off evenly at the ends at about six inches long, and with it she gently presses and stirs the cocoons, and entangles their loose threads on its points; she then raises her whisk with the threads attached to it, disengages them from it, and draws their ends through her fingers, to remove any adhering floss or impurity; this cleaning process is called *battue*. Having thus freed the ends of such a number of the filaments as she means to use, she passes them through the various eyelets in the manner previously mentioned, and attaches them to the reel; when this is accomplished, the reel is put in motion by dropping the end of the tumbler, and the filaments are drawn from the cocoons. It is the province of the reeler so to regulate the motion of the reel, and the heat of the water, that the silk may come off the cocoons regularly, not in lumps, which shows that the water is too hot; nor in such a manner as that the cocoon shall be tossed out of the bath, which shows that the silk is yielded with difficulty, from the water being too cold sufficiently to soften the gum.

From the threads of the cocoons being finer near their termination than at their commencement, it becomes necessary for the reeler to add other cocoons before the first set is quite exhausted; and it is her care to do so in such a manner, as that the requisite thickness of the compound thread may be kept up throughout. It is generally considered that the filaments of three fresh cocoons added to two half-wound ones, make a thread equal to that from four fresh cocoons.

The cocoons are not entirely wound off, but the husk, or *bairré*, in which the worm lies, is left, and used along with the floss silk, under the name of waste.

Every eleven or twelve pounds of cocoons generally yield one pound of reeled silk; and as it takes from 240 to 250 cocoons to weigh one pound, the number of cocoons necessary to produce one pound of silk, may be reckoned to be 2817½; some cocoons may yield about 625 yards of silk, but the average is stated to be 300 yards, consequently the pound of silk filament, as produced by the worm, would, if stretched out, reach the amazing length of 480 miles.

When a sufficient quantity of silk is reeled off, it is doubled into a hank for use or sale; and it is in this state that it generally comes to be operated upon by our manufacturers,—the hanks by the silk throwster, the waste by the silk spinner.

It is of the utmost importance in the succeeding manufacture, that this reeling process should be well performed. Sometimes from the temperature of the water used to soften the gum being too high during the reeling, the parts of the hank of silk that lie on the spokes of the reel become very hard, and occasion the breaking of the thread in the after processes. Sometimes, too, when in the reeling process the threads happen to break, the ends are again only laid upon one another, and not connected by tying; the threads consequently come off the hanks in short lengths, and much trouble and loss of time is experienced in searching for the other end; and sometimes the reelers, either from inattention or design, reel off the whole of the thread of the cocoons, by which an exceedingly foul silk is produced. Not unfrequently, also, coarse and fine silks are reeled together in the same hank; and, what is of common occurrence, the hanks when reeled are twisted up so tight, that the untwisting of them greatly damages the silk. But the greatest injury to the manufacturer arises from dishonesty on the part of those who produce the reeled silk; and this remark applies especially to the coarser descriptions of the *Brutia* silk. To get rid of their waste the producers of this silk roll up the refuse of the cocoon into what are here technically called *dollies*, and insert these into the hanks in such a manner, that they cannot be discerned by the purchaser; they also have a method of mixing their waste with the good silk while it is being reeled, and as it cannot again be separated from it without great injury, this mode of vitiating the silk is more

Manu- ure.

objectionable than the other. But dishonest practices are unfortunately not confined to the description of silk above mentioned; it is too common in all hanks to find some coarse inferior quality of silk artfully prepared with a covering of a much finer kind, to enhance its value.

The loss of capital, which careless reeling, and the base practices we have alluded to, entail on the manufacturer, is immense; for if an establishment be formed, with machinery and workers sufficient to throw a given quantity of good silk; take, for example, the Italian silk, called *Fossombrone*, which, of all the raw silks, is the easiest manufactured, and if, in place of some of the *Fossombrone*, the machines and workers come to be employed on some silks vitiated as we have described, or reeled in a careless manner, then, from the foulness and unevenness of the thread, the number of workers will, in all probability, not be sufficient to attend to above one-third of the machines, one winder being able in a given time to wind five times as much of the *Fossombrone* as of some of the *Bengalese* silks.

From what we have said it may be inferred, that it is a matter of great difficulty for the manufacturer to determine the number of machines and workers in the various processes; and that, from the ever varying nature of the silk, he will seldom have the whole of his machinery employed.

If the preparation of the raw silk, as reeled silk is termed, were conducted by persons conversant with the processes of the silk filature, who would adapt their mode of working to suit the various purposes to which the article prepared by them was to be applied; or, if the whole of the operations were under the conduct of an instructed agent of the manufacturers, the evils on which we have animadverted would be removed, and a better and a cheaper article would be furnished to the consumer.

The operations which succeed the reeling are those of silk throwing, and are as follows:

1st, *Winding* the silk from the hanks upon bobbins, to fit it for the further processes.

2d, *Cleaning*, consisting in the silk being unwound from the bobbins of the winding machine, and wound upon another set of bobbins; and, in its passage between, made to pass through an opening between two metal plates, by which any inequality, caused by knots or adhering substances, is removed.

3d, *Spinning*, consisting in twisting the cleaned thread.

4th, *Doubling*, consisting in laying together on one bobbin the threads of several bobbins, so that they may be afterwards combined by being twisted together.

5th, *Throwing*, the name by which the operation of twisting the doubled silk is known, and also the name by which the whole class of operations is distinguished.

It has been conjectured, that the name *throwing* is derived from the swinging and tossing of the threads and cocoons while reeling, but we need not travel out of the way for its derivation, as the operation of twisting is in many other arts called throwing. The ropemaker *throws* twist into his ropes; and the little instrument used in the farmyard for twisting straw ropes, is called a *throw-crook.*

6th, *Reeling*, consisting in forming into hanks suited for undergoing the processes of scouring, dyeing, and bleaching the silk which has undergone some or all of the previous operations.

7th, After the scouring, bleaching, or dyeing processes have been performed on the hanks, these have again to be wound on bobbins, for the use of the warper or weaver.

It is not to be understood, that silk in every case undergoes all the operations we have mentioned, but that, when it does so, these succeed each other in the order described.

It is sometimes merely wound and cleaned, and is in this state under the name of dumb *singles*, used for Bandana handkerchiefs, and, when bleached, for gauze, and similar fabrics.

Silk Manufacture.

It may be wound, cleaned, and thrown, and is then called *thrown singles,* and used for ribbons and common silks.

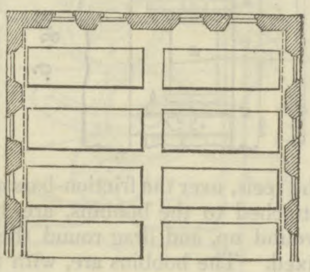
If wound, cleaned, doubled, and thrown, which twists it into one direction, it is called *tram*, and is used for the woof or shute of Gros de Naples, velvets, and flowered silks.

If wound, cleaned, spun, doubled, and then thrown, so as to be of the nature of twine, or the strand of a rope, it is called *organzine*, which, from its strength, is used for warp.

Silk, in any of these states, before being subjected to the operation of scouring, is termed *hard*, but after it is by scouring deprived of its stiffening-gum, it is called *soft.*

The operations of the throwster are generally carried on in a building which admits of an apartment being allotted to each description of machines, and these apartments are generally in stories. All the machines used in the processes are each made up of a repetition of the same parts, each part being a distinct and separate apparatus, capable of performing its work independent of its fellows; and these are arranged in juxtaposition in the *machine*, in order that the moving power may be conveniently applied to a long series of them. The length of the machines is regulated by the extent of the building, and the manner of their arrangement. A manner of arranging them is here sketched (fig. 2.) The apartment is supposed to be about thirty-eight feet wide, and the machines are placed athwart the room, so as to afford a passage four feet in width along the centre, and at such a distance lengthways, as to give room for the workers to attend to their charge. Two shafts traverse each apartment in the direction of the dotted lines, and carry on them pullies, or toothed wheels, opposite to each machine; a belt from each pulley is carried over a corresponding pulley on the end of the main shaft of each machine, or the toothed wheels are connected by proper gearing with the shafts of the machines, and so motion is given to the whole.

Fig. 2.

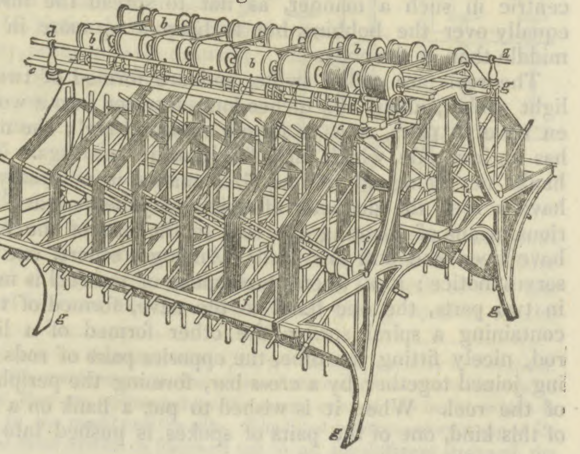


The rooms are generally heated by steam, and the temperature of the apartments, when above the minimum of 50°, is regulated more by a regard to the health of the workers, than from any necessity for a particular temperature in the operations; but these cannot be performed with advantage when the temperature is allowed to fall below 50°.

Winding.

The first machine or apparatus used is the winding-machine, or that by which the reeled hanks are wound on bobbins, to prepare them for the subsequent processes. A perspective sketch of this machine is shewn in fig. 3. Along

Fig. 3.



each side of the machine, at *a a*, directly under the line of bobbins *b b*, run two shafts, called frame shafts, or frame friction-shafts; on these shafts at each bobbin are fixed two friction pullies, of about 4½ inches diameter; and on the axis of each bobbin are fixed two corresponding pullies, about 1⅛ inch diameter. The friction-pullies of the bobbins rest upon those of the shaft, and receive motion from them. Opposite to each bobbin is a wire, with an eyelet at its end, fixed to a bar of wood *c c*, called the traverse bar. This bar, with the eyelets attached, has an alternating motion, right and left, through a space equal to the length of that part of a bobbin on which the silk is to be wound. In front of these eyelets are fixed the guide-rods, or friction rods, *d d d d*, over which the threads glide in their passage from the reel to the bobbins, and which are formed of polished iron, and in front of these the reels *e e e e*, are placed on their bearers *f f*. At every seventh bobbin or so is placed a main frame, like *g g*, and between these stretch bars of wood, for the support of the bobbin and reel bearers. Motion is given to the bobbins, we have said, by the lying shafts bearing friction-pullies, and the threads being passed from the reels, over the friction-bars *d d*, through the eyelets, and attached to the bobbins, are, by the motion of the latter, wound up, and drag round the reel on which the hank is fixed. The bobbins are, with their friction-pullies, represented in figs. 4, 5, and 6. Fig. 4, a section; fig. 5, a front view, and fig. 6, a plan: *a* is the lying-shaft, with one of its friction-pullies *b b*, and on this rests the friction-pulley *c*, of one of the bobbins *d;* the axis of the bobbin is confined laterally by working in the groove *e* of the bearer, but has perfect freedom of motion up and down, so that its friction-pulley may remain in contact with that of the shaft. If, during the process, a thread happens to break, the bobbin is lifted out of its working-groove and placed in the higher groove *f*, by which its friction-pulley is kept from touching the friction-pulley of the shaft, and it consequently remains at rest; but when, after the damage has been repaired, it is lifted into its former position, its motion is immediately resumed. In front of the bobbin is seen the traverse bar *g*, carrying the wire *h*, with its eyelet for the thread; this traverse bar is moved by an eccentric in such a manner, as not to spread the thread equally over the bobbins, but to heap it up more in the middle than at the ends.

Fig. 4.

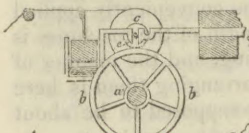


Fig. 5.

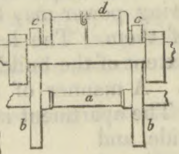

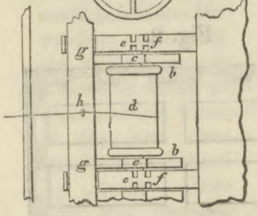

Fig. 6.

The reels are called swifts, and are formed of twelve light spokes, about 16½ inches long, inserted into a wooden nave in pairs, so as to form a six-sided reel; the nave has an iron axle, which turns freely on its bearings. The hanks not being all of one size, makes it necessary to have a reel, the diameter of which may be varied. Various means of adapting the reel to the size of the hank have been and still are used. Amongst others, one deserves notice; it is, where each spoke of the reel is made in two parts, the one fixed to the nave, formed of tube containing a spiral spring, the other formed of a light rod, nicely fitting the tube, the opposite pairs of rods being joined together by a cross bar, forming the periphery of the reel. When it is wished to put a hank on a reel of this kind, one of the pairs of spokes is pushed into the tubes, and the hank slipped on; the spiral springs now exert their force, and throw out the pressed-in spokes with such a force, as to keep the reel in a proper state of tension. But the method generally adopted, if not so elegant, is more simple. The spokes in this case are formed of lance-wood, and the outer extremity of each pair are rather farther asunder than the ends which are inserted into the nave, and are connected together by a band of small cord passed several times round them; on these bands the hank or skein of silk rests, and, by slipping the bands along the spokes nearer to or further from the centre, the diameter of the reel can be adapted to the size of the hank; and when the hank is stretched the bands can be moved in any way, so as to balance the hank, which, as will be afterwards seen, is a matter of considerable importance. Each pair of spokes, it has been mentioned, slightly diverge as they proceed from the nave; and, as they are again slightly drawn towards each other by the bands, the tendency to return to their natural position effectually retains the band in any place to which it may be slipped. It has been said, that the reels turn freely on their supports, but it is necessary to create such a friction as will prevent them giving off the silk faster than it can be taken up by the bobbins; this is sometimes done by a spring being made to press upon the nave of the reel, but more commonly by hanging on its centre a wooden ring, to which weights may be hung, so as to create such a degree of friction on the reel, and, consequently, of tension upon the thread, between the reel and the bobbin, as may be desired. The subjoined sketch (figs. 7 and 8.) shews the reel as it has been described: *a* is the nave, *b b* the lance-wood spokes, *c c* the bands of cords forming the periphery of the reel, *d* the friction-ring, with the weight hanging on it.

Fig. 7.

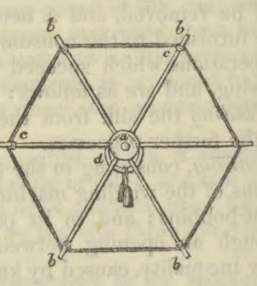

Fig. 8.

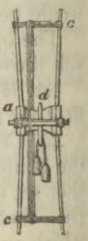

Referring again to fig. 3, it will be seen, that in front of the swifts are bars of wood, extending along both sides of the machine; their use is to support the bars which carry the swifts, and to prevent the persons of those who work the machines from coming in contact with the reels; from this last use they are termed knee-rails.

Previous to the hanks being put upon the swifts, they are washed in a solution of soap and water, which cleans the silk without depriving it of its gum. In putting the hanks on the reel care is taken to balance them, as, were one side heavier than another, it would be apt to fall suddenly, after having passed the highest point, in turning, and thereby injure the thread.

The winding-machines, under the general superintendence of a man called a steward, are tended by girls, who are termed *denters* and *winders;*' the denters put the hanks on the reel, and the winders, or piecers as they are also called, tie the ends of the threads and exchange the bobbins. When the bobbins are filled with thread they are conveyed from the winding-machine room to the warehouse, to be assorted or separated into finer or coarser qualities, which are kept apart throughout the remaining processes. To carry the bobbins, a board, called a *doffing-board*, is made use of; this consists of a piece of deal, about a foot wide, and rather more than two feet long, having a number of wires corresponding to the number of bobbins in one side of a frame, and about four inches long, inserted into its surface; on these wires the bobbins are put. When the separation of the qualities has been made, the bobbins are carried to another machine-room, where the thread undergoes the operation of cleaning.[1]

Cl ing.

The *cleaning*, *drawing*, or *picking-machine*, as it is variously called, is represented in fig. 9. In this, as in the last machine, motion is communicated to the bobbins by a friction shaft. The bobbins, *a a*, from the winding-frame are fixed on plain spindles, and placed in a horizontal position between their supports. The threads are carried from the bobbins over the iron or glass rod, *b b*, and each thread is passed through an adjustable opening, between the two iron blades of an instrument called the *cleaner*, *c c*, which is fixed to a bar of wood running along the machine, immediately behind the friction-rods. The *cleaner* is here represented on a larger scale, (figs. 10, 11); *a* is the bar of wood to which the instrument is fastened; *b*, *b*, are the blades, which are held together at the bottom by the screw *c*; *d* is the opening through which the thread is made to pass, the width of this opening being adjusted by means of a screw *e*, the key of which is kept by the steward of the room. The tops of the blades are curved outwards, so as readily to guide the thread into the slit. The threads, after having been passed through the opening of the cleaner, are put through the eyelet *d*, of the traverse bar, which is, in every respect, like that of the former machine, and then attached to the bobbins *e e*. When the machine is put in motion, the bobbins *e e* drag the thread from the bobbins through the cleaner; and, as the cleaner is adjusted to a certain size, all impurities and irregularities are removed, and the thread thus rendered equal.

Fig. 9.

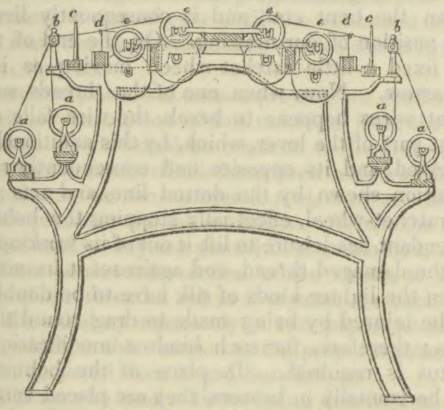

Fig. 10.

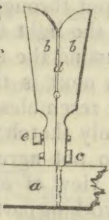

Fig. 11.

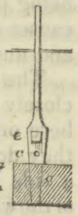

Spin g.

The process which succeeds that of cleaning is called spinning, although, as we have already observed, it is only twisting. The spinning-machine is represented in fig. 12. This, like the two former machines, consists of a series of frames placed at wide intervals, and connected by bars of wood, which serve as supports for the different parts of the machinery. The spinning machine contains sometimes two but generally three tiers of working apparatus in height. The bobbins on which the twisted silk is to be wound, are seen in the figure at *a a a*, placed horizontally along the machine; in this case they are not driven by friction-rollers, but by toothed wheels, fixed on the extremity of the axis of each bobbin, and corresponding ones on the shafts *b*, *b*, *b*. The bobbins are, as before, suspended by their axis in little grooves; each bobbin-bearer contains two such grooves, one higher than the other, so that, on the bobbin being lifted from the lower to the higher groove, its toothed wheel is thrown out of gear with the wheel of the shaft *b*, *b*, and it remains at rest. Under each bobbin is seen the twisting-apparatus. This consists of a bobbin *c*, fixed on an upright spindle *d*, to which motion is communicated by a belt from the drum *f*, fixed on a horizontal shaft *g*, passing over a pulley on the bobbin spindle. The silk threads from these vertical bobbins are wound three or four times round a bent wire *h*, fixed to a bar, extending along the machine, passed through an eye in the end of each of these wires, carried through the eyes of the traverse-guides, and attached to the horizontal bobbins. On motion being given to the machinery, the vertical bobbins are made to revolve with a greater or less velocity, and the horizontal ones with a velocity so proportioned to the others, that they may only draw away the thread as it is twisted in the due degree. In figs. 13 and 14, we have represented, on a larger scale, a section and front view of these working parts: *a*, *a* is the bobbin from the cleaning-machine, *b* the fixed wire-guide round which the thread is carried, *c* the traverse-guide for spreading the thread over the bobbin, *d* the bobbin for receiving the twisted thread.

Fig. 12.

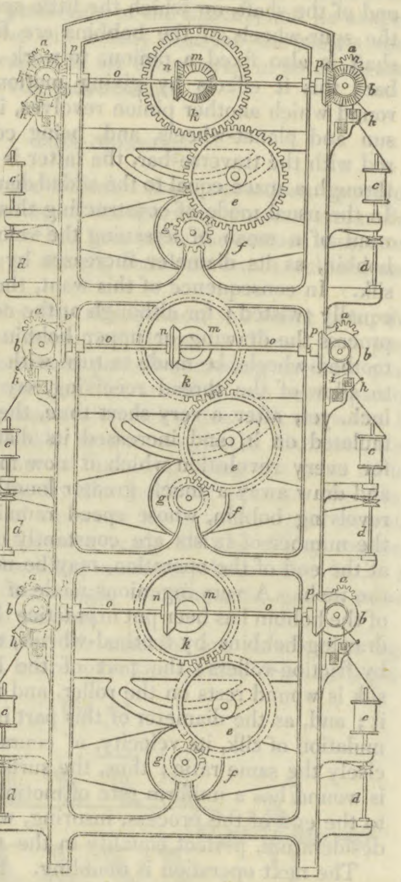

Fig. 13.

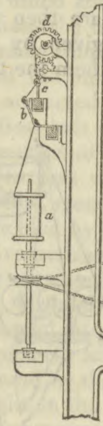

Fig. 14.

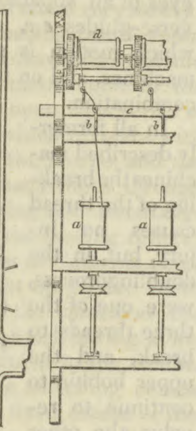


Motion is communicated to the different parts thus: On one end of the drum-shaft *g*, (fig. 12,) is fixed a fast and loose pulley, not seen in the drawing, driven by a belt from the main shaft which traverses the apartment; belts from the drum on the drum-shaft pass over the pullies of the vertical spindles *d*, and so give motion to the bobbins *c*; on the hither end of the drum-shaft is fixed the pinion *g*, which, through the intermediate wheel *e*, drives the spur-wheel *k*; on the axis of this last wheel is fixed the bevel-wheel *m*, giving motion to the bevel-wheel *n*, and thereby to the shaft *o*, which crosses the end of the machine; each end of this shaft carries a bevel-wheel *p*, which drives a bevel-wheel *h*, fixed on the end of the shaft, on which the little spur-wheels that drive the spur-wheels of the bobbins are fixed. On this last shaft is also fixed a pinion, to work the traverse guide-bar; this it effects by giving motion to a small wheel, round which another pinion revolves, in the manner of the sun and planet-wheels, and, being connected by a short rod with the traverse-bar, the latter is consequently moved through a space equal to the added diameters of the wheels. In the usual mode of constructing this machine, there is a want of a mean of lessening the velocity of the drawing-bobbin, as its diameter increases by the accumulation of silk. In consequence of this want, the thread is very unequally twisted; for although at the commencement of the process the drawing or upper bobbin may, by appropriate toothed-wheels, be made to turn with the velocity requisite to allow of the thread receiving, say twelve twists in the inch, yet, after a very short time, the silk will have accumulated on it, and increased its diameter so much, that for every revolution which it now makes, it will take up and draw away a much greater length of thread from the revolving bobbin, whose speed remains constant, so that the number of twists are constantly on the decrease, and, at the end of the operation, may be no more than eight in the inch. A very ingenious mode of equalizing the draw of the bobbin has been put in practice In place of driving the drawing-bobbins by toothed-wheels, they are here driven by friction-rollers; the part of the bobbin on which the silk is wound rests on the roller, and receives motion from it; and, as the diameter of this part increases by the accumulation of silk, its velocity, of course, diminishes in precisely the same ratio; thus, the surface on which the silk is wound has a uniform rate of motion from the beginning to the end of the process, insuring, what has ever been a desideratum, perfect equality in the twist of the thread.

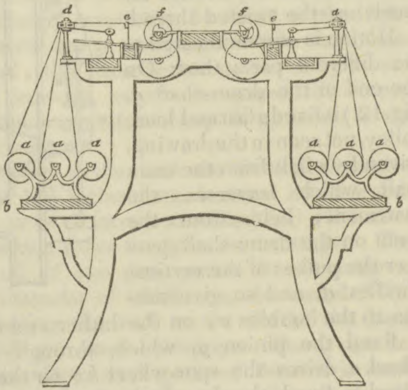
---

[1] The doffing board is an adoption from the cotton manufacture, and its use, as described above, is, we believe, peculiar to Scotland. Its chief advantage is, the check it affords against pilfering. When carried to the machine-room, the wires of the empty board are filled with empty bobbins, and, as the bobbins of the machine become charged with silk, they are exchanged for the empty ones of the board, which is again carried to the warehouse, that the bobbins may be assorted according to the quality of the silk. The filled bobbins are exchanged for empty ones, to be carried on the board to the winding machine room, and the same system is followed out in all the different stages of the operation.

Doubling.

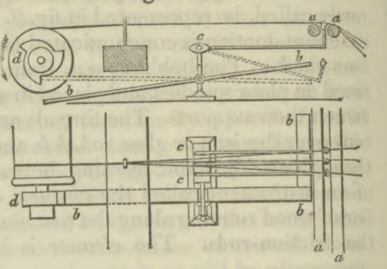
The next operation is doubling. Fig. 15 is an end view of the doubling-machine. In this machine the bobbins *a a a*, containing the spun silk, are arranged along the lower platform *b*, in little brackets capable of each containing three bobbins; from these the threads are carried over the guide-rods *d*, of which there are two on each side of the machine, and, after being passed through the eyes of an apparatus called the falling-wires, and the traverse-guides *e e*, are then attached to the bobbins *f f*, to which motion is given by friction-pullies, as in the first machines, and on them the threads are thus wound up in combination.

Fig. 15.



In all formerly described machines the breaking of the thread causes no injury, but, in the doubling process, were one of the three threads to break, and the upper bobbin to continue to revolve, the other two threads would be wound up separately, and so spoil the work; to prevent this is the use of the falling-wires described above, which, on the breaking of the thread, stop the bobbin until the damage is repaired. The subjoined sketch (figs. 16, 17), shews a side view and plan of this apparatus: *a a* are the two guide-rods, with the threads passing over them; between the rods are seen the eyelets of three bent wires, whose other extremities are hinged to a piece of brass at *c*. The threads are passed through these eyelets, and support the wires in the horizontal position shewn in the sketch. Hinged to the same supports as the wires is a brass lever, *bb*, bent at right angles horizontally under the wires; the straight end or tail of the lever is a little heavier than the bent end, and it consequently lies in the oblique position of our drawing. On the end of the bobbin is fixed a little ratchet-wheel, moving as indicated by the arrow. Now, when one of the threads sustaining the bent wires happens to break, the wire falls down on the bent part of the lever, which, by this additional weight, is depressed, and its opposite end consequently rises into the position shewn by the dotted line, and acts as a paul to the ratchet-wheel, effectually stopping the bobbin until the attendant has leisure to lift it out of its working-groove, repair the damaged thread, and again set it in motion.

Figs. 16, 17.



When the lighter kinds of silk have to be doubled, they would be injured by being made to drag round the heavy bobbins; therefore, for such kinds a modification of the apparatus is required. In place of the bobbins being placed horizontally in bearers, they are placed vertically on spindles, as shewn in figs. 12, 13, 14; the spindles project beyond the upper end of the bobbins, and carry a little wheel of hard wood, which is made to turn freely; this wheel has two flyers with eyelets at their extremities; the thread being put through these, and drawn by the upper bobbins, causes the light flyers to revolve round the vertical bobbin, and unwind the thread without straining it.

The next is the throwing machine. As this machine closely resembles the spinning-machine shewn in fig. 12, we here only sketch such a portion of it as will shew wherein they do not agree. Fig. 18 is an end view, and fig. 19 is a side view of one of the working parts: *a a* is a vertical bobbin with its loose flyer *b b*; the bobbin being driven by a band acting on the spindle pulley as in the spinning-machine; *c* is a traverse guide wire, through the eye of which the thread is passed; *d* a reel on which, in this case, the thread is wound into hanks as it is twisted by the revolution of the vertical bobbins. The traverse guide bars have, in this machine, a very short range of lateral motion, so as to confine each hank within a very narrow limit on the reel's surface. The motion of the reel can be so regulated in relation to that of the twisting bobbin, as in any way to modify the amount of twisting received by the thread.

Fig. 18.

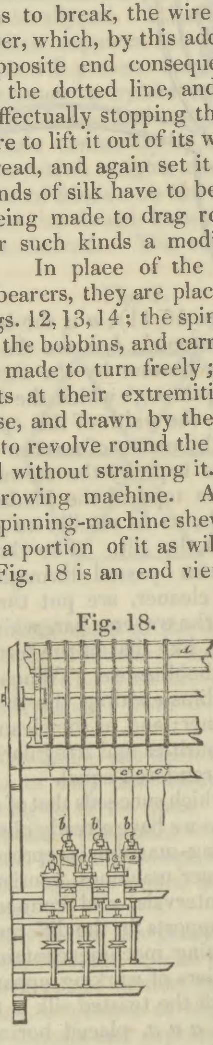


Fig. 19.

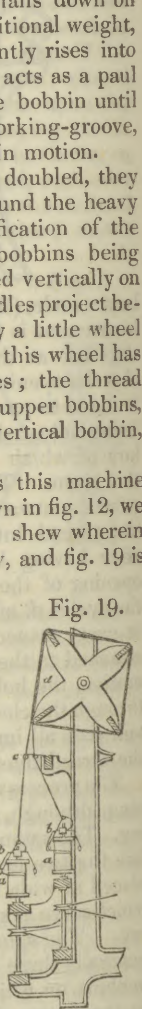


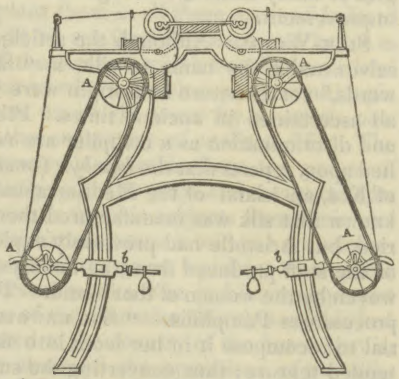
In the case of the heavier silk threads used for sewing, fringing, and the like, the doubling and throwing processes are both performed by one machine, called a throstle frame, which is similar to the machine of the same name used in the cotton and linen thread manufacture. The throstle, however, does not contain apparatus for reeling the silk, so, for this purpose, a subsidiary reel has to be used. This machine is automatic, in respect of stopping when a predetermined quantity of silk has been wound. One end of the axis of the reel is supported by a lever, whose fulcrum is at the centre of the machine; the other end of the axis has a fixed bearing. Motion is given to the reels by a pinion fixed on the end of its axis, being driven by a spur wheel on the main shaft; by raising the lever, which carries one end of the axis, the pinion would be withdrawn from the spur wheel, and the reel would necessarily cease to revolve. The machine is rendered automatic from the raising of the lever being effected by proper machinery at the very instant that the reel shall have wound up the length of silk predetermined, and by a detent locking it out of gear until the attendant shall have time to shift the apparatus which guides the silk to a new space on the reel.

We are sorry that we cannot present our readers with a more minute description of this machine, from the number of drawings which would be required to illustrate it.

Whether the hanks of silk have been reeled in the throwing-machine or on the automatic reel, they are afterwards treated in precisely the same manner. When the reels are filled with hanks, they are placed in a steam box, and subjected for a time to the action of the steam, to give the twisting of the thread a *set*, as it is termed; each skein or hank is then tied up separately in two places while yet on the reel, which is then carried to the proper apartment, and the hanks removed from it and bundled up.

The silk may be used without being deprived of its gum, and is termed *hard*, or it may be acted on by soap and water to deprive it of its gum, and reduce it to the *soft* state. In either of these states it may be put into the hands of the dyer, whose operations succeed those we have described. When the hanks come from the dyer they are again transferred to bobbins; the hard silk by a winding machine, similar to the one already described, the soft silk by the machine represented in fig. 20.[1] In this machine, in place of the swifts are substituted the small reels A A, the upper one fixed in position but turning freely on its axis, the lower one also turning freely on its axis, which is attached to a lever *b*, whose short end carries an adjustable weight, by means of which the hank of silk can be kept between the reels with the degree of tension suited to the strength of the thread. The operation of this machine will be understood from the winding machine already described, the only difference being, that the traverse guide has an equal and not an eccentric motion, so as to lay the silk regularly from end to end of the bobbin, and not heaped up in the centre as before. The transferring the silk to the bobbins finishes the operation of the silk throwster, from whose hands the silk passes into those of the warper, to prepare it for weaving.

Fig. 20.



The drawings of the machinery, by which we have illustrated our description of the throwing process, were, for the most part, made from machines constructed by Mr. Joseph Lomas of Glasgow, an engineer who has devoted much of his attention to the machinery used in this particular branch of manufacture.

Having thus traced the silk of the cocoons from its developement to the perfection of the filature, and its adaptation for the loom, we will briefly describe the means used for preparing the waste silk for the weaver, in so far as they are peculiar to the silk manufacture.

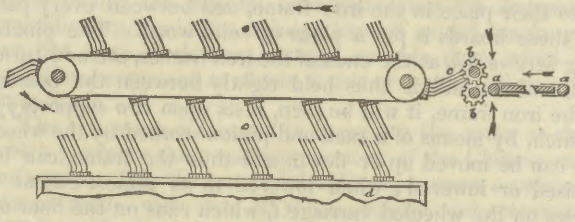
Silk Spinning.

Under this term are included those operations by which floss silk, and the refuse of the throwing process, are, under the name of waste, worked into yarns for coarser uses, such as the manufacture of shawls, Bandana handkerchiefs, and similar textures.

When received by the silk spinner, the waste is in the form of small balls of entangled filaments. These, as a preparatory step, he assorts in parcels according to their quality, and these different qualities are of course kept separate throughout the processes; after being assorted, the waste is hackled on a hand hackle, to disentangle the filaments, the instrument and manner of operating being the same as in flax-dressing. When, by the hackling process, the filaments of a quantity of the waste have, to a certain extent, been disentangled, they are ready for the *filling engine*, which is a kind of hackling machine, whose effect is, in a greater degree, to disentangle the filaments, and in some measure to lay them parallel.

The essential parts of this machine are sketched in fig. 21: *a a* is a feeding board, over the surface of which a travelling belt moves in the direction of the arrows, and carries forward to the feeding rollers *b b*, the hackled waste, which is laid on it. These rollers are fluted and move very slowly; between them the filaments from the feeding board enter, and are held fast, and at the same time drawn forward into the machine. As the ends of the filaments come to the other side of the rollers, they are acted upon by a series of iron teeth *c c*, fixed to an endless belt which revolves with a very quick motion in the direction of the arrows, and the teeth are consequently made to pass many times through the same portion of the filaments, clearing and disentangling them as they are slowly yielded by the feeding rollers; and as the ends of the successive portions of filaments cease to be held by the rollers, they are caught up by the teeth and carried round with them. Beneath the combs, as the travelling teeth are termed, a board *d* is fixed, having at intervals, along its surface, sets of teeth similar to the combs. When the filaments carried round by the travelling combs happen to fall off, they are caught on the fixed combs of the boards, and the regularity of their arrangement is not disturbed. When the combs, by repeated gleanings from the rollers, have become filled, the workman, with a pair of boards called *clutches*, removes from them, and from the teeth of the horizontal boards, their accumulation of filaments; these he carries to the next machine, called the *dressing frame*, which, like the filling engine, operates on the principle of combing. In this, however, the filaments are not gradually brought for-

Fig. 21.

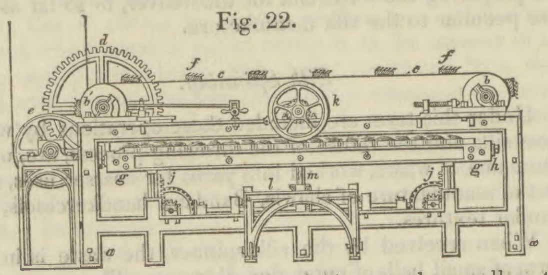


---

[1] In England, throwsters rarely if ever wind the soft silk, this duty devolving upon the manufacturer; but in Scotland, manufacturers being seldom provided with the requisite machinery, soft-silk winding is usually a part of the business of the throwster.

ward by rollers and yielded to the comb, but they are held firmly in their place by one end, while the combs travel over their surface, dragging away all impurities and all fibres which are shorter than the average length of the mass. Fig. 22 is a side view of the machine: *a a* is a fixed framing, at

Fig. 22.



each end of the frame is a roller *b b′*; over these rollers the endless web *c c* moves. Motion is communicated to the roller *b′* by the spur wheel *d*, on its axle being driven by a pinion on the axle of the pulley *e*, to which motion is given by a belt from a pulley of the main power shaft. The distance between the rollers *b b′* can be increased or diminished by a screw connected with *b*, so as to tighten or relax the endless web which travels round them. The endless web carries the combs *f f*, which, in this machine, are composed of a great number of short inclined teeth. Immediately below the top bar of the machine is seen the side of an iron frame *g g*, in which the silk to be operated on is fastened. Along the frame is seen the ends of a series of boards, whose lower edges are hinged together; between these boards, when opened like a book, the ends of the silk filaments from the filling engine are inserted, and the boards closed and put into their place in the iron frame, and between every pair of these boards is put a piece of solid wood. The pinching screws *h h*, at the ends of the iron frames, are now turned, and the silk is thus held tightly between the boards. The iron frame, it will be seen, rests upon two supports *j j*, which, by means of a rack and pinion worked by the wheel *k*, can be moved up or down, and thus the frame can be raised or lowered; when lowered to its utmost extent it rests on the wheeled carriage *l*, which runs on the floor on a railroad placed at right angles to the machine. The operation of the machine is as follows: The frame which contains the silk is lowered until it rests on the carriage, which is then drawn out at the side of the machine. The boards containing the silk are then put into their places and firmly compressed by the pinching screws; the carriage is now returned to its place under the combs, and by means of the wheel, the frame is adjusted so that the combs may act on the silk. The machine is then put in motion, and the combs, by repeatedly passing over the silk, disentangle and lay parallel the filaments and remove impurities. When the combing of one side of the filaments has been effected, the frame is again lowered, and the carriage withdrawn. The workman with a skewer turns over the silk so as to expose the uncombed side, wheels round the frame on its centre pivot *m*, and again runs the carriage into its place; again he raises the frame until within the scope of the combs, which constantly move in the same direction; and thus both sides of the material come to be thoroughly operated upon. The gleanings of the silk gathered by the combs, when accumulated, are screwed between the boards, and again subjected to the action of the machine; what is carried away by the combs in this operation is unfit for spinning, and is used, like the refuse of flax, for stuffing cushions and similar purposes.

When the filaments are by the dressing machine cleaned and laid parallel to each other, they are cut into lengths of about an inch and a quarter by the *cutting engine*, which operates upon the principle of chopping, and resembles the agricultural chaff machine. It is then operated upon by the scutcher, which is a modification of a similar machine used in the cotton manufacture. When it leaves the scutcher it resembles fine down, and is put into bags of a convenient size, and boiled for an hour and a half or so in soap and water, to deprive it of its gum; it is afterwards washed in pure soft water and again boiled, but not now for so long a period, this boiling being merely for the purpose of getting rid of impurities. It is then subjected to the action of a Bramah press, and when taken from the press, dried by means of a stove, after which it is cooled, and a second time passed through the scutching machine to fit it for carding. The carding is followed, as in the cotton manufacture, by the drawing and fly frames, to produce a rove, and these, by the spinning mill and the throstle, after which reeling and bundling complete the operations and fit the thread for the market.

Messrs. William Casey and Company, of Castle Mills, Edinburgh, have it in contemplation to introduce such alterations in the spinning of silk waste as will supersede the cutting, carding, and scutching processes. This improvement they mean to effect by adopting the principles of flax spinning, in place of treating the waste in the manner of cotton, the uncut filaments being in this case drawn into a sliver by a modification of the flax gill.

The art of silk waste spinning, we may observe, is still in its infancy, but is advancing rapidly to greater maturity. In 1814, the quantity of waste imported by Great Britain amounted to 28,996 lbs., and in 1836 it had reached to the amount of 1,509,334 lbs.

In closing this brief sketch of what is now an important branch of our manufacture, we beg to express our grateful acknowledgments to Messrs. Harvey, Brand, and Company, of Glasgow, whose beautiful silk-throwing factory of Blackhall, Paisley, was with the utmost liberality opened to our inspection; and it is our duty also to record our acknowledgments to Messrs. William Casey and Company, of Edinburgh, of whose contemplated improvements in silk waste spinning, we have before spoken; it is only through such liberality as these gentlemen have displayed, that knowledge of the arts can be disseminated, and the energies of many minds be brought to bear upon them to their improvement. (B. S.)

SILK-WORM. Although the article now known to ourselves under the name of silk, is "familiar as household words," yet its nature and origin were but obscurely, if at all ascertained in ancient times. Pliny, whose judgment and discrimination as a compiler are not greatly to be relied upon, reports that the *bombyx* (or silk worm) is a native of Kos, an island of the Mediterranean archipelago. It is known that silk was manufactured there at a very early period, but Aristotle had previously explained that *bombykia*, or the stuff produced from the bombyx, was respun and rewoven by the women of that island. The inventress of this process was Pamphilia. "She unwove the precious material to recompose it in her loom into fabrics of a more extended texture; thus converting the substantial silks of the Seres into thin transparent gauze, obtaining in measure what was lost in substance. Attempts have been made to rob the inventress of all the merit belonging to this process, by identifying the bombykia with the raw material, which it is said Pamphilia and her nymphs procured from Seres, and respun or wove into sericum or silk. But the fact of the reweaving rests upon too good authority to be doubted."[1]

Had Pliny been right in supposing that silk was a natural product of the island in question, it is by no means probable that so laborious a process as that of converting foreign wrought articles into threads for reweaving, would have been resorted to. Indeed, the Byzantine historians inform us, that prior to silk worms being imported into Constantinople in the sixth century, no one in that capital knew that silk was the produce of a caterpillar. Although Aristotle gives an account of the silk-worm, which he describes as a horned caterpillar, he does not indicate its native country. Assyria is named by Pliny as the original region of the bombyx, and he adds the extraordinary statement, that the stuff which the women of Rome unravelled and wove anew, was made from a *woollen* substance combed by the Seres from the leaves of trees, and that draperies formed from it were imported from the country of the Seres. These ancient people, we need scarcely remark, are generally believed to be the same with those we now name Chinese. Silk, in their language, is called *se* or *ser*, the latter term corresponding with that used by the Greeks, who, we cannot doubt, derived both the material itself, and the name by which it was designated, from the Chinese nation. According to Latreille, the city of Turfan, in Little Bucharia, was for a long time the rendezvous of the western caravans, and the chief entrepôt of the Chinese silks. It was the metropolis of the Seres of Upper Asia, or of the Serica of Ptolemy, situate, according to that author, between the Ganges and the Eastern Ocean. Hence the *Serica vestis* of the Romans, and the word *Sericum*, their name for silk.

---

[1] Cabinet Cyclopædia, xxii. 5

This substance was but slightly known in Europe before the time of Augustus, and in the days of Aurelian was valued at its weight in gold. This was probably owing to the mode in which it was procured by the merchants of Alexandria, who had no direct intercourse with China, the chief, if not the only country in which the silk-worm was then reared. Though so highly lauded both by Greek and Roman writers, it was in frequent use for many centuries before any certain knowledge was obtained either of the country from which the material was derived, or of the means by which it was produced. By some it was supposed to be a fine down adhering to the leaves of trees and flowers; by others it was regarded as a delicate kind of wool or cotton,[1] and even those who had some idea of its insect origin, were incorrectly informed of the mode of its formation.[2] The court of the Greek emperors, which surpassed even that of the Asiatic sovereigns in splendour and magnificence, became profuse in its display of this lustrous ornament; but as the Persians, from the advantages which their local situation gave them over the merchants from the Arabian Gulph, were enabled to supplant them in all those marts of India to which silk was brought by sea from the East, and had it in their power to cut off the caravans which travelled over land to China through their northern provinces, Constantinople thus became dependent on a rival power for an article now deemed essential to the enjoyment of civilized life. The Persians, with the rapacity inseparable from the power of monopolists, exorbitantly raised its price, and many attempts were made by Justinian to free his subjects from their exactions. An accidental circumstance is said to have accomplished what the wisdom of the great legislator was unable to achieve. Two Persian monks, who had been employed as missionaries in one of the Christian churches established in India, had penetrated to the country of the Seres, that is, to China, where they observed the operations of the silk-worm, and acquired a knowledge of the art of man in working up its produce into so many rich and costly fabrics. The love of lucre, mingled, it is said, (though perhaps a single motive may suffice,) with a feeling of indignation that so valuable a branch of commerce should be enjoyed by unbelieving nations, induced them to repair to Constantinople, where they explained to the emperor the true origin of silk, and the various modes by which it was prepared and manufactured. Encouraged by the most liberal promises, they undertook to transport a sufficient supply of these extraordinary worms to Constantinople, which they effected by conveying the eggs of the parent moth in the interior of a hollow cane. They were hatched, it is alleged, by the heat of a dunghill, and the larvæ were fed with the leaves of wild mulberry. They worked, underwent their accustomed metamorphoses, and multiplied their kind according to use and wont, and in the course of time have become almost universally cultivated throughout the southern countries of Europe, thus effecting an important change in the commercial relations which had so long existed between our continent and the east.[3]

The cultivation of the silk-worm spread, at the period of the first crusades, from the Morea into Sicily, the kingdom of Naples, and several centuries afterwards, more especially under the administration of Sully, into France, to which kingdom it is well known to be now a source of great wealth. It is indeed curious to consider how the breeding of a few millions of small caterpillars should occasion such a disparity in the circumstances, or at least in the outward shew, of different tribes of the human race. When the wife and empress of Aurelian was refused a garment of silk on account of its extreme costliness, the most ordinary classes of the Chinese were, we doubt not, clad in that material from top to toe; and although, among ourselves, weekday and holiday are now alike profaned by uncouth forms, whose vast circumference is clothed in silk attire, yet our James the Sixth was forced to borrow a pair of silken hose from the Earl of Mar, that his state and bearing might be more effective in the presence of the ambassador of England, "for ye would not," said the uncouth pedant, "that your king should appear as a scrub before strangers." Queen Elizabeth, in the third year of her reign (1560), was highly gratified by receiving from her silk-woman, Mrs. Montague, a pair of knit black-silk stockings, with which she is said to have been so delighted, as never afterwards to have worn those of cloth. Even Henry the Eighth, notwithstanding his expensive magnificence, could not indulge himself as did his daughter, but wore cloth hose, except on gala days, when he sometimes contrived to obtain a pair or two of silken ones from Spain.

The silk-worm cultivated in Europe is the same as that which produces the greater proportion of the Chinese manufacture. It is the larva of the *Bombyx mori*, a pale coloured moth, with two or three obscure and transverse streaks, and a lunate spot on the superior wings. The caterpillar feeds on the leaves of the mulberry, and before assuming the chrysalis form, it spins a protecting covering in the shape of an oval cocoon, of a close tissue of the finest silk, usually of a yellow colour, but sometimes white. The filament does not form regular concentric circles round the interior surface of the cocoon, but is spun as it were in spots, going backwards and forwards with a wavy motion. This apparently irregular manner of proceeding is plainly perceptible when the silk is wound off the ball, which does not make more than one or two entire revolutions, while ten or twelve yards of silk are being transferred to the reel.[4] The caterpillar casts and renews its skin several times before it commences to spin, and when full grown, it measures from two and a half to three inches. The principal points to be attended to in its cultivation, are regular feeding three or four times a-day, good ventilation, and a rather high temperature, especially at the period of spinning, say 70° Fahrenheit. It lives and spins though fed only on lettuce leaves, but their true and natural food is the mulberry, especially the white kind, called by botanists *Morus alba*.

The important tree just named, is a native of China, from whence it is believed to have been transferred to India, Persia, and Asia Minor. It was introduced at Constantinople during the sixth century, in the reign of Justinian, in connection, no doubt, with the importation of the worms themselves. It was afterwards introduced into Greece, and the name *Morea*, by which the Peloponnesus is now distinguished, is ascribed by many authors to the vast quantity of mulberry trees there cultivated In 1130, Roger, king of Sicily, having conquered many portions of the Morea, transported the white mulberry into his own kingdom, along with a supply of silk worms, and of artizans who understood their cultivation, and the manufacture of their natural product. About the year 1493, in the reign of Charles the Eighth, some nobles who had accompanied that Prince into Italy, brought the mulberry from Naples, and planted it in the environs of Montélimart. Not many years have gone by since those parent trees, the source of so rich a branch of commercial industry to France, were exhibited with an almost religious veneration. The mulberry was cultivated not only in the south of France, but Henry the Fourth brought a great many to Paris, which he planted in the gardens of the Tuilleries, where an establishment was founded for the rearing of the worms, and the preparation of their silk. No vestige of this plantation now remains.

It was long supposed that the cultivation of the white mulberry required a high temperature, but the contrary is proved by the fact of its thriving well in so many northern provinces of Germany. Even in Russia it is reared with considerable success. In France, however, it is not raised in large quantities with a view to the feeding of silk-worms, except in the central and southern provinces, as far north as the environs of Lyons. Government does not seem to have held out any encouragement to its extension, otherwise we doubt not that both the tree and caterpillar might be more extensively and abundantly spread over the more northern departments. The white mulberry is by no means nice in regard to the constituent character of its soil, and it is known to flourish in a great variety of situations. At the same time, the nature both of soil and situation seems to exercise considerable influence over the produce of the caterpillars which feed upon its leaves; the silk being finer, ampler, and more resistant, in proportion as the plant is successfully cultivated in a dry and rather elevated position. In the south of France it is customary to cut off all the medium-sized branches every year, with a view to facilitate the production of a greater number of young shoots, these bearing the largest and most numerous leaves. The leaves of the black mulberry (*Morus nigra*), and in general those of all the other species of the genus, are adapted to the nourishment of the silk-worm. But not only are they apparently less grateful to their taste, but they actually produce a silk much inferior both in quantity and quality.

We have said that the silk-worm cultivated in Europe is the same as that which produces the greater proportion of the Chinese manufacture. But in Bengal and other parts of India, valuable silk is procured from the cocoons of other species of moth. The first of these is described by Dr. Roxburgh under the title of *Phalæna paphia*, and occurs in such abundance over many parts of Bengal, and the adjoining provinces, as to have afforded to the natives, from time immemorial, an abundant supply of a very durable, though coarse, and dark-coloured silk, called *Tusseh*, much used by the Brahmins, and other sects of Hindoos. This species, however, cannot be domesticated; so the hill people go into the jungles, and when they perceive the dung of the caterpillars under a tree, they immediately search for them among the branches, and carry off what they require. These they distribute on the Asseen trees (*Terminalia alata glabra* of Roxb.), and as long as they continue in the caterpillar state, the Pariahs guard them from birds by day, and from bats by night. The natural food of this species is the *Byer* tree of the Hindoos, called *Rhamnus jujuba* by botanists. The Jaroo cocoons are produced from a rare variety of the kind just mentioned. This tusseh silk-worm moth appears to be synonymous with *Bombyx mylitta* of Fabricius, and is figured by Drury.[1] The Arrindy silk-worms, however, belong to an entirely different species, *Phalæna cynthia* of the last named author.[2] It seems to be peculiar to two districts in the interior of Bengal, viz. Runpore and Dinagepore, where it is reared in a domestic state. The food of this kind of silk-worm consists entirely of the leaves of the common *Ricinus*, or Palma Christi, which the natives call *Arrindy*, and hence the name by which the insect is itself distinguished. The cocoons in general are about a couple of inches in length, three inches in circumference, and pointed at both ends. They are of a white or yellowish colour, and their texture is extremely soft and delicate. The filament, indeed, is so extremely fine, that the silk cannot be wound off, but must be spun like cotton. The yarn is wove into a kind of coarse white cloth, of a seemingly loose texture, but of such extreme durability, that the life of one person seldom suffices to wear out a garment of it; so that the same piece frequently descends from parent to child. It must always be washed in cold water.[3]

The only other species with which we are acquainted is that alluded to by Mr. Arthur Young, in an extract of a letter published in the *Annals of Agriculture*. It has been introduced into our Eastern possessions for a considerable number of years. "We have obtained," says the writer of the letter, "a monthly silk-worm from China, which I have reared with my own hands, and in twenty-five days have had the cocoons in my basins, and by the twenty-ninth or thirty-first day, a new progeny feeding in my trays. This makes it a mine to whoever would undertake the cultivation of it."

The practice of rearing silk worms in this country is usually followed rather as an amusing occupation than for purposes of gain. The female moth is induced to lay her eggs upon sheets of paper, to which they adhere by a natural viscosity. The period of hatching may be hastened or retarded by a higher or lower temperature, and the chief point for the breeder to bear in mind is, that the worms should not make their appearance till an abundance of natural food is near at hand. The eggs are at first of a very pale hue, but such as are to produce worms speedily become of a bluish grey colour; the unproductive ones continuing of a pale yellow. As there are tricks in all trades, the foreign dealers often favour their old useless eggs with a wash in dark-coloured muddy wine, which gives them for a time a deceptive healthy aspect. A stove-room, or other apartment, with a temperature of 64° will suffice for the hatching of eggs, and the heat may afterwards be raised with advantage a few degrees every other day, for about ten days, but not so as to exceed about 80°. They will, however, thrive well enough in summer in any comfortably kept apartment, though a continuous warmth by night as well as by day is of great advantage. Whatever broods are hatched at the same period, should be kept together, and those of different ages ought never to be fed in the same trays.

The best and simplest apparatus for keeping silk worms is that proposed by Mr. Swayne. It consists of an open quadrangular wooden frame, about four feet two inches high, provided with eight uncovered slides or drawers a few inches apart from each other, and which, moving in a groove or ledge, can easily be shifted out or in. The upper slide is made of paper, and is devoted to the reception of the newly hatched worms, which it is desirable to feed at first with young and delicate leaves, chopped into small pieces. The flooring of the second and third slides is made of catgut, the reticulations being about the tenth part of an inch asunder. In these the worms are placed during what may be called the second and third stages. The five remaining slides are made of wicker-work or netting, and in them the insects are distributed "fewer and far between," as they increase in size. Beneath every drawer except the uppermost, which is itself made of paper, additional paper slides should be placed to receive the dung, and the worms must not be kept any longer in the second and third drawers, so soon as the litter alluded to becomes so large as to stick in the catgut meshes, without falling through upon the paper slides beneath. By means of these additional slides, this litter may be removed any time the worms are fed, without the necessity of handling the latter. When the fresh food is placed in the drawers they will speedily creep upon it, and any remnants of old leaves can be picked up by a pair of small pincers.

[3] See Account of the Tusseh and Arrindy silk-worms of Bengal, by William Roxburgh, M.D. Linn. Trans. viii. 33; and British India (in Edin. Cab. Library), iii. 154.

Silk worms ought to be fed with regularity at least four times a-day; additional or intermediate meals being given when any extraordinary appetite is manifested. The duration of the lives of these animals depends, to a certain extent, upon temperature and locality; warmth, well kept quarters, and abundance of food, being found to hasten the spinning process. All these things should be very sedulously attended to by those who rear silk worms in large quantities with a view to profit, time being so important an element in all commercial undertakings.

When the silk worm makes its first appearance, it is of a dark colour, and measures only one or two lines in length; after the lapse of eight days, it is attacked by a lethargic sickness, which will cause the heart of the young or inexperienced breeder to despond, but he need fear no evil, for this is only an unavoidable symptom of the ordinary ongoings of nature. The creature is about to cast its skin, and for about three days it remains motionless, refusing food. On the termination of this period the old skin opens at the anterior end, the fore-legs are disengaged, and the new and delicately attired worm escapes forth, to enjoy itself once more on pastures green. It had previously exuded a peculiar fluid, and had also, by means of a few silken strings (how provident is benign nature!) fastened down its old and useless coat, that it might not be dragged after it when the hour of delivery has arrived. This coating is so complete, that even the skin which covers the eyes and teeth is thrown away. Immediately after this renewal, the body of the worm appears pale and somewhat wrinkled, the new coat being made full size to admit of future growth; but the latter attribute speedily disappears. It feeds freely for five additional days, during which it grows to about half an inch in length, and is then seized by its second sickness, and again casts its skin. Then succeed other five days of feasting, in the course of which it increases to three quarters of an inch, when it sickens a third time, and acquires in a similar manner a third suit of clothes. Again five days of feeding; again a removal of the outer garment, or a fourth casting of the skin. The caterpillar now measures from an inch and a half to two inches long, and for a continuous period of about ten days it eats voraciously, and increases greatly both in length and thickness. On the expiry of this last-mentioned period, it has attained the full stature of a silk-worm, being from two and a half to three inches long. Its desire for food abates, it nibbles and wastes its leaves, then ceases to eat, and becomes restless and uneasy, moving circularly from side to side, owing to some instinctive feeling of desire to secure a quiet haven in which to spin its silken shroud. Its colour is now of a palish green, with a mingling of a deeper hue. In the course of about twenty-four hours from the time of its having ceased to feed, the silky texture becomes abundantly supplied to its interior reservoirs; the green colour disappears, the body becomes glossy, and somewhat transparent towards the neck. Previous to spinning, the general dimensions rather decrease than otherwise, but greater firmness of substance is acquired.

When the desire to spin is thus unequivocally manifested, art must come in aid of nature. Our own method formerly was (we worked, however, in this department on a narrow scale,) to supply our caterpillars with small twisted paper bags, open at one end, such as any old woman may use on a Saturday night to carry from the grocer's her solitary ounce of tea. Into each of these would creep a single caterpillar, and weave his golden woof incessantly, till the loved work was done. But those who rear extensively, supply their completed caterpillars with small twigs or branches of broom, heath, or any other brushwood, which happens to unite tenderness and tenacity.

Great attention must now be paid in regard to keeping up a warm temperature. The observations of a writer in the fifth volume of the Society for the Encouragement of Arts, amply illustrate this important point. He had successfully reared thirty thousand silk-worms, when in the beginning of July, just as they were about to spin, there came a chilly north-east wind, and many assumed the chrysalis state, without making any attempt to form a protecting covering. On examining these individuals, it was apparent that their silken reservoirs had been congealed by cold, so that the insects were unable to draw out the filaments in their usual slender state, their own capacity of movement and exertion being no doubt at the same time chilled. Even when they have commenced to spin, or have made some progress in their labours, they will cease if exposed to cold, and if the surrounding web is still of sufficient transparency, they may be seen lying idle and inactive in the interior of their cocoons. But if the temperature is raised, they will immediately resume their work. A heat as high as 70° is thought advisable at this time.

These beautiful silken coverings, or cocoons as they are called, are generally completed in three or four days. They are commenced by the formation (among the twigs or in paper bags, as the case may be) of a loose decomposed structure of an oval form, made of what is denominated *floss* silk. Within this, in the course of the ensuing days, the firmer cocoons are completed. These are rounded somewhat oval balls, varying in tint, but usually more or less of a golden hue, though sometimes white. Those of a bright yellow hue yield the greater weight of reeled silk, but as the finer colouring substance is contained chiefly in the gum which is boiled out before weaving, less advantage is reaped by the grower. Raw silk, of a pale colour, is moreover preferred, on account of its better reception of certain dyes. The included worm, having finished its labour, casts its skin once more, but never appears again as a caterpillar, as it now assumes that rounded shapeless form termed *chrysalis*. The cocoons may be selected for reeling in about a week, and then comes the ungrateful and ungracious task of destroying the peaceful tenants of the tomb. This is variously accomplished, either by exposure (in sunny climates,) for some hours to unclouded solar light and heat; by steam; or by placing the cocoons in a temperature corresponding to that of an oven from which loaves have just been withdrawn after being baked.

If not killed, the chrysalis remains in its naturally dormant state for a longer or shorter time, in accordance with the clime in which it has had its birth. In eastern countries this is not more than eleven days; in the most southern parts of Europe from eighteen to twenty; in France about three weeks; in England, if unaided by artificial means, about a month. After these respective periods, according to climate, whether natural or acquired, the perfect moth emerges, and the reason for destroying the chrysalis is this, that in emerging *she* (the moth) destroys the silk, under the impression probably, that she may do what she likes with her own. A few, however, are of course spared for the sake of a future progeny, sound cocoons being selected, and in equal numbers as to sex, those containing the males being sharper or more pointed at the ends.

Such as have been killed for reeling are, before the commencement of that process, placed in warm water, so that their gummy nature may be partly softened, but not dissolved. The length of silken thread which may be unwound from a single cocoon, although it has been ridiculously exaggerated by Isnard and other writers, is in truth astonishing. Count Dandolo found it occasionally to exceed 600 yards; Miss Rhodes of Yorkshire mentions that one of her largest cocoons yielded 404 measured yards; and Pullein considers the average length to be about 300 yards. From data given by the first named author it was found, that to obtain one pound of reeled silk, twelve pounds of cocoons are required; that 2800 worms would be necessary to produce that amount of cocoons; and that to feed these caterpillars, 152 pounds of mulberry leaves must be collected.

As we write this brief notice rather for the amateur than the artizan, the mention of the above named tree reminds us of the propriety of stating, that as mulberry leaves cannot be easily obtained in Britain in required abundance, the best substitute is *lettuce*.

SILLA, a large town on the Niger, by which the travels of Mr. Park were bounded towards the east. He gives no particular description of the place, which his health and spirits permitted him not to survey, but assigns the reasons by which he was induced to proceed no farther. On his arrival, he was allowed to remain under a tree, till it was quite dark, surrounded by hundreds of people. But their language was extremely different from the other parts of Bambarra; and he was given to understand, that in his progress eastward, the Bambarra tongue was very little understood, and that, on his reaching Jenné, he would find the greater part of the inhabitants accustomed to speak a different language. He had now become the prey of sickness, exhausted with hunger and fatigue, half naked, and without any article of value to procure for himself provisions, clothes, or lodging, on which account he resolved to return, finding that to prosecute his journey further in that direction was wholly impracticable. Silla, acording to the latest map of Africa, is in 14. 48. N. lat. and 1. 24. W. long.

SILVERING, the covering of any thing with silver It is usual to silver metals, wood, paper, and the like, which is performed either with fire, oil, or size. Metal-gilders silver by the fire; painter gilders all the other ways.

To silver copper or brass. First cleanse the metal with aquafortis, by washing it lightly, and immediately throwing it into pure water; or by heating it red hot, and scouring it with salt and tartar, and some pure water, with a small wire brush. Secondly, Dissolve some silver in aquafortis, in a broad-bottomed glass vessel, or of glazed earth; then evaporate away the aquafortis over a chaffing dish of coals. Thirdly, Put five or six times its quantity of water, or as much as will be necessary to dissolve it perfectly, on the remaining dry calx; evaporate this water with the like heat; then put more fresh water, and evaporate again; and, if need be, the third time, making the fire towards the latter end so strong as to leave the calx perfectly dry, which, if your silver is good, will be of a pure white. Fourthly, Take of this calx, common salt, crystals of tartar, of each a like quantity or bulk, and mixing well the whole composition, put the metal into pure water, and take of the said powder with your wet fingers, and rub it well on, till you find every little cavity of the metal sufficiently silvered over. Fifthly, If you would have it richly done, you must rub on more of the powder; and, in the last place, wash the silvered metal in pure water, aud rub it hard with a dry cloth.

SIMEON *of* DURHAM, the contemporary of William of Malmsbury. He took great pains in collecting the muniments of our history, especially in the north of England, after they had been scattered by the Danes. From these he composed a history of the kings of England, from A. D. 616 to 1130, with some smaller historical pieces. Simeon both studied and taught the sciences, and particularly the mathematics, at Oxford; and he became precentor of the church at Durham, where he died, probably soon after the conclusion of his history, which was continued by John, prior of Hexham, to the year 1156.

SIMFEROPOL, called formerly Akhmetschet; a city of the province of Tauria in Russia, the capital of that province as well as of a circle of the same name. It stands on an elevated plain, surrounded on all sides by mountains, on the banks of the river Salair. It is divided into the new and the old city; the former is regularly laid out, and contains a public school, and a few offices of the government. The latter is surrounded with high walls, and has narrow and crooked streets without pavement, and is chiefly inhabited by the Tartars. The united towns contain about 1000 houses, and nearly 20,000 inhabitants, from a great variety of nations. It has a Russian, a Greek, and an Armenian church, and three Tartar mosques, with several baths. Lat. 44. 59. Long. 34. 1. 5. E. It is 1458 miles from St. Petersburg. It is considered to be unhealthy in summer, owing to a deficiency of good water, and the filthy habits of the Tartar population.

SIMILE, or SIMILITUDE, in *Rhetoric*, a comparison of two things, which, though different in other respects, yet agree in some one. The difference between a simile and comparison consists in this, that the simile properly belongs to whatever we call the quality of a thing, and the comparison to the quantity.

SIMILOR, a name given to an alloy of red copper and zinc, made in the best proportions, to imitate silver and gold.

SIMOGA, a fortified town of the south of India, in the province of Mysore, and district of Bednorr, situated on the Zunga or Zoom river. The fortifications are not strong, and are incapable of resisting a regular attack. It has a manufacture of cotton cloth in the neighbourhood. It contains the temple and convent of Kudali Sivami, the high priest of a sect of Mahratta Brahmins. In 1790, an action was fought near this place, between Purseram Bhow and Mahommed Reza, in which the Mahrattas were assisted by a detachment of British troops under Captain Little, who gained the battle. At this time Simoga contained 6000 houses, which were utterly destroyed by the Mahrattas. It was again destroyed in 1798, but has since considerably recovered its wealth and population. Long. 75. 35. E. Lat. 13. 51. N.

SIMON MACCABEUS, a celebrated leader, and high-priest of the Jews, who, after rendering the most important services to his country, was at last treacherously murdered by his son-in-law.

SIMON Magus, or the Sorcerer, was a native of Gitton, a village of Samaria. According to the usual practice of the Asiatics of that age, he visited Egypt, and there probably became aquainted with the sublime mysteries taught in the Alexandrian School, learning those theurgic or magical operations, by means of which it was believed that men might be delivered from the power of evil demons. Upon his return into his own country, the author of the *Clementine Recognitions* relates, that he imposed upon his countrymen by high pretensions to supernatural powers. St. Luke attests, that this artful fanatic had bewitched the people of Samaria, giving out that he was some great one; and that he obtained such general attention and reverence in Samaria, that the people all gave heed to him, from the least to the greatest, saying "This man is the great power of God."

By the preaching of Philip the Deacon, he was, with other Samaritans, converted to the Christian faith, and admitted into the infant church by the ordinance of baptism. His conversion, however, seems not to have been real; for, upon seeing the miraculous effects of the laying on of the apostles' hands, he offered them money, saying, "Give me also this power, that on whomsoever I lay hands he may receive the Holy Ghost." He probably thought Peter and John magicians like himself, but better skilled in the art of deceiving the multitude.

Being sharply reproved for this impiety, he seems by his answer to have been made sensible of his sin; but his repentance, if sincere, was of short duration. Returning to his former practices of imposture, he travelled through various provinces of the empire, opposing the progress of the gospel; and arriving at Rome, he led astray vast numbers of people by his pretended miracles. How long he lived in that metropolis of the world, or in what manner he died, we have no accounts that can be depended on. The Christian writers tell us, that being raised in the air by two demons, he was deprived of their support by the prayers of St. Peter and St. Paul, and falling, broke his legs. By some he is thought to have been the person mentioned by Suetonius, who having undertaken to fly in the presence of Nero, fell to the ground with such violence, that his blood spurted up to the gallery where the emperor was sitting.

The sum of this impostor's doctrine, divested of allegory, was, that from the Divine Being, as a fountain of light, flow various orders of æons, or eternal natures, subsisting within the plenitude of the divine essence; that beyond these, in the order of emanation, are different classes of intelligences, amongst the lowest of which are human souls; that matter is the most remote production of the emanative power, which, on account of its infinite distance from the Fountain of Light, possesses sluggish and malignant qualities, which oppose the divine operations, and are the cause of evil; that it is the great design of philosophy to deliver the soul from its imprisonment in matter, and restore it to that divine light from which it was derived, and that for this purpose God had sent him as one of the first æons amongst men. To his wife Helena he also ascribed a similar kind of divine nature, pretending that a female æon inhabited the body of this woman, to whom he gave the name of Εννοια, or *Wisdom;* whence some Christian fathers have said, that he called her the *Holy Spirit.* He also taught the transmigration of souls, and denied the resurrection of the body.

Simon, *Richard,* was born at Dieppe on the 15th May 1638. He began his studies amongst the priest of the Oratory in that city, but in a short time quitted their society. From Dieppe he went to Paris, where he made great progress in the study of the oriental languages. Some time afterwards he joined the society of the Oratory again, and became a priest of it in 1660. In 1670 he published some pieces of a smaller kind; and in 1678 his Critical History of the Old Testament appeared, but was immediately suppressed by the intrigues of the gentlemen of Port-Royal. It was reprinted the year after, and its excellence soon drew the attention of foreigners; an edition of it was accordingly published at Amsterdam in Latin, and in London in English. He died at Dieppe in 1712, at the age of seventy-four.

He certainly possessed a vast deal of learning. His criticism is exact, but not always moderate; and there reigns in his writings a spirit of novelty and singularity which raised him a great many adversaries. The most celebrated of these were Le Clerc, Vossius, Jurieu, Dupin, and Bossuet. Simon wrote an answer to most of the books that were published against him, and displays a pride and obstinacy in his controversial writings which do him little honour. He was the author of a great many books. The following are the principal, viz:—1. The Ceremonies of the Jews, translated from the Italian of Leo of Modena, with a supplement concerning the sects of the Caraites and Samaritans; 2. The Critical History of the Old Testament; 3. Critical History of the Text of the New Testament; 4. Critical History of the Versions of the New Testament; 5. Critical History of the principal Commentators on the New Testament; 6. Inspiration of the Sacred Books; 7. A translation of the New Testament, which was censured by Cardinal Noailles and by Bossuet; 8. The History of the Rise and Progress of Ecclesiastical Revenues, which is commended by Voltaire, as is his Critical History of the Old Testament; 9. A new select Library, pointing out the good books in various departments of literature, and the use to be made of them; 10. Critical History of the Belief and Customs of the nations on the Levant; and, 11. Critical Letters.

Simonides.

SIMONIDES, the name of several poets celebrated in antiquity. But by the Marbles it appears that the eldest and most illustrious of them was born in the fifty-fifth Olympiad, 538 years before Christ, and that he died in his ninetieth year, which nearly agrees with the chronology of Eusebius. He was a native of Ceos, one of the Cyclades, in the neighbourhood of Attica, and the preceptor of Pindar. Both Plato and Cicero give him the character of a good poet and musician, and speak of him as a person of great virtue and wisdom. Such longevity gave him an opportunity of knowing a great number of the first characters in antiquity with whom he was in some measure connected. It appears in Fabricius, that Simonides was contemporary with Pittacus of Mitylene, Hipparchus, tyrant of Athens, Pausanias, king of Sparta, Hiero, tyrant of Syracuse, as well as with Themistocles, and with Alevades, king of Thessaly. He is mentioned by Herodotus; and Xenophon, in his *Dialogue upon Tyranny,* makes him one of the interlocutors with Hiero king of Syracuse. Cicero alleges, what has often been quoted in proof of the modesty and wisdom of Simonides, that when Hiero asked him for a definition of God, the poet required a whole day to meditate on so important a question. At the end of that time, upon the prince putting the question to him, he asked two days' respite, and in this manner always doubled the delay each time he was required to answer it; till at length, to avoid offending his patron by more disappointments, he frankly confessed that he found the question so difficult, that the more he meditated upon it, the less was his hope of being able to solve it.

In his old age, perhaps from seeing the respect which money procured to such as had lost the charms of youth, and the power of attaching mankind by other means, he became somewhat mercenary and avaricious. He was frequently employed by the victors at the games to write panegyrics and odes in their praise, before his pupil Pindar had exercised his talents in their behalf. But Simonides refused to gratify their vanity in this particular, till he had first tied them down to a stipulated sum for his trouble; and upon being upbraided for his meanness, he said, that he had two coffers, in one of which he had for many years put his pecuniary rewards, whilst the other was for honours, verbal thanks, and promises, that the first was pretty well filled, but the last remained always empty; and he made no scruple to confess in his old age, that of all the enjoyments of life, the love of money was the only one of which time had not deprived him.

He was frequently reproached for this vice; but he always defended himself with good humour. Upon being asked by Hiero's queen, whether it was more desirable to be learned or rich, he answered, that it was far better to be rich; for the learned were always dependent on the rich, and waiting at their doors; whereas, he never saw rich men at the doors of the learned. When he was accused of being so sordid as to sell part of the provisions with which his table was furnished by Hiero, he said he had done it in order "to display to the world the magnificence of that prince and his own frugality." To others he said, that his reason for accumulating wealth was, that "he would rather leave money to his enemies after death, than be troublesome to his friends whilst living."

He obtained the prize in poetry at the public games when he was fourscore years of age. According to Suidas, he added four letters to the Greek alphabet, and Pliny assigns to him the eighth string of the Lyre; but these claims are disputed by the learned.

His poetry was so tender and plaintive, that he acquired the cognomen of ***Melicertes***, sweet as honey, and the tearful eye of his muse was proverbial. Dionysius places him amongst those polished writers who excel in a smooth volubility, and flow on like plenteous and perennial rivers, in a course of even and uninterrupted harmony.

There is a second great poet of the name of Simonides recorded on the Marbles, and supposed to have been his grandson, who gained, in 478 before Christ, the prize in the games at Athens.

SIMONY, is the corrupt presentation of any one to an ecclesiastical benefice for money, gift, or reward. It is so called from the resemblance it is said to bear to the sin of Simon Magus, though the purchasing of holy orders seems to approach nearer to his offence. It was by the canon law a very grievous crime; and is so much the more odious, because, as Sir Edward Coke observes, it is ever accompanied with perjury, the presentee being not to commit simony.

SIMOOM, a hot wind which blows occasionally in the deserts of Africa, and probably in other widely extended countries parched in the same manner by a vertical sun. Its effects on the human body are dreadful. If inhaled in any quantity, it produces instant suffocation, or at least leaves the unhappy sufferer oppressed with asthma and lowness of spirits. The approach of this awful scourge is indicated by a redness in the air, well understood by those who are accustomed to journey through the desert; and the only refuge which they have from it, is to fall down with their faces close to the ground, and to continue as long as possible without drawing in their breath. Mr. Bruce, who, in his journey though the desert, suffered from the simoom, gives the following graphical description of this visitation. "At eleven o'clock, while we contemplated with great pleasure the rugged top of Chiggre, to which we were fast approaching, and where we were to solace ourselves with plenty of good water, Idris our guide cried out, with a loud voice, fall upon your faces, for here is the simoom. I saw from the south-east a haze come, in colour like the purple part of the rainbow, but not so compressed or thick. It did not occupy twenty yards in breadth, and was about twelve feet high from the ground. It was a kind of blush upon the air, and it moved very rapidly; for I scarce could turn to fall upon the ground with my head to the northward, when I felt the heat of its current plainly upon my face. We all lay flat on the ground as if dead, till Idris told us it was blown over. The meteor or purple haze which I saw was indeed passed, but the light air that still blew was of heat to threaten suffocation. For my part, I found distinctly in my breast that I had imbibed a part of it, nor was I free of an asthmatic sensation till I had been some months in Italy, at the baths of Poretta, near two years afterwards." Though the severity of this blast seems to have passed over them almost instantaneously, it continued to blow so as to exhaust them till twenty minutes before five in the afternoon, lasting through all its stages very near six hours, and leaving them in a state of the utmost despondency.

SIMPLON, a village in Switzerland, in the canton of the Vallais, only to be noticed from giving its name to the most magnificent of the roads over the Alps. This road, which leads from Switzerland into Piedmont, was constructed by Bonaparte betwixt the years 1801 and 1806, and has been long considered as one of the noblest monuments of his genius and power. It is near seventy English miles in length, is in every part twenty-five feet in breadth, and with an ascent so gentle, only one inch and a half in six feet, that the heaviest carriage can pass down on both sides of the mountain without the necessity of applying the drag chain. It passes over several frightful precipices. It is carried through six solid rocks by means of arches called galleries, where by gunpowder a passage has been bored. Out of these the passenger steps into lovely valleys with the huts of the shepherds sprinkled on the sides, and looks through forests of pines, to behold the glaciers and the snow-toped mountains in lofty regions of the air. Some bold bridges lead over the deep fissures from one rock to another. The Italian side presents more picturesque scenery than the Swiss side, from the rocks being much more rugged. On that side, too, is the grand gallery, 690 feet in length, excavated through a granite rock, called, from a remarkable cascade near it, the gallery of Frissinone. The greatest height which the road attains, is at the gallery of the glaciers, where trees cease to grow, being somewhat more than 6000 feet above the level of the sea, while the mountain above it rises to the height of 11,000 feet. Owing to the expences of this magnificent road being to be provided for by the governments of Sardinia and of Switzerland, several repairs have been deferred or neglected, and it has in parts fallen into decay.

SIMPSON, Thomas, professor of mathematics at the Royal Academy at Woolwich, fellow of the Royal Society, and member of the Royal Academy at Stockholm, was born at Market Bosworth in Leicestershire in 1710. His father, a stuff-weaver, taught him only to read English, and brought him up to his own business; but meeting with a scientific pedlar, who likewise practised fortune-telling, young Simpson by his assistance and advice left off weaving, and professed astrology. As he improved in knowledge, however, he grew disgusted with this pretended art; and renouncing it, was driven to such difficulties for the subsistence of his family, that he came up to London, where he worked as a weaver, and taught mathematics at his spare hours. As his scholars increased, his abilities became better known, and he published his Treatise on Fluxions, by subscription, in 1737; in 1740, he published his Treatise on the Nature and Laws of Chance, and Essays in Speculative and Mixed Mathematics. After these, appeared his Doctrine of Annuities and Reversions; Mathematical Dissertations; Treatise on Algebra; Elements of Geometry; Trigonometry, Plane and Spherical; Select Exercises; and his Doctrine and Application of Fluxions, which he professes to be rather a new work, than a second edition of his former publication on Fluxions. In 1743, he obtained the mathematical professorship at Woolwich academy; and soon afterwards was chosen a member of the Royal Society, when the president and council, in consideration of his moderate circumstances, were pleased to excuse his admission-fees, and his giving bonds for the settled future payments. At the academy he exerted all his abilities in instructing the pupils who were the immediate objects of his duty, as well as others whom the superior officers of the ordnance permitted to be boarded and lodged in his house. In his manner of teaching he had a peculiar and happy address, a certain dignity and perspicuity, tempered with such a degree of mildness, as engaged the attention, esteem, and friendship of his scholars. He therefore acquired great applause from his superiors in the discharge of his duty. His application and close confinement, however, injured his health. Exercise and a proper regimen were prescribed to him, but to little purpose; for his spirits sunk gradually, till he became incapable of performing his duty, or even of reading the letters of his friends. The effects of this decay of nature were greatly increased by vexation of mind, owing to the haughty and insulting behaviour of his superior, the first professor of mathematics. This person, greatly his inferior in mathematical accomplishments, did what he could to make his situation uneasy, and even to depreciate him in the public opinion; but it was a vain endeavour, and only served to depress himself. At length his physicians advised his native air for his recovery, and he set out in February 1761; but was so fatigued by his journey, that upon his arrival at Bosworth, he betook himself to his chamber, and grew continually worse till the day of his death, which happened on the 14th of May, in the fifty-first year of his age.

Simpson's *Island*, in the south Pacific Ocean, discovered by Captain Carteret in 1767, four miles west from Carteret's Island. Long. 159. 20. E. Lat. 8. 26. S.

SIMSON, Dr. Robert, professor of mathematics in the university of Glasgow, was born in the year 1687, of a respectable family, which had held a small estate in the county of Lanark for some generations. He was, we think, the second son of the family. A younger brother was professor of medicine in the university of St. Andrews, and is known by some works of reputation, particularly a *Dissertation on the Nervous System*, occasioned by the dissection of a brain completely ossified.

Dr. Simson was educated in the university of Glasgow under the eye of some of his relations who were professors. Eager after knowledge, he made great progress in all his studies; and, as his mind did not, at the very first openings of science, strike into that path which afterwards so strongly attracted him, and in which he proceeded so far almost without a companion, he acquired in every walk of science a stock of information, which, though it had never been much augmented afterwards, would have done credit to a professional man in any of his studies. He became at a very early period, an adept in the philosophy and theology of the schools, was able to supply the place of a sick relation in the class of oriental languages, was noted for historical knowledge, and one of the most accomplished botanists of his time.

It was during his theological studies, as preparatory for his entering into orders, that mathematics took hold of his fancy. He used to tell in his convivial moments how he amused himself when preparing his exercises for the divinity hall. When tired with vague speculation, in which he did not meet with certainty to reward his labours, he turned up a book of oriental philology, in which he found something which he could discover to be true or to be false, without going out of the line of study which was to be of ultimate use to him. Sometimes even this could not relieve his fatigue. He then had recourse to mathematics, which never failed to satisfy and refresh him. For a long while he restricted himself to a very moderate use of the cordial, fearing that he would soon exhaust the small stock which so limited and abstract a science could yield; till at last he found, that the more he learned, a wider field opened to his view, and scenes that were inexhaustible. Becoming acquainted with subjects far beyond the elements of the science, and with numbers of names celebrated during that period of ardent research all over Europe, he found it to be a manly and important study, by which he was as likely to acquire reputation as by any other. About this time, too, a prospect began to open of making mathematics his profession for life. He then gave himself up to it without reserve.

His original incitement to this study as a treat, as something to please and refresh his mind in the midst of more severe tasks, gave a particular turn to his mathematical studies, from which he never could afterwards deviate. Perspicuity and elegance are more attainable, and more discernible, in pure geometry, than in any other parts of the science of measure. To this therefore he chiefly devoted himself. For the same reason he preferred the ancient mode of studying pure geometry, and even felt a dislike to the Cartesian method of substituting symbols for operations of the mind, and still more was he disgusted with the substitution of symbols for the very objects of discussion, for lines, surfaces, solids, and their affections. He was rather disposed, in the solution of an algebraical problem, where quantity alone was considered, to substitute figure and its affections for the algebraical symbols, and to convert the algebraic formula into an analogous geometrical theorem. And he came at last to consider algebraic analysis as little better than a kind of mechanical knack, in which we proceed without ideas of any kind, and obtain a result without meaning, and without being conscious of any process of reasoning, and therefore without any conviction of its truth. And there is no denying, that if genuine unsophisticated taste alone is to be consulted, Dr. Simson was in the right; for though it must also be acknowledged, that the reasoning in algebra is as strict as in the purest geometry of Euclid or Apollonius, the expert analyst has little perception of it as he goes on, and his final equation is not felt by himself as the result of ratiocination, any more than if he had obtained it by Pascal's arithmetical mill. This does not in the least diminish our admiration of the algebraic analysis; for its almost boundless grasp, its rapid and certain procedure, and the delicate metaphysics and great address which may be displayed in conducting it. Such, however, was the ground of the strong bias of Dr. Simson's mind to the analysis of the ancient geometers. It increased as he went forward; and his veneration for the ancient geometry was carried to a degree of idolatry. His chief labours were exerted in efforts to restore the works of the ancient geometers; and he has nowhere bestowed much pains in advancing the modern discoveries in mathematics. The noble inventions, for example, of fluxions and of logarithms, by which our progress in mathematical knowledge, and in the useful application of this knowledge, is so much promoted, attracted the notice of Dr. Simson; but he has contented himself with demonstrating their truth on the genuine principles of the ancient geometry. Yet was he thoroughly acquainted with all the modern discoveries; and there are to be seen amongst his papers, discussions and investigations in the Cartesian method, which show him thoroughly acquainted with all the principles, and even expert in the *tours de main*, of the most refined symbolical analysis.[1]

About the age of twenty-five, Dr. Simson was chosen professor of mathematics in the university of Glasgow. He went to London immediately after his appointment, and there formed an acquaintance with the most eminent men of that bright era of British science. Amongst these he always mentioned Captain Halley (the celebrated Dr. Edmund Halley) with particular respect; saying, that he had the most acute penetration, and the most just taste in that science, of any man he had ever known. And, indeed, Dr. Halley has strongly exemplified both of these in his divination of the work of Apollonius *de Sectione Spatii*, and the eighth book of his *Conics*, and in some of the most beautiful theorems in Sir Isaac Newton's *Principia*. Dr. Simson also admired the wide and masterly steps which Newton was accustomed to take in his investigations, and his manner of substituting geometrical figures for the quantities which are observed in the phenomena of nature. It was from Dr. Simson that the writer of this article had the remark which has been oftener than once repeated in the course of this work, "That the thirty-ninth proposition of the first book of the *Principia* was the most important proposition that had ever been exhibited to the physico-mathematical philosopher;" and he used always to illustrate to his more advanced scholars the superiority of the geometrical over the algebraic analysis, by comparing the solution given by Newton of the inverse problem of centripetal forces, in the forty-second proposition of that book, with the one given by John Bernoulli in the Memoirs of the Academy of Sciences at Paris for 1713. We have heard him say, that to his own knowledge Newton frequently investigated his propositions in the symbolical way, and that it was owing chiefly to Dr. Halley that they did not finally appear in that dress. But if Dr. Simson was well informed, we think it a great argument in favour of the symbolical analysis, when this most successful practical artist (for so we must call Newton when engaged in a task of discovery) found it conducive either to dispatch or perhaps to his very progress.

---

[1] In 1752 the writer of this article, being then his scholar, requested him to examine an account which he gave him of what he thought a new curve (a conchoid having a circle for its base.) Dr. Simson returned it next day with a regular list of its leading properties, and the investigation of such as he thought his scholar would not so easily trace. In this hasty scrawl the lines related to the circle were familiarly considered as arithmetical fractions of the radius considered only as unity. This was before Euler published his Arithmetic of the Sines and Tangents, now in universal use.

Returning to his academical chair, Dr. Simson discharged the duties of a professor for more than fifty years, with great honour to the university and to himself.

It is almost needless to say, that in his prelections he followed strictly the Euclidian method in elementary geometry. He made use of Theodosius as an introduction to spherical trigonometry. In the higher geometry, he prelected from his own Conics, and he gave a small specimen of the linear problems of the ancients, by explaining the properties, sometimes of the conchoid, sometimes of the cissoid, with their application to the solution of such problems. In the more advanced class, he was accustomed to give Napier's mode of conceiving logarithms, that is, quantities as generated by motion, and Mr. Coats's view of them, as the sums of ratiunculæ; and to demonstrate Newton's lemmas concerning the limits of ratios, and then to give the elements of the fluxionary calculus; and to finish his course with a select set of propositions in optics, gnomonics, and central forces. His method of teaching was simple and perspicuous, his elocution clear, and his manner easy and impressive. He had the respect, and still more the affection, of his scholars.

With respect to his studies, we have already informed the reader that they got an early bias to pure geometry, and to the elegant but scrupulous methods of the ancients. We have heard Dr. Simson say, that it was in a great measure owing to Dr. Halley that he so early directed his efforts to the restoration of the ancient geometers. He had recommended this to him, as the most certain way for him, then a very young man, both to acquire reputation, and to improve his own knowledge and taste; and he presented him with a copy of Pappus's *Mathematical Collections*, enriched with some of his own notes. The perspicuity of the ancient geometrical analysis, and a certain elegance in the nature of the solutions which it affords, especially by means of the local theorems, soon took firm hold of his fancy, and made him, with the sanguine expectation of a young man, direct his very first efforts to the recovery of this *in toto;* and the restoration of Euclid's *Porisms* was the first task to which he set himself. The accomplished geometer knows what a desperate task this was, from the scanty and mutilated account which we have of this work in a single passage of Pappus. It was an ambition which nothing but success could justify in so young an adventurer. He succeeded; and as early as 1718, seemed to have been in complete possession of this method of investigation, which was considered by the eminent geometers of antiquity as their surest guide through the labyrinths of the higher geometry. Dr. Simson gave a specimen of his discovery in 1723, in the *Philosophical Transactions;* and after this time he ceased not from his endeavours to recover that choice collection of Porisms which Euclid had collected, as of the most general use in the solution of difficult questions. What some of these must have been, was pointed out to Dr. Simson by the very nature of the general proposition of Pappus, which he has restored. Others were pointed out by the lemmas which Pappus has given as helps to the young mathematician towards their demonstration. And, being thus in possession of a considerable number, their mutual relations pointed out a sort of system, of which these made a part, and the blanks of which now remained to be filled up.

Dr. Simson, having thus gained his favourite point, had leisure to turn his attention to the other works of the ancient geometers; and the porisms of Euclid now had only an occasional share. The *loci plani* of Apollonius was another task which he very early engaged in, and completed about the year 1738. But, after it was printed, he imagined that he had not given the *ipsissimæ propositiones* of Apollonius, and in the precise spirit and order of that author. The impression lay by him for some years; and it was with great reluctance that he yielded to the entreaties of his mathematical friends, and published the work, in 1746, with some emendations, where he thought he had deviated farthest from his author. He quickly repented of this scanty concession, and recalled what he could of the small number of copies which he had given to the booksellers, and the impression again lay by him for years. He afterwards recorrected the work, and still with some reluctance allowed it to come abroad as the *Restitution of Apollonius.* The public, however, had not been so fastidious as Dr. Simson, and the work had acquired great celebrity, and he was now considered as one of the first and the most elegant geometers of the age; for, in the meantime, he had published his *Conic Sections*, a work of uncommon merit, whether we consider it as equivalent to a complete restitution of the celebrated work of Apollonius Pergæus, or as an excellent system of this important part of mathematics. It is marked with the same features as the *loci plani*, the most anxious solicitude to exhibit the very text of Apollonius, even in the propositions belonging to the books which had been completely lost. These could be recovered in no other way but by a thorough knowledge of the precise plan proposed by the author, and by taking it for granted that the author had accurately accomplished this plan. In this manner did Viviani proceed in the first attempt which was made to restore the conics of Apollonius; and he has given us a detail of the process of his conjectures, by which we may form an opinion of its justness, and of the probability how far he has attained the desired object. Dr. Simson's view in his performance was something different, deviating a little in this one case from his general track. He was not altogether pleased with the work of Viviani, even as augmented by the eighth book added by Halley, and his wish was to restore the ancient original. But, in the meantime, an academical text-book for conic sections was much wanted. He was much dissatisfied with those in common use; and he was not insensible of the advantage resulting from the considerations of these sections, independent of the cone first introduced by Dr. Wallis. He therefore composed this excellent treatise as an elementary book, not to supersede, but to prepare for the study of Apollonius; and accordingly he accommodates it to this purpose, and gives several important propositions in their proper places, expressly as restitutions of Apollonius, whom he keeps constantly in view through the whole work.

Much about this time, Dr. Simson seriously began to prepare a perfect edition of Euclid's *Elements*. The intimate acquaintance which he had by this time acquired with all the original works of the ancient geometers, and their ancient commentators and critics, encouraged him to hope that he could restore to its original lustre this leader in mathematical science; and the errors which had crept into this celebrated work, and which still remained in it, appeared ot magnitude sufficient to merit the most careful efforts for their removal. The *data* also, which were in like manner the introduction to the whole art of geometrical investigation, seemed to call more loudly for his amending hand. For it appears that the Saracens, who have preserved to us the writings of the ancients, have contented themselves with admiring these celebrated works, and have availed themselves of the knowledge which they contain; but they have shewn no inclination to add to the stock, or to promote the sciences which they had received. They could not do any thing without the synthetical books of the geometers; but, not meaning to go beyond the discoveries which they had made, they neglected all the books which related to the analytic art alone, and the greatest part of them (about twenty-five out of thirty) have irrecoverably perished. The data of Euclid have fortunately been preserved, but the book was neglected, and the only ancient copies, which are but three or four, are miserably erroneous and mutilated. Fortunately, it is no very arduous matter to reinstate this work in its original perfection. The plan is precise, both in its extent and its method. It has been restored, therefore, with success by more than one author. But Dr. Simson's comprehensive view of the whole analytical system pointed out to him many occasions for amendment. He therefore made its restitution a joint task with that of the elements. All the lovers of true geometry will acknowledge their obligations to him for the edition of the *Elements* and *Data* which he published about 1758. The text is corrected with the most judicious and scrupulous care, and the notes are inestimable, both for their information, and for the tendency which they must have to form the mind of the student to a true judgment and taste in mathematical subjects. The more accomplished reader will perhaps be sometimes disposed to smile at the axiom which seems to pervade the notes, "that a work of Euclid must be supposed without error or defect." If this was not the case, Euclid has been obliged to his editor in more instances than one. Nor should his greatest admirers think it impossible, that in the progress of human improvement, a geometrical truth should occur to one of these latter days, which escaped the notice of even the lynx-eyed Euclid. Such merit, however, Dr. Simson nowhere claims, but lays every blame of error, omission, or obscurity, to the charge of Proclus, Theon, and other editors and commentators of the renowned Grecian.

There is another work of Apollonius on which Dr. Simson has bestowed great pains, and has restored, as we imagine, *omnibus numeris perfectum*, namely, the *Sectio Determinata*; one of those performances which are of indispensable use in the application of the ancient analysis. This also seems to have been an early task, though we do not know the date of his labours on it. It did not appear till after his death, being then published along with the great work, the *Porisms* of Euclid, at the expense of the Earl Stanhope, a nobleman intimately conversant with the ancient geometry, and zealous for its reception amongst the mathematicians of the present age. He had kept up a constant correspondence with Dr. Simson on mathematical subjects; and at his death in 1768, engaged Mr. Clow, professor of logic in the university of Glasgow, to whose care the Doctor had left all his valuable papers, to make a selection of such as would serve to support and increase his well-earned reputation as the restorer of ancient geometry.

We have been thus particular in our account of Dr. Simson's labours in these works, because his manner of execution, whilst it does honour to his inventive powers, and shews his just taste in mathematical composition, also confirms our former assertion, that he carried his respect for the ancient geometers to a degree of superstitious idolatry, and that his fancy, unchecked, viewed them as incapable of error or imperfection. This is distinctly to be seen in the emendations which he has given of the texts, particularly in his editions of Euclid. Not only every imperfection of the reading is ascribed to the ignorance of copyists, and every indistinctness in the conception, inconclusiveness in the reasoning, and defect in the method, is ascribed to the ignorance or mistake of the commentators; but it is all along assumed that the work was perfect in its kind, and that by exhibiting a perfect work, we restore the genuine original. This is surely gratuitous; and it is very possible that it has, in some instances, made Dr. Simson fail of his anxious purpose, and give us even a better than the original. It has undoubtedly made him fail in what should have been his great purpose, namely, to give the world a connected system of the ancient geometrical analysis, such as would, in the first place, exhibit it in its most engaging form, elegant, perspicuous, and comprehensive; and, in the next place, such as should engage the mathematicians of the present age to adopt it as the most certain and successful conductor in those laborious and difficult researches in which the demands of modern science continually engage them. And this might have been expected, in the province of speculative geometry at least, from a person of such extensive knowledge of the properties of figure, and who had so eminently succeeded in the many trials which he had made of its powers. We might have expected that he would at least have exhibited in one systematic point of view, what the ancients had done in several detached branches of the science, and how far they had proceeded in the solution of the several successive classes of problems; and we might have hoped, that he would have instructed us in what manner we should apply that method to the solution of problems of a more elevated kind, daily presented to us in the questions of physico-mathematical science. By this he would have acquired distinguished honour, and science would have received the most valuable improvement. But Dr. Simson has done little of all this; and we cannot say that great helps have been derived from his labours by the eminent mathematicians of this age, who are successfully occupied in advancing our knowledge of nature, or in improving the arts of life. He has indeed contributed greatly to the entertainment of the speculative mathematician, who is more delighted with the conscious exercise of his own reasoning powers, than with the final result of his researches. Yet we are not even certain that Dr. Simson has done this to the extent he wished and hoped. He has not engaged the liking of mathematicians to this analysis, by presenting it in the most agreeable form. His own extreme anxiety to tread in the very footsteps of the original authors, has, in a thousand instances, precluded him from using his own extensive knowledge, that he might not employ principles which were not of a class inferior to that of the question in hand. Thus, of necessity, did the method appear trammelled. We are deterred from employing a process which appears to restrain us in the application of the knowledge which we have already acquired; and, disgusted with the tedious, and perhaps indirect path, by which we must arrive at an object which we see clearly over the hedge, and which we could reach by a few steps, of the security of which we are otherwise perfectly assured. These prepossessions are indeed founded on mistake; but the mistake is such, that all fall into it, till experience has enlarged their views. This circumstance alone has hitherto prevented mathematicians from acquiring that knowledge of the ancient analysis which would enable them to proceed in their researches with certainty, dispatch, and delight. It is therefore deeply to be regretted, that this eminent genius has occupied, in this superstitious palæology, a long and busy life, which might have been employed in original works of infinite advantage to the world, and honour to himself.

Our readers will, it is hoped, consider these observations as of general scientific importance, and as intimately connected with the history of mathematics; and therefore as not improperly introduced in the biographical account of one of the most eminent writers on this science. Dr. Simson claimed our notice as a mathematician; and his affectionate admiration of the ancient analysis is the prominent feature of his literary character. By this he is known all over Europe; and his name is never mentioned by any foreign author without some very honourable allusion to his distinguished geometrical elegance and skill. Dr. James Moor, professor of Greek in the University of Glasgow, no less eminent for his knowledge in ancient geometry than for his professional talents, put the following apposite inscription below a portrait of Dr. Simson: "Geometriam, sub Tyranno barbaro sæva servitute diu squalentem, in libertatem et decus antiquum vindicavit unus."

Yet it must not be understood that Dr. Simson's predilection for the geometrical analysis of the ancients did so far mislead him as to make him neglect the symbolical analysis of the present times; on the contrary, he was completely master of it, as has been already observed, and frequently employed it. In his academical lectures to the students of his upper classes, he used to point out its proper province, which he by no means limited by a scanty boundary, and in what cases it might be applied with safety and advantage even to questions of pure geometry. He once honoured the writer of this article with the sight of a very short dissertation on this subject, perhaps the one referred to in the preface to his *Conic Sections*. In this piece he was perhaps more liberal than the most zealous partizans of the symbolical analysis could desire, admitting as a sufficient equation of the Conic Sections $L=\frac{p^2\ c}{x^2}$, where L is the *latus rectum*, x is the distance of any point of the curve from the focus, p is the perpendicular drawn from the focus to the tangent in the given point, and c is the chord of the equicurve circle drawn through the focus. Unfortunately this dissertation was not found amongst his papers. He spoke in high terms of the analytical works of Cotes, and of the two Bernoullis. He was consulted by Mr. Maclaurin during the progress of his inestimable *Treatise of Fluxions*, and contributed not a little to the reputation of that work. The spirit of that most ingenious algebraic demonstration of the fluxions of a rectangle, and the very process of the argument, is the same with Dr. Simson's in his dissertation on the limits of quantities. It was therefore from a thorough acquaintance with the subject, and by a just taste, that he was induced to prefer his favourite analysis, or, to speak more properly, to exhort mathematicians to employ it in his own sphere, and not to become ignorant of geometry, while he successively employed the symbolical analysis in cases which did not require it, and which suffered by its admission. It must be acknowledged, however, that in his later years, the disgust which he felt at the artificial and slovenly employment on subjects of pure geometry, sometimes hindered him from even looking at the most refined and ingenious improvements of the algebraic analysis which occur in the writings ef Euler, D'Alembert, and other eminent masters. But, when properly informed of them, he never failed to give them their due praise; and we remember him speaking, in terms of great satisfaction, of an improvement of the infinitesmal calculus, by D'Alembert and D'Lagrange, in their researches concerning the propagation of sound, and the vibration of musical cords.

And that Dr. Simson was not only master of this calculus and the symbolical calculus in general, but held them in proper esteem, appears from two valuable dissertations to be found in his posthumous works; the one on logarithms, and the other on the limits of ratios. The last, in particular, shews how completely he was satisfied with respect to the solid foundation of the method of fluxions; and it contains an elegant and strict demonstration of all the applications which have been made of the method by its illustrious author to the objects of pure geometry.

We hoped to have given a much more complete and instructive account of this eminent geometer and his works, by the aid of a person fully acquainted with both, and able to appreciate their value; but an accident has deprived us of this assistance, when it was too late to procure an equivalent. And we must request our readers to accept of this very imperfect account, since we cannot do justice to Dr. Simson's merit unless almost equally conversant in all the geometry of the ancient Greeks.

The life of a literary man rarely teems with anecdote; and a mathematician, devoted to his studies, is perhaps more abstracted than any other person from the ordinary occurrences of life, and even the ordinary topics of conversation. Dr. Simson was of this class; and, having never married, lived entirely a college life. Having no occasion for the commodious house to which his place in the university entitled him, he contented himself with chambers, good, indeed, and spacious enough for his sober accommodation, and for receiving his choice collection of mathematical writers, but without any decoration or commodious furniture. His official servant sufficed for valet, footman, and chambermaid. As this retirement was entirely devoted to study, he entertained no company in his chambers, but in a neighbouring house, where his apartment was sacred to him and his guests.

Having in early life devoted himself to the restoration of the works of the ancient geometers, he studied them with unremitting attention; and, retiring from the promiscuous intercourse of the world, he contented himself with a small society of intimate friends, with whom he could lay aside every restraint of ceremony or reserve, and indulge in all the innocent frivolities of life. Every Friday evening was spent in a party at whist, in which he excelled, and took delight in instructing others, till increasing years made him less patient with the dulness of a scholar. The card-party was followed by an hour or two dedicated solely to playful conversation. In like manner, every Saturday he had a less select party to dinner at a house about a mile from town. The Doctor's long life gave him occasion to see the *dramatis personæ* of this little theatre completely changed, whilst he continued to give it a personal identity; so that, without any design or wish of his own, it became, as it were, his own house and his own family, and went by his name.

Dr. Simson was of a good stature, with a fine countenance; and even in his old age he had a graceful carriage and manner, and always, except when in mourning, dressed in light coloured clothes. He was of a cheerful disposition; and though he did not make the first advances to acquaintance, had the most affable manner, and strangers were at perfect ease in his company. He enjoyed a long course of uninterrupted health; but toward the close of life suffered from an acute disease, and was obliged to employ an assistant in his professional labours for a few years preceding his death, which happened in 1768, at the age of eighty-one. He left to the university his valuable library, which is now arranged apart from the rest of the books, and the public use of it is limited by particular rules. It is considered as the most choice collection of mathematical books and manuscripts in the kingdom, and many of them are rendered doubly valuable by Dr. Simson's notes. (B.B.B.)

SINAI, a celebrated mountain of Arabia, near the head of the Red sea, the place whence the divine law was given by Moses. It is surrounded by a vast and gloomy desert, the few inhabited spots of which are occupied by the Arabs, who live by plunder, and attack all passengers unless they form part of a large and well defended caravan. Mount Sinai belongs to the range of mountains called by the Arabs Zibbel Musa, and consists of several lofty summits, separated by frightful gulfs between precipitous rocks. At the foot of the mountain is the Greek convent of St. Catherine, founded in 1331. It is 120 feet in length and almost as many in breadth, built entirely of hewn stone. In this convent, the monks remain imprisoned by the wild Arabs of the surrounding country; and they are supplied with provisions by a basket drawn up by a cord and pulley to the height of thirty feet. The predatory bands of Arabs often fire upon the convent from the rocks adjacent, and make prisoners of the monks who venture beyond the walls, for whose restoration they exact a considerable ransom. The convent has an excellent garden at a little distance, which is reached by a subterraneous passage secured with iron gates. It has a temperate climate, owing to the elevation, and snow sometimes falls. Fruits, plants, and vegetables, are produced in the utmost profusion. The convent is eighty feet long and fifty-three broad, paved with marble and adorned with a variety of figures. It has many lamps of gold and silver, and the grand altar is gilded and adorned with jewels. The ascent of the mountain is steep, and is by steps cut in the rock, or loose stones piled in succession. A Christian church and a Turkish mosque crowns the summit of Mount Sinai; the former now greatly dilapidated. It commands a most extensive view over the Red Sea and the opposite coast of Thebais; beneath is the port of Tor, by which the commodities of India were formerly conveyed to Egypt. The descent is even more rugged and steep than the ascent; and terminates at the monastery of the Forty Saints, which has been plundered often by the Arabs. On the other side is the still loftier mountain of St. Catherine, 150 miles east of Suez.

SINCLAIR'S ROCKS, four small rocks off the south coast of New Holland, included by Capt. Hindens in Nuyt's archipelago.

SINDANGAN BAY, on the north-west coast of Mindanao, extending from north to south about 100 miles. Long. 123. 52. Lat. 8. 15. N.

SINDE, an extensive kingdom of Hindustan, which extends from the district of Shikarpoor on the frontier of Cabul, and the island of Bukkor in the Indus, along the level plain, watered by that river to the sea; in length about two hundred and fifty miles by eighty miles in average breadth. The general boundaries are the British principality of Cutch and the Indian ocean to the south; the kingdom of Jessulmere and the Rejistah, or Sandy Desert, to the east, which extends from the territories of Cutch five hundred and fifty miles in length by a hundred and fifty in breadth; the mountains of Belochistan on the west; and the provinces of Seewistan and Bahawulpoor on the north. It is a flat alluvial country, situated between the 23d and 27th degrees of north latitude, and the 67th and 71st degrees of east longitude; and is crossed in a diagonal direction by the Indus and its branches, which form a delta, in length about a hundred miles along the coast. The lower part of this delta is intersected by numerous rivers and creeks, like the delta of the Ganges, but it has no trees on it, the dry parts being covered with brush-wood, and the remainder, by much the greater part, being noisome swamps, or muddy lakes. The streams which break off from the Indus, diverge in all directions into other streams, which interlock into each other, and chequer the whole country. To trace in detail those complicated branches into which the main stream is thus divided would be useless. All those various streams which overspread the country, greatly increase its fertility; but often prove pernicious to those who dwell on the banks, by the exhalations which arise under a tropical sun, from the annual inundations. "Few countries," says Major Rennel, "are more unwholesome to European constitutions, particularly the lower part of the delta."

Sinde.

Sinde may be termed a level country, intersected with rocky hills. Those tracts which are within the limits of the inundation, rival in fertility the borders of the Nile. Even those parts which are at a distance from the river, are capable of being cultivated, provided there is no failure in the periodical rains. This, however, frequently happens, as no country in the world is more subject to drought. During great part of the south-west monsoon, or at least in the months of July, August, and part of September, which is the season of the periodical rains in most parts of India, the atmosphere is generally clouded, but no rain falls, except very near the sea. At Tatta, when it was visited by Captain Hamilton, no rain had fallen for three years. Owing to this, and to the vicinity of the sandy deserts, which bound this country on the east, and on the north-west, the heats are so violent, and the winds from these quarters so unwholesome, that the houses are contrived so as to be ventilated by means of apertures on the top of them, resembling the funnels of small chimneys. During the prevalence of the hot winds, the windows are shut in order to exclude the lower and hottest current of the air, along with the clouds of dust which it sets in motion; and the cooler portion descends into the house through the funnels.[1] When Lieutenant now Colonel Pottinger was at Tatta with the mission that was sent to the court of Hydrabad in 1808, the rains were extremely violent; they descended so heavily that the streets frequently ran like rivulets; and in the coolest apartment, the thermometer usually ranged from 94 to 102; this was in June. Towards the middle of July it became much cooler, and strong northerly gales set in, which cooled the air; and at Hydrabad, during the summer season, the mission experienced the heaviest falls of rain, which caused the Futelee river to overflow its banks; and owing to the exhalations from a burning sun, the thermometer seldom falling below 102, and the atmosphere at night being particularly oppressive, beyond, Colonel Pottinger observes, what he had ever experienced in India, the followers of the mission were attacked by fevers and other complaints; and it was only by taking regular exercise, and using requisite precautions, that the gentlemen of the mission continued to maintain themselves in health.[2]

The country increases in barrenness as it recedes eastward from the Indus, and its tributaries; and in the vicinity of the Northern Runn, it is described by Dr. Burnes, who travelled through this country in 1825, as a dead unproductive flat, a perfect desert, in which not a tree, house, nor human being, was to be seen, and where it was even difficult to procure a little brackish water from the stagnant marshes that were occasionally seen. For about fifty miles eastward from Cutch, as far as the town of Ruree, and nearly the same distance from the Indus, the country presents the same aspect; namely, a sterile flat. The town of Ruree, though superior to most of the towns in this country, yet being removed beyond the freshes of the Indus, had suffered severely from drought, so that the inhabitants were reduced below 500.[3] The villages which are met with in this country, have also the same miserable appearance, being far inferior to those of Cutch, on the eastern side of the Runn. In place of the stone buildings, and tiled roofs, which give an air of neatness and comfort to those of the latter country, they are for the most part collections of low huts, composed of clay and thatch; and even the mosques are built of the same frail materials, of rather greater elevation indeed, and with a feeble attempt at ornament. Many of the inhabitants inhabit grass hovels in the fields, from which, by hard labour, they extort a miserable subsistence. When either food or forage fail, it is not unusual for the whole population of a village to migrate to another station, as choice or necessity prompts them. Westward, the country gradually improves, and on approaching the region of the inundation, it presents an appearance of extensive cultivation, and the richness of the soil is everywhere remarkable. It is intersected by numerous canals from the branches of the Indus, dug for the purposes of navigation, and over which small brick bridges have been thrown, on which water wheels are placed, by which a supply of moisture is distributed over the fields. The country in the vicinity of Hydrabad assumes a hilly appearance; and westward of the Indus it is bounded by a pile of barren mountains, that are quite as inhospitable, both as to soil and climate, as the sandy desert which is seen at a distance from the Indus and its waters. Near the sea at Kurachee, in latitude 24. 52. north, longitude 67. 17. east, west of the river, the country is, for eight or ten miles, a dead flat; and as, when it was visited by Pottinger, there had been a want of rain for several seasons, the earth was quite burned, without the slightest trace of vegetation, except some small stunted bushes scattered over the plain. But the inhabitants assured him that in forty-eight hours after a plentiful fall of rain, the ground would be a perfect grass plat, moisture being here, as in other hot regions, the great agent of fertility.

Climate.

The climate is hot; the thermometer varying, in the months of June and July, from 90 to 100; and the country is within the range of the monsoons, and the periodical rains. It is mentioned, however, by Dr. Burnes, that in January 1828, the rain fell in torrents at Hydrabad, which was attended with more piercing cold than he had ever experienced in Europe. In the northern parts of Sinde the air is pure, and refreshed by the cooling breezes from the westward, so that the heat is far from being intolerable. On the western bank of the river, from the latitude of Sehwan in 26. 6., there is a variety of feature in the face of the country, some districts being mountainous, some flat, some intersected by ranges of low mountains down to the sea.[1]

The banks of the Indus near Hydrabad, and generally throughout its lower course, are well cultivated, except where the Ameers, the rulers of the country, have converted the most fruitful fields and districts into gloomy and impervious forests for the preservation of game; those princes being unfortunately passionately fond of hunting, and like all despotic princes, gratifying their inclinations at whatever expense of misery to their subjects. It is mentioned that one of the princes, Meer Futteh Ali, depopulated one of the most fertile spots in the neighbourhood of Hydrabad, which yielded two to three lacs of rupees annually, because frequented by a peculiar species of antelope, which he found great pleasure in hunting. And the youngest brother, Mourad Ali, banished the inhabitants of an ancient village and razed it to the ground, because the crowing of cocks, and the grazing of cattle, disturbed the game in the neighbouring lands, which were contiguous. The game laws of Europe are sufficiently tyrannical; but they are fortunately corrected by the milder influence of manners. During the swelling of the river, grain and other seeds are reared; the remainder of the year is employed in the production of indigo, sugar-cane, and all kinds of grain. They have also extensive pastures; and the country would rapidly advance in wealth, but for the oppressive rapacity of the government. It is the heavy taxes which ruin industry in this, as in most other eastern countries. Every beegah of land watered by a canal or wheel, pays a revenue of from $1\frac{1}{2}$ to $3\frac{1}{2}$ rupees to the government. A duty of one rupee is also charged on each kunwar, or 120 pounds of grain reaped by the farmers. Garden land producing fruit trees, pays $2\frac{1}{2}$ rupees per beegah; and the spring crop of tobacco is rated at $4\frac{1}{2}$ rupees per beegah. The tax on sugar is collected in kind, and is $4\frac{1}{2}$ rupees per beegah. But these are not the only exactions with which agriculture is burdened. Its produce has to pay other dues in the market before it is allowed to be sold. Boats that arrive at Tatta are all taxed in proportion to their value; and these exactions generally exceed the original cost of the articles on which they are imposed. The revenues that are derived from Kurachee, situated west of the Indus, at the south-western extremity of Sinde, of which it has become of late years the principal sea-port, are farmed, agreeable to the wretched policy that obtains throughout this country; and in 1809, according to the information of the able and enterprising traveller, Lieutenant Pottinger, there was paid on this account, into the public treasury, 99,000 rupees, or L.12,375; and the vender was supposed to clear 12,000 rupees. The revenues have since increased to one lack 23,000 rupees, equal to L.15,375. This increase of revenue is ascribed solely to the local advantages of the port, being a central point between India and the dominions of Cabul, as also Khorassan, Balk, Bokhara, &c. The disorderly state of the country, from the decreasing authority of the Khan of Kelat, diverted the trade into this route through Sinde, the merchants finding the heavy exactions imposed on them more tolerable than the risk of violence to which they were exposed in other parts.

It has been remarked that despotic power, wielded by wisdom and goodness, would constitute the best government. But unfortunately, in Sinde it is wielded neither by wisdom nor goodness, but is a fearful instrument of rapacity and oppression, in the hands of the tyrants who rule the country, who, having no conception that it is for their own interest that the people should thrive, despoil them of their wealth, thus crushing the seeds of future accumulation, and for ever preventing any improvement of the national revenues. Under this short-sighted policy, the imposts and taxation in Sinde, according to Dr. Burnes, whose work affords valuable information on this subject, are enormous, and paralyze the whole trade and industry of the country. With the characteristic recklessness of an arbitrary government, the revenues are farmed to the highest bidders, who, as they are responsible to their task-masters for the produce, and can never expect indulgence on any pretence, are obliged to satisfy their rapacity, and to extort a revenue by whatever means from the impoverished people. Were it not for the great natural advantages with which the country is blessed, in the never-failing supply of moisture from the inundation of the Indus, which renders the cultivator independent of the tropical rains, her industry must have sunk under the manifold evils of ignorance and misrule. This is a source of fertility, of which no tyranny can despoil this highly favoured land; and thus the bounty of Providence is here more effectual to renovate, than the wickedness of man to destroy. The cultivator looks with certainty to an abundant harvest, and is enabled to export of his abundance to other countries. "Hence," says the judicious traveller already referred to, "there is an appearance of plenty and contentment throughout this misgoverned land, which would surprise any traveller who did not take every circumstance into consideration." Certain checks, however imperfect, no doubt exist to the excesses of despotic power. The farmers of the revenues are generally Hindus, who have no influence with the Ameers, by whom they are despised for their religion, and envied on account of their wealth; and on this account, they are the more ready to listen to any complaints against their oppressions from the Ryots, and to grant them redress. This, however, is but a feeble safeguard against oppression; and it too often happens that the interests of the two parties lead them to unite in the spoliation of the helpless villager.

---

[1] Pottinger's Narrative of a Journey through Belochistan, chap. 9. p. 361.

The principal articles of domestic produce, which are exported chiefly from Kurachee, are rice, ghee, hides, shark fins, potash, saltpetre, assafœtida, bdellium, madder, frankincense, Tatta-cloths, indigo, oleaginous and other seeds. From Mooltan, and the countries to the northward, are imported for re-exportation, alum, musk, horses, Kashmeer shawls, dried fruit, diamonds, lapis lazuli, turquoise, and other precious stones and gums. Other imports are tin, iron, lead, steel, ivory, European manufactures, sandal and other scented woods, from the south of India; swords and carpets from Khorasan and Candahar, silk and other articles from the Persian Gulf. The merchants who are settled here from Mooltan are the principal traders, and the wealthiest part of the community. The exports from Sinde to Bombay consist of sharks' fins and flesh, bdellium, ghee, potash, saltpetre, hides, oil of sesame, wheat, assafœtida, oil, raisins, almonds, colouring plants, pistachio flowers and nuts, shawls, cloths, mustard, wild saffron, black cummin seed from Kerman, white cummin seed, chintzes both from Sinde and Khorasan. In return are received from Bombay, sugar, sugar-candy, steel, iron, tin, tutenaque, lead, cochineal, betel-nut, black pepper, dried cocoa nuts, vermillion, red lead, quicksilver, Bengal and China silks and cloths, cinnamon, cardamoms, cloves, nutmegs, sandal-wood, grapes, china ware, pearls, aloes, and amuttas. A considerable trade is carried on with Muscat, Cutch, and with Mooltan and Cabul. To Muscat the exports are dressed leather, rice, wheat, sirshif oil, ghee, bdellium, chintzes, and other cloths; for which the returns are dates, limes, roses, silk from the Persian province of Ghilan, elephants' teeth, pearls, almonds, preserved fruit, cowries, slaves, arsenic, senna from Mecca, quince seeds, and gum. From Cutch it derives a supply of cotton, snuff, unwrought iron found in Cutch, and the small Arabian aloe. The Indus affords an easy means of intercourse with this province and the countries to the northward, being navigable for small vessels to a great distance from the sea. With Mooltan and Cabul the trade is carried on chiefly by caravans, and also by merchants and travellers. It is proper to add, that the trade in the Indus had greatly decayed, and had become merely nominal, the ignorant and tyrannical policy of the Ameers having nearly crushed it in that province, and the unsettled state of the countries to the northward rendering it precarious in that quarter. In 1808 it was carried on by a few boats passing up and down with grain, saltpetre, salt, and firewood; though, with the increasing ascendancy of the British in this quarter, and the restoration of order and peace in these former regions of anarchy, the former intercourse has revived, and will now be carried on with greater security than ever. A factory, established at Tatta in 1756 by the East India Company, which carried on a considerable trade with the province of Sinde, and was withdrawn, probably from the demoralised state and poverty of the country; though so late as the beginning of the present century, Mr. Crow was a commercial resident at Tatta. An unsuccessful attempt was since made in 1808 to renew the intercourse; but the haughty and jealous chieftains who ruled in this province rejected all advances on the part of the British. Ever since the occupation of Cutch by the British troops in 1819, they viewed the extension of their dominions with distrust, and maintained a cold and unfriendly attitude. No European officer was allowed to cross the frontier from Cutch; and even a special envoy, who had proceeded from Bombay in 1820, on the invitation of their own minister, was coldly received, and it was only in 1825 that a most friendly letter was received, with an invitation to Dr. Burnes to proceed without delay to Hydrabad, on account of the alleged sickness of one of the principal chiefs. The invitation was accepted, and he was received with every mark of confidence. A treaty has been since ratified in 1838 by the Ameers of Sinde, providing for the reception of a British resident; to which office Colonel Pottinger has been appointed.

Government.

The government of Sinde is a military despotism. After a long era of civil commotion, Futteh Ali Khan was called to exercise the supreme power, who generously admitted his three brothers, Ghoolam Ali, Kurm Ali, and Mourad Ali, to a participation in his high destiny. He died in 1801, and Ghoolam Ali in 1811. The supreme power in Sinde is now vested in the two youngest and surviving brothers, Meers Kurm and Mourad Ali, who are known as the chief Ameers, and whose seals are affixed to all public documents issued in the name of the government. But there are others of the family who are scarcely inferior in rank to these princes, on whom has devolved the executive government. The two deceased brothers, Futteh and Ghoolam Ali, left sons, to whom they bequeathed their shares in the administration, and who, though they have been kept back by their youth, and the grasping spirit of their uncles, had, when Dr. Burnes was at Hydrabad in 1827, acquired ascendancy in the state; and since his departure, one of them had risen in successful rebellion, and had raised himself to a political equality with his relatives. The two sons of Mourad Ali, Noor Mahommed and Nusseer Khan, are also among the heads of the government. All these chiefs are in possession of respective portions of the revenues of Sinde. After the death of Futteh Ali, the province was partitioned into four shares, of which the largest belongs to Mourad Ali, who, on the plea of his having descendants, continued to despoil his brother and Meer Mahommed of much of their possessions. There are other nobles who are related to the royal family, and who are allowed to assume the title of meer, or lord, but are not permitted to interfere in the affairs of state, deriving their importance solely from their alliance with the reigning princes. The real power centres in Meer Mourad Ali, who is represented as a gloomy tyrant, a slave to avarice, and a plunderer of his people. At the court of the Ameers, every thing is conducted on a scale of magnificence scarcely equalled at any other court in Hindustan. The parade that was exhibited when Colonel Pottinger and Dr. Burnes were severally received at court, is described by these travellers; and they both agree in celebrating the surpassing richness and splendour of the scene. The princes, says the former writer, wore a vast number of jewels, beside those that were set in the hilts and scabbards of their swords and daggers; and their waist-belts displayed some extraordinary emeralds and rubies. They were seated on a thin felt, that extended all round the circle, and over which was laid a silk mattrass, about an inch thick, spread with a muslin cloth, embroidered in a most exquisite manner with gold and silver flowers. They reclined on three large pillows, covered with similar embroidery, which, with the display of jewels, gave the whole an inconceivably rich effect. "Many of the officers of government," he continues, "appeared in very good style; and the general splendour and richness of the scene far surpassed any thing we had expected to see at the court of Hydrabad."[1] The dress of the princes, which was not ornamental, consisted in fine muslin tunics, with costly sashes tied round their waists, and their turbans of thin transparent gauze were of the largest dimensions, about 2½ feet in diameter, and yet so neatly folded up, as to give them a very becoming appearance. Dr. Burnes observes, that when he was first introduced at court, the *coup d'œil* was splendid, and that the spectacle approached nearer than any thing he had seen to the fancies formed in childhood of eastern grandeur. The two principal Ameers were seated amid a group of elegantly attired figures, at the end of a lofty hall, spread with Persian carpetting, on their musnud, a slightly elevated cushion of French white satin, beautifully worked with flowers of silk and gold, the corners of which were raised by four massive and highly chased golden ornaments, resembling pine-apples, and, together with a long velvet pillow behind, covered with rich embroidery, presented a very grand appearance. There was no tinsel or gaudy display of scarlet; none of the incongruities seen at the Hindoo courts, of gorgeousness and dirt; but a simple and becoming elegance, far surpassing any thing he had seen in India. The Ameers and their attendants were habited nearly alike, in tunics of fine white muslin, neatly prepared and plaited, so as to resemble dimity, with sashes of silk and gold, wide Turkish trousers of silk tied at the ankle, chiefly dark blue, and Sindian caps made of gold brocade or embroidered velvet. "A pair of Cashmere shawls," adds Dr. Burnes, "of great beauty, generally white, thrown negligently over the arm, and a Persian dagger at the girdle, richly ornamented with diamonds or precious stones, completed the dress and decorations of each of the princes. All the officers in attendance, judging from their dress and manners, seemed to be of inferior rank. There was no crowding for places; the rabble had been shut entirely out of doors; and there was a degree of stillness and solemnity throughout the whole, and an order and decorum in the demeanour of each individual, which impressed one with a feeling of awe and respect. I could not have anticipated the brilliant collection of jewels and armour that is in possession of these princes, and is of all things calculated most to surprise a European stranger." Colonel Pottinger mentions with admiration the profusion of pearls which they displayed; the size of one which the prince carried in his hand, he declares was such as before he should have regarded as perfectly incredible; and a perfect emerald, suspended from the hilt of a dagger which one of the younger princes wore in his sash, was considerably larger than a pigeon's egg. They had still this emerald in their possession when Dr. Burnes visited the court; and the immense treasure which they have accumulated from the spoil of the country which they govern, consists in rubies, diamonds, pearls, and emeralds, with which their daggers, swords, and matchlocks are adorned, or they are worn as rings and clasps, on different parts of their dresses. Many of these precious stones were purchased at reduced prices from the unfortunate princes of the Cabul monarchy and the nobility, when they were reduced to ruin by the revolutions which took place in that kingdom; and merchants are encouraged to visit Sinde from all parts, in consequence of the avidity of the princes to buy up the precious articles in which they deal. One or two Persian goldsmiths are employed at court, who continue to display to the best advantage the jewellery of their masters; and the art of inlaying letters of gold on steel has been brought to the greatest perfection by these artizans. The Ameers of Sinde are also remarkably curious in the qualities of swords and gun-barrels; and they possess a more valuable collection of these articles than is to be met with in any other part of the world. The value of a sword is estimated by the age and fineness of the steel, or by the temper and watering. One which was shewn by Kurm Ali to Dr. Burnes, dated 1122, (A. D. 1708,) was valued at 2000 rupees, or about L.125. They have in their armoury swords that have been worn by almost every prince renowned in Asiatic story; by Shah Abbas the Great, Nadir Shah, Ahmed Shah Doranee, besides other equally illustrious personages. Their blades are generally embellished with inscriptions in gold, of verses from the Koran, or short prayers for aid and protection. They manage their swords with great skill; and though they are not heavier than common English sabres, Dr. Burnes mentions that he has seen one of them cut a large sheep, with one stroke, in two pieces, a feat that depends on a certain mode of striking that requires great practice and dexterity.

---

[1] Travels in Belochistan and in Sinde, chap. x. p. 367.

The Ameers are passionately fond of hunting; and for this purpose large tracts of fertile land are enclosed to prevent the egress of the quadrupeds, and are converted into jungle; and once or twice a-month they visit their different game preserves to enjoy the pleasures of the chace, though the manner of killing the game in this country does not bear the appellation. Their mode of hunting does not at all partake of the animation which belongs to that amusement in Europe. Their plan is to close up all the wells, except the one in front of their tents, to which, when the animals resort, being compelled by dire necessity, they are then shot by the Ameers, amid the acclamations of their followers. They never hunt on horseback; but sometimes, though rarely, go a deer shooting on camels, and none, except themselves, are permitted to fire at any game. There is rarely a sporting excursion which does not cost the lives of two or three of their subjects, a matter of extremely little consequence in this tyrannical country, either from their false aiming, or from the fury of the boars driven desperate. The mode in which those hunting excursions are conducted, marks the jealous policy of the tyrannical government. They are attended by large retinues; and they never previously announce in which direction they mean to travel; nor will any of the princes leave the other behind. They are afraid of leaving them this short interval for intrigue, and, perhaps, rebellion; and it was by being left for two or three hours behind, that one of the princes succeeded in his late rebellion. Though related, they place no confidence in each other. They sleep in apartments peculiarly contrived for safety, with loaded arms laid beside their uneasy pillows; though these precautions are now somewhat relaxed, in consequence of the long era of nearly forty years' tranquillity which the country has enjoyed under the existing regime. There is nothing like the spirit of independence among the courtiers or nobility of Sinde. They only retain their places by the most implicit obedience and the most fawning adulation to their superiors; and their habitual propensity to flatter a European who is in favour at court, or even each other, is ludicrous; scarcely two persons meet without indulging in the most fulsome strain of oriental flattery; social life is burdened with this ceremonious formality, which is the mark of inferior civilization, and is common in Persia, Cabul, and generally among the semi-barbarous tribes of Asia.

The whole family of the Ameers are extremely strict, and mere bigots in their intolerant religion. With one or two exceptions, they have become Sheahs, or followers of Ali; who hate the sect of the Soonees even more bitterly than Brahmins or Christians. They are remarkable for the intolerance with which they persecute the Hindus, forming a considerable proportion of their subjects, who are subjected to the most exasperating indignities, and often to the greatest cruelties; they are forced to adopt the Mahometan dress, and to allow their beards to grow. It is only lately that they have been allowed to ride on horseback, and it is only the few who are in the immediate service of government that are allowed the privilege and honour, as it is esteemed, of a saddle. Merchants of wealth and respectability may be seen mounted on asses and mules, considered unclean animals, such as none but the vilest outcasts in other Asiatic countries can touch with impunity; and they are obliged to descend and stand aside when any Musselman passes by. They are denied the free exercise of their religion; the tom-tom can only be beat when special permission is granted; and though images are placed in most of the temples at Hydrabad, the sound of music never echoes from their walls; they are subjected to other shocking and degrading cruelties revolting to humanity; any two of the true believers, by declaring that they have heard a Hindoo repeat a verse in the Koran, or the words "Mahomed the prophet," may procure his immediate circumcision, which this degraded and persecuted class consider the most cruel calamity that can befal them, in which, as it is resorted to on the slightest provocation, and performed with the deriding pretence that it is for their eternal happiness, the torture of the mind is added to that of the body. On the other hand, the most bigotted veneration is expressed for the Seynds, or descendants of the prophet. The meanest wretch who can boast a connection, however remote, with this holy stock, enjoys a station in society such as no temporal man can bestow. If any one, under whatever provocation, would dare to retaliate, by abusing or striking any one of this favoured class, he would be torn to pieces by the enraged populace; and, in consequence of this high favour which they enjoy, an idle herd of these wretches flock into Sinde from the neighbouring countries, where, besides being useless members of the community, and withal insolent and lazy, they debase the minds and drain the purses of the deluded inhabitants.

The Ameers commence business about two hours before day-break, each holding a levee to hear compliments, and to adjust the affairs belonging to his department. About sun-rise they repair to their apartments to dress, and appear shortly afterwards in durbar, where the whole family regularly assemble for transacting public business; all letters are then laid before them, which, being read and considered, and some time passed in conversation, they withdraw to their morning repast about ten or eleven o'clock. They again appear abroad about two o'clock and remain together until dark, when they repair for the night to their respective apartments. At the residences of the younger princes every thing forms a contrast to the stately ceremonial of the elder Ameers; all restraint is thrown aside, and every species of amusement, such as boar-baiting, fencing, ball practice, and wrestling, are pursued with avidity. At the public audiences in the durbar the Ameers, though courteous, are for the most part haughty and reserved in their manners; nothing approaching to familiarity being allowed between them and their most favoured servants. Under such a government as has been described, justice is very imperfectly administered. The Koran is the foundation of law as it is of religion; and between man and man disputes are generally settled fairly enough by the cadi, except where bribery is employed, when the best security for justice is a weighty purse. The Hindus generally settle all disputes among themselves by punchayets or juries, as is practised in many parts of Hindustan, as they have no encouragement to come before the ruling authorities. The native inhabitants, the Beloches, according to their military notions, generally take the law into their own hands, and act on the simple principle of retaliation; nor do the authorities interfere, except where the dispute extends to whole tribes, and seriously endangers the peace of the country. In this case they interfere to settle matters by force or by conciliation. A serious quarrel of this nature occurred when Dr. Burnes was at Hydrabad, when the contending parties were sent for by the princes, who, with much flattery and address, obtained a promise from them to desist.

Mili y force

The military force of Sinde is very inefficient; their armed retainers are few in number and contemptible in appearance. Several of the chiefs of the tribes reside at court, and they can collect in a few days their followers, who are generally employed in agriculture and other occupations. In this manner it is estimated that 40,000 men may be collected. But though the iron rod of oppression has repressed the daring spirit of the military classes, yet the anarchy which has prevailed in this, as in other parts of Hindustan, has nurtured, among the great body of the people, a spirit of disorder and a love of plunder which is ready to break out on all occasions. The country is, in short, filled with licentious banditti, and would have been, in the evil days that are passed, a fit nursery of recruits for the Pindarie bands. "Like hungry vultures," says Dr. Burnes, "they would almost seem to scent the battle from afar, for the train of dissension is no sooner lighted than war becomes their universal cry, and it is incredible in how short time they flock to the rendezvous." The late insurrection of the princes was settled in a few days; yet, in that short time, about 20,000 or 30,000 volunteers had joined the different standards, and they were hourly crowding in when the adjustment took place. In military qualities, the Sindian soldier ranks very low; he has no discipline nor steadiness in the field, though he is brave and hardy; and his vanity and gasconading are proverbial. The army presents, when assembled, a motley and ill-accoutred assemblage of mercenaries from all quarters, chiefly composed of ferocious adventurers from the mountains of Belochistan, to one of whose rude tribes the reigning house traces its origin. The Ameers are well aware of the inefficient state of their military force, and of the utter hopelessness of any conflict with the British arms. And this furnishes the explanation of their distance and reserve, justly fearing that any close intercourse would only expose the nakedness of the land. It is not easy to obtain any exact estimate of the revenue of Sinde. Colonel Pottinger states its total amount, including those of all the collateral branches of the reigning family, at sixty-one lacs of rupees yearly, equal to L.767,500 sterling, which shews an increase, since 1809, several years previous to his estimate, of L.232,750, the amount being, at that time, forty-two lacs and 78,000, or L.534,000 sterling.

The men of Sinde are dark in colour but are an exceedingly handsome race; above the medium height of Asiatics, with good features and well-formed limbs. The beauty of the women is proverbial, and it is remarked by Pottinger in his instructive and excellent work, that though he had only casual opportunities of seeing any of the higher class of females, yet among the dancing girls who came to exhibit before them, there was not one who was not distinguished by loveliness of face or the symmetry of her figure, and in most instances both these requisites of beauty were strikingly combined. The dress of the men consists of a loose shirt, a pair of trousers, puckered at the ancles, and a quilted cotton or cloth cap, ornamented with flowers of silk or gold sewed round the bottom: that of the women, with the exception of the cap, is much the same; they wear beside, underneath their shifts, a silk jacket made to fit the form, that laces behind; and when abroad, a cloth shirt wraps round the body, having one end brought round the crown of the head, and serving as a veil to cover the face from strangers. This traveller does not, however, commend, in the same degree, the character of the people, in which the bad qualities, according to his estimate, greatly predominate. They are, he observes, avaricious, full of deceit, cruel, ungrateful, and strangers to veracity; and all the extenuation which he offers for these vices is, that the present generation has grown up under a government whose extortion, ignorance, and tyranny, is unequalled in the world. The Sindians, however, he does not rate lower in the scale of morality than the population and society of the other nations of Asia. Their good qualities consist in personal bravery, abstinence, and obedience to their superiors; for which they are reckoned the best mercenary soldiers in Hindustan. In manners they are generally forward and unpolished; in intellect dark and inapt, and in hospitality and fidelity signally regardless and deficient.

History.

The ancient history of Sinde is involved in obscurity. When Alexander of Macedon invaded the country, it was

Sinde.

governed by Hindu Rajahs; and from that time little is known of its history till the rise and progress of the Mahomedan power. It was conquered by a general dispatched for this purpose by a lieutenant of the Ommade Caliph Walid in Sejestim and Candahar; and flourished under the vicegerents of the prophet till its conquest by the Sultan of Ghizni. It afterwards came under the jurisdiction of the Soomrai, a native tribe, and was again reduced by Mahommed Ghori, and annexed as a fief to the crown of Delhi, to which it remained attached for two centuries. In the various conquests and revolutions which subsequently took place in India, this country was the prize of the victor. It was finally subdued by the armies of Acbar about the year 1580, since which period its rulers have never ventured openly to avow their independence, though they have sometimes evaded the payment of the tribute fixed, and have even frequently appeared in arms against the lord paramount. Under the succeeding emperors the province of Sinde was kept under strict subjection, though the unsettled aspect of Hindustan sometimes encouraged the rulers of Sinde to withhold the tribute. In the mean time the introduction of vast tribes of Beloches as mercenaries, had changed the character of the population, and the rule of the family of Toor Khan had given place to the tribe of Caloras, sprung, it is supposed, from adventurers that followed the Persian army. The invasion of India by Nadir Shah in 1739, extended the rule of Persia over Sinde and all the provinces west of the Indus; but his assassination paved the way for the rise of the Dooranee empire under Ahmed Khan Seedozy, who declared himself king of Cabul, to whom Sinde after a time submitted, and has ever since been considered subordinate, though frequently rebelling and refusing to pay tribute. The country was long a scene of civil dissension, different competitors contending for the throne, the Talpoories, a tribe of Beloche origin, rebelling against the house of Calora. Their contentions were carried on with various success, and with ruin and misery to the country, which was wasted in these wars. Ahmed Shah, the conquerer of the Mahrattas in the battle of Panipart in 1761, exacted the tribute with all its arrears. In 1786, Meer Futteh Allee, the eldest of four brothers, was confirmed as ruler of the country. He admitted to a participation in his high destiny his three younger brothers, Ghoulam Ali, Kurm Ali, and Mourad Ali; and they agreed to reign together as the ameers or the lords of Sinde. Futteh Allee died in 1801, and Ghoulam Ali in 1811; and the country, as has been already mentioned, is now partitioned between the surviving brothers, and their respective sons.

It is scarcely possible that this outlying country of Sinde can remain long independent of British control. The late great and successful expedition, for the purpose of restoring Dost Mahommed to the throne of Cabul, however questionable its policy, has extended the power of the British in India into countries where their name was scarcely known before. All the intervening states through whose territories the army passed in its progress to the scene of action, viewed the mighty movement with a mixed feeling of jealousy and awe. Having seen the various states of India, its princes and chiefs, with their dependent tributaries, successively swallowed up in the wide extending sway of this European empire, they would willingly have joined in repelling its further advances into the interior of Asia; but they were overawed; and the late brilliant operations of the British will tend to confirm and extend their political influence, and will in the end bring all such petty states as Sinde, alternately the prey of despotism and anarchy, under the control or the direct supremacy of that great power, whose mighty empire in the east, reared up by a continued train of brilliant success for more than half a century, seems only a step in her farther progress to the dominion of Asia.

Sinde *River*, in Hindustan, has its rise in the high table land of the Malwah province to the west of Seronge; and after a winding course, falls into the Jumna six miles to the north of Calpee.

Sinde Sagor, a district of Hindustan in the province of Lahore, situated principally between the 31st and 32d degrees of north latitude. It is bounded on three sides by the Indus, the Ravey, and the Jhylum, and on the north by the mountains of Joud. Zinda Singh is the term by which the inhabitants of the districts under the Seiks bordering on the Indus are known; and the Nakai Singh is the name given to the Seiks who reside in the province of Mooltan.

SINDOORG, a town of Hindustan, in the territories of the Nagpoor Rajah, in the province of Gundwana, eleven miles S. by E. from Ruttanpoor. Long. 82. 40. E. Lat. 22. 7. N.

SINDKERA, a town of the Mahratta territories, in the province of Khandesh, 107 miles west from Boorhampoor. Long. 74. 40. E. Lat. 21. 11. N.

SINE, or *Right Sine of an Arch*, in *Trigonometry*, is a right line drawn from one end of that arch, perpendicular to the radius drawn to the other end of the arch; being always equal to half the cord of twice the arch.

SINGAN, a city of China of the first rank, in the frontier province of Shan-si. It formed at one time the imperial residence, and is still a very large and fine city. It is the rendezvous of the troops appointed to defend the empire on the north-western side. Long. 108. 29. E. Lat. 35. 14. N.

SINGAPORE. The island of Singapore is situated at the extremity of the peninsula, in the straits of Singapore, through which lies the route of vessels to and from the China seas. The town stands in lat. 1. 17. 22. N., long. 103. 51. 45. E., on a point of land near the western part of a bay, and is easily distinguished by a pleasant hill behind it, mostly cleared of trees, which abound on the island. This was the situation chosen by Sir Stamford Raffles for establishing a settlement under the protection of Britain, which might, in some degree, command the free navigation of the Straits of Malacca. He accordingly sailed from Calcutta for this purpose in the latter end of the year 1818, and in 1819 he hoisted the British flag, with a population of not more than 200 souls. In three months, according to the official letter of Sir Stamford Raffles, the number had increased to 3000; and at the date of the letter, April 1820, to 10,000, principally Chinese. Not less than 173 sail of vessels, of different descriptions, principally native, arrived and sailed in the course of the first two months, and in a short time it had grown up into an important commercial port. The rapid rise of this important station, is, perhaps, unequalled in the history of any other country, and marks the sagacity with which so central a situation was chosen, with respect to India and China, from the latter of which it is distant only five days' sail; in regard also to Java, the great islands of Borneo and Sumatra, and the Eastern Archipelago. Its natural advantages are great. It is placed on a rich soil, with fertile tracts of land in the neighbourhood, which give ample scope to agricultural improvement; and this, combined with the freedom from imposts, and the security for life and property, under a mild and enlightened government, are the circumstances which have attracted these industrious settlers, who, descrying from afar the ensign of freedom and justice, fly to it for protection from the tyranny and extortion of their own native rulers. The island of Singapore, which has been surveyed since the British settlement was established, is about twenty-seven miles in its greatest length, and fifteen in its greatest breadth. It is estimated to contain an area of 270 square miles; is diversified with hill and dale, and is adapted to the growth of numerous and valuable commodities. Plantations of gambier, pepper, and spices, have been already begun; cultivation has also extended to the neighbouring islands, which formerly afforded a harbour for pirates. The water that is found in the island is excellent; the soil is rich and fruitful; the temperature is comparatively cool, the thermometer ranging between 71 and 89; and the climate, on the whole, is salubrious. On the south side of the island, an inlet penetrates into the interior, which is about 300 feet wide towards its mouth, has regular tides, and is capable of admitting lighters for about a quarter of a mile from the sea. On this inlet the town is built. Between this and a parallel inlet, at the distance of a quarter of a mile, is a square plain, faced with a high sandy beach free from surf, and terminated on the inner side by a steep hill, of a sufficient elevation to possess a beautiful and commanding view of the surrounding country and the straits. On the frontier side of the inlet, is, on one hand, a regularly built Chinese town; and, on the other, beyond the rivulet, an extensive plain, in front of which the sandy beach stretches into an inner bay, and whence another inlet encompasses it behind. Singapore harbour, or rather roadstead, situated four miles to the N.N.E. of St. John's island in Singapore straits, affords a safe anchorage to ships in all seasons; and, being clear of sudden danger, the approach to it is rendered easy by day or by night. Its position is also favourable for connecting the navigation of the straits, the track which the ships pursue being distant about five miles. The ships are well sheltered at the anchorage from E.N.E. round to north and west, as far as S. by W.

The population of Singapore consists of Chinese, Malays, -Buggis. The principal merchants are Englishmen, of whom there are also a few shopkeepers, auctioneers, &c. Some of the respectable merchants are Chinese, as are also the cultivators and other labourers. The Malays are chiefly employed as fishermen, in cutting timber, and in bringing supplies into the town from the surrounding neighbourhood; and the boatmen are chiefly natives of the Coromandel coast.

Singapore trades to a great extent with all the countries and islands in the Eastern seas. One of the most valuable branches of trade is with Siam, which is carried on in the Siamese junks, which frequent the port of Singapore to the number of eighteen or twenty, and which are from 100 to 350 tons burden, the greater number being from 150 to 200. They import chiefly sugar, rice, cocoa nut oil, saffron wood, garro root, dried fish, and a small quantity of gamboge, sticklac, elephants' teeth, raw silk, and onions; and are said to be of the value of from 3000 to 15,000 Spanish dollars each. Many of these vessels belong entirely to their commanders, and the others to parties residing in Siam. Sugar is the most valuable part of their cargoes, which is nearly all taken by the European merchants, and is shipped for Europe, whither, also, are sent the elephants' teeth and gamboge. Of the numerous tribes who visit this settlement, the Siamese carry off the greatest quantity of manufactured goods. Their return cargoes consist of Bengal muslins, sannahs, and gurrahs, (pieces of dress,) chintzes, European long cloths, cambrics, long ells, camblets, woollens, bees' wax, camphor, gold dust, and a few rattans; cotton twist is now also sought after. This trade is entirely confined to the Chinese, who are chiefly natives of the country, descendants of Chinese settlers. The trade with Cochin-China is not nearly so extensive or valuable as that with Siam. It is also carried on by means of junks, verging from 100 to 200 tons burden, which come to the number annually of between thirty and forty, from various ports along the whole coast of that immense country, and the gulf of Tonquin. The imports consist chiefly of rice and salt; but they bring also in small quantities sticklac, gamboge, saffron wood, tortoise shell, coarse sugar, cocoa nut oil, cocoa nuts, pigs and goats, salted vegetables, and other provisions. The return cargoes consist chiefly of opium, also of European long cloths, long ells, cambrics, Madras cloths, Indian piece goods, woollens, camlets, and a small quantity of gambier and rattans. A considerable trade is carried on with Campar, an ancient Malayan state on the east coast of Sumatra. This trade is entirely in the hands of the Malays, there being no Chinese settlers in that country, and is carried on in small proas, which visit Singapore monthly, in small fleets of ten or twelve, well armed, to guard them against the attacks of pirates, who infest the numerous straits that are formed amongst the Asiatic islands. They carry from fifteen to thirty men, and are armed with two long brass guns, spears, swords, &c. Their cargoes consist principally of coffee; but they also bring gambier, bees' wax, twine, and cassia of an inferior quality, elephants' teeth, rhinoceros' horns, and a few rattans. These articles they readily dispose of on their arrival, to Chinese merchants, and receive in return white and unbleached Madras cloths, raw silk and cotton, European shirtings, cambrics, and chintzes, handkerchiefs, camblets, lead, iron, steel, gold thread, Java tobacco, sticklac, &c. Singapore also trades with the west coast of the island of Borneo, situated between Tanjong Dattoo and the northern extremity of the island, and with the Dutch settlements of Sambos, Mampawa and Pontianak. The whole of this trade is conducted by the Malays and Buggis, in proas belonging to the different ports whence they come. The proas from Borneo Proper are chiefly of the burden of from 800 to 1200 piculs, carrying from forty to sixty men each, and, like most native vessels, are well armed with long brass guns, as well as with spears, swords, and small arms. About fifteen or twenty of these vessels trade with Singapore; and they make generally two voyages in the course of a year. Their imports principally consist of pepper, camphor, bees' wax, birds' nests, tortoise shell, mother-of-pearl shells, and pearls; the cargoes being valued at from 2000 to 8000 Spanish dollars each. They are very readily disposed of to the richest Chinese merchants, in barter for blue and white Madras cloths, Bengal chintzes and white goods, European chintzes and long cloths, iron, steel, cotton twist in blue, red, and white, blue and yellow nankeens, Chinese gold thread, and various other minor articles. The annual value of this trade is estimated at from 60,000 to 70,000 Spanish dollars. With the Dutch settlements the trade is still more considerable. From Sambas about fifteen to twenty proas arrive at Singapore every six months, each bringing cargoes of gold dust, according to the means of the trader, and scarcely any other commodity, on account of the heavy duties imposed on exports to a British port. From Mampawa and Pontianak about thirty or forty proas come twice a-year with gold dust, diamonds, tin, and rattans. The different cargoes are said to vary from 2000 to 20,000 dollars; the value of the whole trade is estimated at 250,000 Spanish dollars. In return they take chiefly Bengal and Madras piece goods and iron. They take no British manufactured goods, in consequence of the heavy protecting duties imposed on them by the Dutch, for the encouragement of the trade of the mother country; and no opium, because it is monopolized by the government, of which, however, only a few chests are disposed of; the chief supply being brought by the contraband traders. About ten or twelve Chinese junks commonly arrive from Amoy and Canton. Their imports are earthenware, tiles, granite, slates, paper umbrellas, vermicelli, dried fruits, sticks, paper, tobacco, and a few nankeens, raw silk, &c. The cargoes from Canton are said generally to consist of the same articles, with the addition of silk, camlets, satins, camphor, sugar candy, and tea, and a much greater proportion of nankeens and raw silk. Those cargoes, of which the value of each is from 30,000 to 60,000 dollars, generally belong to the owners of the junks, who remain in China. These junks are generally of about from

350 to 400 tons burdens; they carry from eighty to a hundred seamen; and such is their ignorance of navigation, that great numbers, notwithstanding their being so fully manned, perish in the stormy seas that wash the Chinese shores. They bring annually about 2000 Chinese; and for several days after their arrival, the Sampan proas which trade to Rhio, Malacca, Penang, &c., are literally crowded with emigrants proceeding to the various neighbouring ports, with a view of getting employment in the pepper, coffee, and gambier plantations, and in the tin mines. Great numbers go to Java to the sugar and coffee plantations, and many to Borneo to collect gold dust. Those various imports, however, are not consumed in Singapore, which is rather a mercantile depôt of goods, from which they are dispersed all over the Eastern seas. The goods which are adapted for a European remittance, such as raw silk, nankeens, and camphor, are chiefly purchased by the Europeans from the Chinese merchants, through whose hands the trade chiefly passes. The other articles are taken by the proas which frequent the harbour, and are by these spread over the whole Archipelago. The exports of the Chinese from Singapore, are birds' nests, camphor, beche de-mer, sandal wood, ebony, tortoise shell, rattans, flint stones, buffaloes' hides, sharks' fins, tripang, European camlets, woollens, and long ells, and a few pieces of chintzes, long cloths, Bengal piece goods, tin, pepper, gambier, and from eight to ten chests of opium, a contraband article, the importation of which into Canton is now effectually proscribed. The exports of Singapore to Calcutta, Madras, and Bombay, amount in value to about 2,600,000, and the imports to 2,748,026 sicca rupees.

	Exports.	Imports.
1831–2..	7,825,786 dollars.	8,904,774 dollars.
1836–7...	7,806,965 „	8,243,629 „
1837–8...	8.024,123 „	8,881,195 „

No export or import duties are levied at this port, nor any anchorage, harbour, or lighthouse dues, or any fees; but a register is kept of all exports and imports. A newspaper is published once a-week, the *Singapore Chronicle.* The population of Singapore, as already stated, rapidly increased after the settlement was established. Population in 1823, 10,683. In 1828, the inhabitants, consisting of Europeans, Malays, Chinese, natives of Bengal, of Coromandel, Arabs, Buggis, and others, amounted to 17,664; in 1833, to 20,978. In 1838 a handsome new church was opened for worship. (*Asiatic Journal*, new series; *Singapore Chronicle;* Macculloch's *Commercial Dictionary.*)

SINGBOOM, a district and town in the province of Orissa. The province is situated between the 22d and 23d degrees of north latitude, and bounded on three sides by the districts of Chuta, Nagpoor, Michnapoor, and Mohurbunge; and on the south by that of Kunjeur. The town is possessed by Zemindars. Long. 85. 55. E. Lat. 22. 37. N.

SINGHEA, or SINGEE, a town of Hindustan, province of Bahar, situated on the river Gunduck. Long. 85. 15. E. Lat. 25. 52. N.

SINGHERICONDA, a town of the Northern Carnatic, twenty miles south from Ongole. Lat. 80. 2. E. Lat. 15. 14. N.

SINGING, in a general sense, means the production of appreciable and varied sounds by the voice. In a more limited sense, it means different inflexions of the voice through intervals admitted in music, and consistent with the rules of melodic modulation. It is well known that these inflexions differ from those of the voice in speaking. In singing, harshness of vocal *timbre*, (see MUSIC,) and falseness of intonation are much more frequently met with than the opposite qualities, especially among persons not trained to sing. Musical training, when applied to a person possessed of a naturally good quality of voice, and a good ear, produces effects that can hardly be imagined by those who have not watched them attentively. Upon the subject of vocal-training, the reader may consult any of the best treatises on singing. For some remarks on the mechanism of the human voice in singing, and the compasses of voices, see MUSIC.

SINGING of Birds. Birds may more correctly be said to *whistle* than to *sing*. This is shown by the structure of their vocal organs, as well as by the mechanism of the automaton singing-bird of Maillardet. The power of *singing* is confined to the human race. In the notes of but few birds can distinct melodic intervals be perceived. The notes of the quail, the cuckoo, &c. as well as many of the notes of the blackbird, &c. constitute distinct melodic intervals, and are therefore susceptible of musical notation. Captive singing-birds may be taught tunes, as in the case of piping-bullfinches, &c. These last have even been taught to perform in concert. We have observed, among a number of piping-bullfinches, marked differences of musical ear. Some piped well in tune; others more or less out of tune.

SINGROWLA, a district of Hindustan, in the province of Gundwana, situated about the 24th degree of north latitude, and bounded on the east by the district of Palamow in Bahar. The country is in general very desolate.

SINGUMNERE, a district of Hindustan, belonging to the Mahratta Peshwa, in the province of Aurungabad, situated about the 20th degree of north latitude. It is a hilly, but a fertile district. The chief towns are Singumnere, Battowal, and Bejapoor. The capital is of the same name. Long. 74. 40. E. Lat. 19. 46. N.

SINKEL, a town situated near the mouth of the Sinkel river, on the west coast of Sumatra. Long. 98. 26. E. Lat. 2. 15. N. Camphor, benzoin, wax, and gold, are exported from this place. Vessels that frequent this port are exposed to great danger from piratical attacks. The river Sinkel is the longest on the western coast, which rises in the mountains of Dalholi, and after a long course, empties itself into the sea by a mouth three quarters of a mile wide.

SINISTER, something on or towards the left hand. Hence some derive the word *sinister a sinendo*, because the gods, by such auguries, permit us to proceed in our designs.

SINISTER, is ordinarily used amongst us for unlucky; though, in the sacred rights of divination, the Romans used it in an opposite sense. Thus *avis sinistra*, or a bird on the left hand, was esteemed a happy omen; and hence in the law of the twelve tables, *Ava sinistra populi magister esto.*

SINISTER, in *Heraldry.* The sinister side of an escutcheon is the left-hand side; the sinister chief, the left angle of the chief; the sinister base, the left-hand part of the base.

SINISTER Aspect, amongst astrologers, is an appearance of two planets happening according to the succession of the signs, as Saturn in Aries, and Mars in the same degree of Gemini.

SINISTRI, a set of ancient heretics, so called because they held the left hand in abhorrence, and made it a point of religion not to receive any thing therewith.

SINKING FUND, a provision made by parliament, consisting of the surplusage of other funds, intended to be appropriated to the payment of the national debt; on the credit of which very large sums have been borrowed for public uses. See FUNDING SYSTEM.

SINOPLE, in *Heraldry*, denotes vert, or green colour in armories. Sinople is used to signify love, youth, beauty, rejoicing, and liberty; and hence it is that letters of grace, ambition, and legitimation, are always sealed with green wax.

SINTCHEI, one of the remote Kurile islands in the Eastern ocean. Long. 155. 14. E. Lat. 50. 15. N.

SINUOSITY, a series of bends and turns in arches or other irregular figures, sometimes jutting out and sometimes falling in.

SINUS, in *Anatomy*, denotes a cavity in certain bones and other parts, the entrance of which is very narrow, and the bottom wider and more spacious.

Sinus, in *Surgery*, a little cavity or sacculus, frequently formed by a wound or ulcer, in which pus is collected.

SION, a small town and port in the island of Bombay, situated about nine miles from the presidency, at the opposite extremity of the island, on the top of a small conical hill, where it commands the passage from Bombay to the neighbouring island of Salsette. A causeway was built by Mr. Duncan across a small arm of the sea, which separated the two islands. It has a draw-bridge in the centre.

SIPHANTO, an island in the Ægeian sea subject to Turkey, south-west from Paros, and north-east from Komili. It is forty-five square miles in extent, and generally mountainous. Its inhabitants are about 5000, chiefly Greek by religion, and wholly so by origin, who grow corn, capers, figs, oil, cotton, and vines. They have some small manufactures of silk, linen, sail-cloth, and straw hats. This island had in ancient times mines of gold and silver, but no traces of them now exist. There is one town and five villages. The town has the same name as the island. Lat. 37. 1. Long. 24. 33. E.

SI-PORAH, or Good Fortune Island, a woody island in the Eastern seas, inhabited by the same race of people as the Poggy or Napan islands, from which it lies north-west.

SIR, the title of a knight or baronet, which, for distinction's sake, as it is now given indiscriminately to all men, is always prefixed to the knight's Christian name, either in speaking or in writing to him.

Sir Charles Hardy's island, in the Southern Pacific Ocean, discovered by Captain Carteret in the year 1767. Long. 154. 6. E. Lat. 4. 38. S.

Sir Charles Hardy's Islands, a cluster of small islands in the South Pacific Ocean, discovered by Captain Cook in 1770. Long. 217. W. Lat. 11. 55. S.

Sir Charles Saunders' Island, or *Tapooamanhoo*, in the Southern Pacific Ocean, discovered by Captain Wallis in 1765. It is about six miles in length. Long. 150. 40. W. Lat. 17. 28. S.

Sir Henry Martin's Island, in the Pacific Ocean, discovered by Lieutenant Hergest in 1792, and the most fertile and considerable of the group to which it belongs. Long. 220. 19. E. Lat. 80. 51. S.

Sir Isaac Point, a cape on the south coast of New Holland. Long. 135. 10. E. Lat. 34. 27. S.

Sir Joseph Banks' Group, a cluster of small islands in Spencer's Gulf, on the south coast of New Holland.

Sir Roger Curtis' Isles, an island, with two smaller ones near it, on the south coast of New Holland, twenty-two miles south-east of Wilson's promontory.

SIRAF, a small sea-port of Persia, in Laristan, chiefly inhabited by Arabians. Thirty-eight miles south-west of Lar.

SIRCAR, or Circar, any office under the government in Hindustan. It is sometimes used for the state of government itself; likewise a province, or any number of pergunnahs placed under one head in the government books, for convenience in keeping accounts. In common usage, the under banyans of European gentlemen are, in Bengal, called *sircars*.

SIRE, a title of honour formerly given to the king of France as a mark of sovereignty.

Sire, was also anciently used in the same sense with *sieur* and *seigneur*, and applied to barons, gentlemen, and citizens.

SIRENS, in fabulous history, certain celebrated songstresses who were ranked amongst the demigods of antiquity. Hyginus places their birth amongst the consequences of the rape of Prosperine. Others make them daughters of the river Acheleüs and one of the muses. The number of the Sirens was three, and their names were Parthenope, Lygea, and Leucosia. Some make them half women and half fish; others half women and half birds; there are antique representations of them still subsisting under both these forms. Pausanias tells us, that the Sirens, by the persuasion of Juno, challenged the Muses to a trial of skill in singing; and these having vanquished them, plucked the golden feathers from the wings of the Sirens, and formed them into crowns, with which they adorned their own heads. The Argonauts are said to have been diverted from the enchantment of their songs by the superior strains of Orpheus, Ulysses, however, had great difficulty in securing himself from seduction.

Pope, in his notes to the twelfth book of the Odyssey, observes, that the critics have greatly laboured to explain what was the foundation of this fiction of the Sirens. We are told by some, that the Sirens were queens of certain small islands named *Sirenusæ*, that lie near Capræa in Italy, and chiefly inhabited the promontory of Minerva, upon the top of which that goddess had a temple built by Ulysses.

Mr. Bryant says, however, that the Sirens were Cuthite and Canaanitish priests, who had founded temples in Sicily, which were rendered infamous on account of the women who officiated. They were much addicted to cruel rites, so that the shores upon which they resided are described as covered with the bones of men destroyed by their artifice.

All ancient authors agree in telling us, that Sirens inhabited the coast of Sicily. The name, according to Bochart, who derives it from the Phœnician language, implies a songstress. Hence it is probable, says Dr. Burney, that in ancient times there may have been excellent singers, but of corrupt morals, on the coast of Sicily, who, by seducing voyagers, gave rise to this fable. And if this conjecture be well founded, he observes, the Muses are not the only pagan divinities who preserved their influence over mankind in modern times; for every age has its Sirens, and every Siren her votaries. When beauty and talents, both powerful in themselves, are united, they become still more attractive.

SIRGOOJAH, a town and district of Hindustan, in the province of Gundwana, the latter situated about the 23d degree of north latitude. The town is situated about twelve miles from the northern frontier of Palamow. Long. 83. 50. E. Lat. 23. 5. N.

SIRHIND, a town and district in the province of Delhi, of which the latter occupies the north-western quarter, being situated between the 30th and 31st degrees of north latitude. It is not fertile, being barren and sandy, and in many places destitute of water. Its vicinity to the capital was, however, in its favour, as the Afghan emperor, Feroze III. caused several canals to be cut from the rivers Jumna and Suttubje, in order to fertilize it. The country is at present possessed by the Seiks. Its principal towns are Paticola, which is large and flourishing, and Tahnesir. The town was built or repaired by Sultan Feroze about the year 1351. It is now a scene of desolation, and has never recovered the dreadful ravages to which it was exposed by the Seiks in 1707. It is 155 miles north north-west from Delhi. Long. 75. 55. E. Lat. 30. 40. N.

SIRINAGAR, a town of Hindustan, in the province of Allahabad, district of Bundelama, twelve miles north north-east from Chatterpoor. Long. 79. 55. E. Lat. 25. 6. N.

SIROCCO, a periodical wind which generally blows in Italy and Dalmatia every year about Easter. It blows from the south-east by south. It is attended with heat, but not rain. Its ordinary period is twenty days, and it usually ceases at sunset.

SIRSEY, a small town of Hindustan, in the province of Bahar, twenty-five miles east south-east from Patna. Long. 85. 35. E. Long. 25. 22. N.

SIRVATON, a rock in the Eastern seas, near the north coast of Java. Long. 110. 49. E. Lat. 6. 36. S.

SISTRUM, or Cistrum, a kind of ancient musical instrument used by the priests of Isis and Osiris. It is described by Spon as of an oval form; in manner of a racket, with three sticks traversing it breadthwise, which playing freely by the agitation of the whole instrument, yielded a kind of sound which to them seemed melodious. Mr. Malcom takes the sistrum to be no better than a kind of rattle. Oiselius observes, that the sistrum is found represented on several medals, and on talismans.

Sistrum, or *Cistrum*, an ancient Egyptian musical instrument of percussion. A similar instrument, consisting of moveable metal rods passing through holes in a metal plate, is used in modern military bands.

SISTERS, two small islands in the great southern ocean, lying in the strait between Van Dieman's Land and the south-west coast of New Holland.

SISTERON, an arrondisement of the department of the Lower Alps in France, 341⅓ square miles in extent. It is divided into five cantons, which are subdivided into fifty communes, containing in 1836, 26,643 inhabitants. The capital is the city of the same name. It stands on the river Durance, where the Baech falls into that stream, at the foot of a rock on which is an ancient castle commanding a fine prospect. It is well built, and has a cathedral with a fine altar-piece. In 1836, it contained about 4546 inhabitants, who deal largely in wool, and cultivate almonds very extensively. Lat. 44. 11. 51. Long. 5. 51. 13. E.

SISYPHUS, in fabulous history, one of the descendants of Eolus, married Merope, one of the Pleiades, who bore him Glaucus. He resided at Epyra in Peloponnesus, and was a very crafty man. Others say, that he was a Trojan secretary, who was punished for discovering secrets of state; and others, that he was a notorious robber, who was killed by Theseus. All the poets, however, agree that he was punished in Tartarus for his crimes, by rolling a great stone to the top of a hill, which constantly recoiled, and rolling down incessantly, renewed his labour.

SITANG, a large river of the Birman empire, province of Pegu, which rises in a range of mountains about the 20th degree of north latitude, and passing the ancient city of Pegu, falls into the gulf of Murtaban.

SITAR, an Indian musical instrument resembling the European guitar. Some writers maintain that the guitar, the lute, the violin, &c., are all of oriental origin. The Indian *saringee* is similar to the European violin.

SITOPHYLAX, Σιτοφυλαξ, formed from σιτος, corn, and φυλαξ, keeper in antiquity, an Athenian magistrate, who had the superintendence of the corn, and was to take care that nobody bought more than was necessary for the provision of his family. By the Attic laws, particular persons were prohibited from buying more than fifty measures of wheat a man; and that such persons might not purchase more, the sitophylax was appointed to see the laws properly executed. It was a capital crime to prevaricate in it. There were fifteen of these *sitopylaces*, ten for the city, and five for the Piræus.

SITTINGBOURNE, a town in the hundred of Milton, in the lathe of Scray, in the county of Kent, forty miles from London. It depends chiefly on the trade arising from its being on the great road from London to Dover. The inhabitants were in 1801, 1347; in 1811, 1362; in 1821, 1537; and in 1831, 2182.

SITTIVACCA, a small town in the island of Ceylon. It is separated from the king of Candy's country by a large branch of the Malivaddy river. Long. 80. 13. E. Lat. 7. 2. N.

SITUS, in *Algebra* and *Geometry*, denotes the situation of lines, surfaces, and the like. Worfius delivers some things in geometry, which are not deduced from common analysis, particularly matters depending on the *situs* of lines and figures. Leibnitz has even founded a particular kind of analysis upon it, called *calculus situs*.

SIUT, or Siout, a large town of Upper Egypt, situated on the western bank of the Nile, about half a mile from the river, with which it communicates by a canal, crossed by a bridge of three arches. The inhabitants are chiefly Copts, who are extensively employed in the manufacture of blue cloth, with which they carry on a considerable trade, and likewise in earthenware, natoon, and opium. The surrounding country is very fertile, producing abundance of fruits; great quantities of wheat, barley, dhourra, and hemp, are likewise raised. Siut is the rendezvous of the caravans which proceed from Egypt southwards into the interior of Africa, to Sennaar and Darfur, from which countries they bring slaves and gold. This town is supposed to be the ancient Lycopolis; but the only remarkable antiquity which it presents, consists in the excavations made in the neighbouring mountains. These are numerous, consisting of chambers, many of which are thirty feet in height, covered with hieroglyphics, and exhibiting symbolical figures. They were most probably formed for sepulchral purposes. The town is large and populous, and the extensive district attached is likewise thickly inhabited. The united population amounts to 200,000. The taxes are reckoned at L.40,000. Lat. 27. 13. 14. N. Long. 31. 13. 32. E.

SIVA, a name given by the Hindus to the Supreme Being, when considered as the avenger or destroyer. Sir William Jones has shown that in several respects the character of Jupiter and Siva are the same. As Jupiter overthrew the Titans and giants, so did Siva overthrow the Daityas, or children of Ditti, who frequently rebelled against heaven; and as during the contest the god of Olympus was furnished with lightning and thunderbolts by an eagle, so Brahma, who is sometimes represented riding on the Garuda, or eagle, presented the god of destruction with fiery shafts. Siva also corresponds with the Stygian Jove, or Pluto; for, if we can rely on the Persian translation of the Bhágavat, the sovereign of Pátála, or the infernal regions, is the king of serpents, named Seshanaga, who is exhibited in painting and sculpture, with a diadem and sceptre, in the same manner as Pluto. There is yet another attribute of Siva, or Mahádéva, by which he is visibly distinguished in the drawings and temples of Bengal. To destroy, according to the Vedantis of India, the Sufis of Persia, and many philosophers of our European schools, is only to generate and reproduce in another form. Hence the god of destruction is holden in this country to preside over generation, as a symbol of which he rides on a white bull. Can we doubt that the loves and feats of Jupiter Genitor, not forgetting the white bull of Europa, and his extraordinary title of Lapis, for which no satisfactory reason is commonly given, have a connection with the Indian philosophy and mythology?

SIVANA Samudra, an island formed by the river Caveny, in the province of north Coimbetoor, about nine miles in length, by one in breadth. It is remarkable for an uncommon grand cataract near it; and it communicates with the continent by a bridge formerly magnificent, and three hundred yards in length, but is now in ruins.

SIWAH, a considerable oasis of the Lybian desert, on the route from Egypt to Fezzan, and the most interesting island of the waste, as being the supposed site of the temple of Jupiter Ammon. It is situated in latitude 29° 12′ north, and longitude 26° 5′ east. Horneman represents it as fifty miles in circumference; but subsequent travellers have reduced its dimensions to about one half of that. The nearest distance from the river does not exceed 120 miles. Date trees cover a large portion of the soil, which is extremely fertile; but the palm, pomegranate, olive, vine, fig, apricot, plum, and even apple, flourish in the gardens. Tepid saline springs are numerous throughout the district; and shocks of earthquakes are here frequently felt. The town of Siwah is built upon a steep conical rock, and both in external aspect and internal arrangement, presents a striking and singular appearance. The streets are narrow, crooked, and so dark, that artificial light is required at noon-day. Each house has several floors, the upper communicating with the lower by galleries and chambers which cover the streets. The houses and walls are for the most part built of natron or mineral soda, and rock salt mixed with sand, coated with a gypseous earth, which preserves the salt from melting. The total population of the town is from 2000 to 2500; that of the whole oasis is supposed to amount to 8000 souls.

The great object of interest connected with this place, is, as we have said, the ruins of what is conjectured to have been the famous temple of Ammon. They are situated a league and a half east of the town, and are called by the natives Om Beydeh. The edifice has been built in the Egyptian style of architecture. The vestiges of a triple enclosure, enormous stones lying on the ground, and masses still standing, prove it to have been a monument of the first order. The part which is in tolerable preservation is thirty feet in length, and consists of part of a gateway and two great walls, which are covered with three immense stones, measuring thirty-four feet by twenty-seven. The only apartment which has been distinctly made out is 112 feet in length; the whole area of ruins being a rectangular space about 360 feet by 300. The decorations are observed to bear the closest resemblance to those of the Egyptian monuments; the figures, scenes, and arrangements being entirely the same. Here are seen the identical style, cast of countenance, costumes and sacrifices, as in the monuments of Thebaid. Here is the god with the ram's head, priests in long procession, multitudes of hieroglyphic tables, and at the entrance is sculptured in full relief the figure of Typhon, or the evil genius, about five feet in height. Nearly a mile from these ruins is situated the fountain of the sun, dedicated of old to the Ammonian deity. It is a small marsh rather than a well, extending about ninety feet in length by sixty in breadth, but is at the same time perfectly transparent. The diurnal change of temperature recorded by the father of history is quite perceptible. A temple stands near this spring, and there are other temples and lakes extending in succession towards the west. Major Rennel has employed much learning to prove that Siwah is the site of the famous temple of Ammon, and with considerable success. See his work, *The Geographical System of Herodotus Examined and Explained*, &c. vol. ii. p. 230.

SIX ISLANDS, small islands in the eastern seas, near the north coast of Java. Long. 110. 49. E. Lat. 6. 36. S.

SIXTH, *in Music.* (See INTERVAL and MUSIC.)

SIXTUS V., POPE, was born on the 13th of December 1521, in La Marca, a village in the seigniory of Montalto. His father, Francis Peretti, was a gardener, and his mother a servant maid. He was their eldest child, and was called Felix. At the age of nine he was hired out to an inhabitant of the village to keep sheep; but disobliging his master, he was soon afterwards degraded to be keeper of the hogs. He was engaged in this employment when father Michael Angelo Selleri, a Franciscan friar, asked the road to Ascoli, where he was going to preach. Young Felix conducted him thither, and struck the father so much with his conversation and eagerness for knowledge, that he recommended him to the fraternity to which he had come. Accordingly he was received amongst them, invested with the habit of a lay brother, and placed under the sacristan, to assist in sweeping the church, lighting the candles, and other offices of that nature, for which he was to be taught the responses, and the rudiments of grammar. His progress in learning was so surprising, that at the age of fourteen he was thought qualified to begin his noviciate, and was admitted the year following to make his profession.

He pursued his studies with such unwearied assiduity, that he was soon reckoned equal to the best disputants. He was ordained priest in 1545, when he assumed the name of father Montalto; soon afterwards he took his doctor's degree, and was appointed professor of theology at Sienna. It was then that he so effectually recommended himself to Cardinal Carpi, and his secretary Bossius, that they ever remained his steady friends. Meanwhile the severity and obstinacy of his temper incessantly engaged him in disputes with his monastic brethren. His reputation for eloquence, which was now spread about this time over Italy, gained him some new friends. Amongst these were the Colonna family, and father Ghisilieri, by whose recommendation he was appointed inquisitor-general at Venice; but he exercised that office with so much severity, that he was obliged to flee precipitately from that city. Upon this he went to Rome, where he was made procurator-general of his order, and soon afterwards accompanied Cardinal Buon Compagnon into Spain, as a chaplain and consultor to the inquisition. There he was treated with great respect, and liberal offers were made to induce him to continue in Spain, which, however, he could not be prevailed on to accept.

In the meantime news were brought to Madrid that Pius IV. was dead, and that father Ghisilieri, who had been made Cardinal Alexandrino by Paul IV. had succeeded him under the name of Pius V. These tidings filled Montalto with joy, and not without reason, for he was immediately invested by the pontiff with new dignities. He was made general of his order, bishop of St. Agatha, soon afterwards raised to the dignity of cardinal, and received a pension. About this time he was employed by the pope to draw up the bill of excommunication against queen Elizabeth.

He began now to cast his eyes upon the papacy; and, in order to obtain it, formed and executed a plan of hypocrisy with unparalleled constancy and success. He became humble, patient, and affable. He changed his dress, his air, his words, and his actions, so completely, that his most intimate friends declared him a new man. Never was there such an absolute victory gained over the passions; never was a fictitious character so long maintained, nor the foibles of human nature so artfully concealed. He courted the ambassadors of every foreign power, but attached himself to the interests of none; nor did he accept a single favour that would have laid him under any peculiar obligation. He had formerly treated his relations with the greatest tenderness, but he now changed his behaviour altogether. When his brother Anthony came to visit him, he lodged him in an inn, and sent him home next day, charging him to inform his family that he was now dead to his relations and the world.

When Pius V. died in 1572, he entered the conclave with the other cardinals, but seemed altogether indifferent about the election, and never left his apartments except to his devotion. When solicited to join any party, he declined it, declaring that he was of no consequence, and that he would leave the choice of a pope entirely to persons of greater knowledge and experience. When Cardinal Buon Compagnon, who assumed the name of Gregory XIII. was elected, Montalto assured him that he never wished for any thing so much in his life, and that he would always remember his goodness, and the favours he had conferred on him in Spain. But the new pope treated him with the greatest contempt, and deprived him of his pension. The cardinals also, deceived by his artifices, paid him no greater respect, and used to call him, by way of ridicule, the Roman beast, the ass of La Marca.

He now assumed all the infirmities of old age; his head hung down upon his shoulders; he tottered as he walked, and supported himself on a staff. His voice became feeble, and was often interrupted by a cough so exceedingly severe, that it seemed every moment to threaten his dissolution. He interfered in no public transactions, but spent his whole time in acts of devotion and benevolence. Mean time he constantly employed the ablest spies, who brought him intelligence of every particular.

When Gregory XIII. died in 1585, he entered the con-

Sixtus V.

clave with the greatest reluctance, and immediately shut himself up in his chamber, and was no more thought of than if he had not existed. When he went to mass, for which purpose alone he left his apartment, he appeared perfectly indifferent about the event of the election. He joined no party, yet flattered all.

He knew early that there would be great divisions in the conclave, and he was aware that when the leaders of the different parties were disappointed in their own views, they all frequently agreed in the election of some old and infirm cardinal, the length of whose life would merely enable them to prepare themselves sufficiently for the next vacancy. These views directed his conduct, nor was he mistaken in his hopes of success.

Three cardinals, the leaders of opposite factions, being unable to procure the election which each of them wished, unanimously agreed to make choice of Montalto. When they came to acquaint him with their intention, he fell into such a violent fit of coughing, that every person thought he would expire on the spot. He told them that his reign would last but a few days; that, besides a continual difficulty in breathing, he wanted strength to support such a weight, and that his small experience rendered him very unfit for so important a charge. He conjured them all three not to abandon him, but to take the whole weight of affairs upon their own shoulders; and declared that he would never accept the mitre upon any other terms. "If you are resolved," added he, "to make me pope, it will only be placing yourselves on the throne. For my part, I shall be satisfied with the bare title. Let the world call me pope, and I make you heartily welcome to the power and authority." The cardinals swallowed the bait, and exerted themselves so effectually that Montalto was elected. He now pulled off the mask which he had worn for fourteen years. No sooner was his election secured, than he started from his seat, flung down his staff in the middle of the hall, and appeared almost a foot taller than he had done for several years.

After his accession to the pontificate he sent for his family to Rome, with express orders that they should appear in a decent and modest manner. Accordingly his sister Camilla came thither, accompanied by her daughter and two grandchildren. Some cardinals, in order to pay court to the pope, went out to meet her, and introduced her in a very magnificent dress. Sixtus pretended not to know her, and asked two or three times who she was. Upon this one of the cardinals said, "It is your sister, holy father." "I have but one sister," replied Sixtus with a frown, "and she is a poor woman at Le Grotte; if you have introduced her in this disguise, I declare I do not know her; yet I think I would know her again, if I saw her in the clothes she used to wear."

Her conductors at last found it necessary to carry her to an inn, and strip her of her finery. When Camilla was introduced a second time, Sixtus embraced her tenderly, and said, "Now we know indeed that it is our sister; nobody shall make a princess of you but ourselves." He stipulated with his sister, that she should neither ask any favour in matters of government, nor intercede for criminals, nor interfere in the administration of justice; declaring that every request of that kind would meet with a certain refusal. These terms being agreed to, and punctually observed, he made the most ample provision, not only for Camilla, but for his whole relations.

This great man was also an encourager of learning. He caused an Italian translation of the Bible to be published, which raised a good deal of discontent amongst the Catholics. When some cardinals reproached him for his conduct in this respect, he replied, "It was published for the benefit of you cardinals who cannot read Latin."

Sixtus died in 1590, after having reigned little more than five years. His death was ascribed to poison, said to have been administered by the Spaniards; but the story seems rather improbable. It was to the indulgence of a disposition naturally formed for severity, that all the defects of this wonderful man are to be ascribed. Clemency was a stranger to his bosom; his punishments were often too cruel, and seemed sometimes to border on revenge. But though the conduct of Sixtus seldom excites love, it generally commands our esteem, and sometimes our admiration. He strenuously defended the cause of the poor, the widow, and the orphan; he never refused audience to the injured, however wretched or forlorn their appearance was. He never forgave those magistrates who were capable of partiality or corruption; nor suffered crimes to pass unpunished, whether committed by the rich or the poor. He was frugal, temperate, sober, and never neglected to reward the smallest favour which had been conferred on him before his exaltation. When he mounted the throne, the treasury was not only exhausted, but in debt; at his death it contained five millions of gold. Rome was indebted to him for several of her greatest embellishments, particularly the Vatican library; it was by him, too, that trade was first introduced into the ecclesiastical state.

SIZAR, or Sizer, in Latin *Sizator*, an appellation by which the lowest order of students in some universities are distinguished, is derived from the word *size*, which has a peculiar meaning. To *size*, in the language of the university, is to get any sort of victuals from the kitchens, which the students may want in their own rooms, or in addition to their commons in the hall, and for which they pay the cooks or butchers at the end of each quarter. A size of any thing is the smallest quantity of that thing which can be thus bought; two sizes, or a part of beef, being nearly equal to what a young person will eat of that dish to his dinner, and a size of ale or beer being equal to half an English pint. In Oxford, the order similar to that of sizar is denominated servitor, a name evidently derived from the menial duties which they perform. The sizars are not upon the foundation, and therefore whilst they continue sizars, are not capable of being elected fellows; but they may at any time, if they choose, become pensioners, and they generally sit for scholarships immediately before they take their first degrees. If successful, they are then on the foundation, and are entitled to become candidates for fellowships when they have got their degree. In the mean time, whilst they continue sizars, besides free commons they enjoy many benefactions, which have been made at different times, under the name of *sizar's prætor*, *exhibitions*, and the like, and the rate of tuition, the rent of rooms, and other things of that sort within their respective colleges, is less than to the other orders. But though their education is thus obtained at a less expence, they are not now considered as a menial order; for sizars, pensioner-scholars, and even sometimes fellow-commoners, mix together with the utmost cordiality.

SIZE, the name of an instrument used for finding the bigness of fine round pearls. It consists of thin pieces or leaves, about two inches in length, and half an inch in breadth, fastened together at one end by a rivet. In each of these are round holes drilled of different diameters. Those in the first leaf serve for measuring pearls from half a grain to seven grains; those of the second for pearls from eight grains or two carats to five carats; and those of the third, for pearls from six carats and a half to eight carats and a half.

Size, is also a sort of paint, varnish, or glue, used by painters and others. The shreds and parings of leather, parchment, or vellum, being boiled in water and strained, make size. This substance is much used in many trades. The manner of using size is to melt some of it over a gentle fire, and scraping as much whiting into it as will just colour it, let them be well incorporated together. After it dries, melt the size again, and put more whiting and whiten the frames seven or eight times, letting it dry between each time; but before it be quite dry, between each washing with size, you must smooth and wet it over with a clean brush-pencil in fair water.

SKATING, an exercise on ice, both graceful and healthy. Although the ancients were remarkable for their dexterity in most of the athletic sports, yet skating seems to have been unknown to them. It may therefore be considered as a modern invention; and probably it derived its origin in Holland, where it was practised not only as a graceful and elegant amusement, but as an expeditious mode of travelling when the lakes and canals were frozen up during winter. In Holland long journeys are made upon skates, with ease and expedition; but in general less attention is there paid to graceful and elegant movements, than to the expedition and celerity of what is called journey skating. It is only in those countries where it is considered as an amusement, that its graceful attitudes and movements can be studied; and there is no exercise whatever better calculated to set off the human figure to advantage. The acquirement of most exercises may be attained at an advanced period of life; but to become an expert skater, it is necessary to begin the practice of the art at a very early age. It is difficult to reduce the art of skating to a system. It is principally by the imitation of a good skater that a young practitioner can form his own practice. The English, though often remarkable for feats of agility upon skates, are very deficient in gracefulness, which is partly owing to the construction of the skates. They are too much curved in the surface which embraces the ice; consequently they involuntarily bring the users of them round on the outside upon a quick and small circle; whereas the skater, by using skates of a different construction, viz. less curved, has the command of his stroke, and can enlarge or diminish the circle according to his own wish and desire. The metropolis of Scotland has produced more instances of elegant skaters than perhaps any other country whatever; and the institution of a skating club has contributed not a little to the improvement of this elegant amusement.

SKELETON, in *Anatomy*, the dried bones of any animal joined together by wires, or by the natural ligament dried, in such a manner as to show their position when the creature was alive.

In the *Philosophical Transactions* we have an account of a human skeleton, all the bones of which were so united as to make but one articulation from the back to the os sacrum, and downwards a little way. On sawing some of them where they were unnaturally joined, they were found not to cohere throughout their whole substance, but only about a sixth of an inch deep all round. The figure of the trunk was crooked, the spinæ making the convex, and the inside of the vertebræ the concave part of the segment. The whole had been found in a charnel-house, and was of the size of a full-grown person.

SKENE, Sir John, a Scotish lawyer, was the second son of James Skene of Ramore, and of Janet the second daughter of Alexander Burnet of Leys. He thus derived his lineage from the ancient family of Skene of Skene. We may place his birth about the year 1540. He is said to have been partly educated at King's College, Aberdeen; but he is known to have been incorporated at St. Andrews in the year 1556; and in this university he took the degree of A.M. In 1564 and 1565 he taught as one of the regents of St. Mary's College. According to Dempster, he spent a great part of his youth in Norway, Denmark, and Poland, and had thus an opportunity of acquiring a familiar acquaintance with modern languages, as well as of extending his knowledge of men and manners.[1] Skene has incidentally mentioned that he was in Switzerland in 1568, and that he was at Cracow in Poland during the following year.[2] He has likewise stated that he returned home after a peregrination of seven years, and that he returned from the famous university of Wittemberg, honoured with an annual pension from the elector of Saxony, and imbued with some knowledge of the civil law. He appears to have begun his travels in 1567, and to have returned in 1574.[3] On revisiting his native country, he finally made choice of the legal profession, and was admitted as an advocate on the 19th of March 1575. He speedily acquired some degree of distinction as a lawyer.

The earl of Morton, then regent of the kingdom, had formed a plan for reducing the laws into a more easy form and method. The execution of the plan was committed to Skene and to Sir James Balfour, president of the court of session. Among other ostensible coadjutors, we find Lord Glammis, chancellor, Lord Ruthven, and William Baillie of Provand, who likewise attained to the dignity of president. The only result of this commission is supposed to have been the compilation of a book which passes under the title of Sir James Balfour's Practicks. "If I might be allowed to indulge in conjecture," says Mr. Thomson, "I should be inclined to suppose, that the conception or project of this digest of the laws may have originated with Balfour; that his own exile afterwards precluded him from continuing to take any part in its execution; that the active drudgery of the proposed investigation was devolved upon younger men; and that the unfinished result of their labours is perhaps no other than the volume of Practicks to which the name of Sir James Balfour has been traditionally annexed."[4] It is at least evident that the work must have been interpolated; for, as Lord Hailes has remarked, it mentions certain acts of parliament, and the names of certain peers, that did not exist till after the death of Balfour. Of this compilation, which was not printed till 1754, the value has never been highly estimated. The labours of Skene, whatever may have been their nature or extent, were, on the 10th of June 1577, rewarded by the grant of an annual pension of "ten chalders of meal," payable out of the revenues of the abbey of Aberbrothock.

In the year 1589 he was employed in another capacity. Sir James Melville was selected by the king as his ambassador to the court of Denmark, for the purpose of negociating a marriage with a Danish princess; and he required the advice and assistance of a lawyer, with a special reference to the Danish claims on Orkney. "When I schew his maieste," says Melville, "that I wald tak with me, for man of law, Mester Jhon Skein, his maieste thocht then that ther wer many better lawers. I said that he was best acquanted with the conditions of the Germanes, and culd mak them lang harangues in Latin, and was a gud trew stout man, lyk a Dutche man. Then his maieste was content that he suld ga ther with me."[5] Melville was however supplanted, and the Earl Marischal having been placed at the head of the embassy, Skene accompanied him to Denmark. Dr. Craig, physician to the king, addressed a letter to Tycho Brahe, recommending to his friendly attentions Skene, Swinton, Nicolson, and Fowler, who were all attached to this mission,

In the course of the same year, Skene was conjoined with David Makgill for executing the office of his majesty's advocate; and in 1590 he was associated with Colonel Stewart in an embassy to some of the princes of Germany.[1] During the same year he was employed on an embassy to the States-General.[2] In 1592 an act of parliament authorized the chancellor, assisted by other commissioners, of whom Skene was one, to institute a general examination of the municipal laws, to consider what laws and acts should be known to the king's subjects, and to take the necessary steps for printing them.[3] The most laborious part of this undertaking devolved upon Skene; and after an interval of five years, he published "The Lawes and Actes of Parliament maid be King Iames the First and his Svccessovrs, Kinges of Scotland: visied, collected, and extracted furth of the Register." Edinb. 15 Martii A.D. 1597, fol. According to our present mode of reckoning, the book was published in the year 1598. With a separate title, it includes a treatise "De Verborum Significatione. The Exposition of the Termes and difficill Wordes, conteined in the fovre bvikes of Regiam Majestatem, and vthers, in the Actes of Parliament, Infeftments, and vsed in practicque of this Realme, with diuerse rules and common places, or principalles of the Lawes: collected and exponed be M. Iohn Skene, Clerke of our Soveraine Lordis Register, Councell, and Rolles."

[3] In the dedication prefixed to Regiam Majestatem, Skene expresses himself thus: "Annus jam agitur tricesimus quintus, cum Dei beneficio, post septem annorum peregrinationem, ex inclyta Academia Witebergensi (quae est in Germania, sedes et domicilium bonarum literarum) Augusti Ducis et Electoris Saxoniæ annua pensione honoratus, et qualicunque juris civilis cognitione imbutus, domum redii." This dedication was printed in the year 1609.

[4] Fourth Annual Report of the Deputy Clerk Register, p. 21.

[5] Melville's Memoirs, p. 366. Edinb. 1827, 4to.

In September 1594 he had been appointed to the office of Clerk Register, in the room of Alexander Hay of Easter Kennet, whom he also succeeded as one of the Judges of the Court of Session. He was admitted on the 30th of November. For his preferment he is said to have been indebted to the influence of Walter Stewart, prior of Blantyre, who had married a sister of Skene's wife, Helen the daughter of Sir James Somerville of Cambusnethan. In 1596 he was nominated one of the commissioners of the exchequer, commonly described as the Octavians; but being viewed by the people as a dangerous junto, they relinquished their office in the course of the following year. In 1604 he was associated with other commissioners for discussing the terms of a union between the two kingdoms.

About the beginning of the year 1607 he had prepared another work for the press; and "the meanness of his estaite and fortune not answerand to his witt, ingyne, and literature," the privy council, after having examined it, addressed a letter to the king, requesting him to provide the means for its publication.[4] His manuscript was afterwards presented to parliament, and having been highly approved, was ordered to be printed. With the view of defraying the expense, and procuring some remuneration to the editor, a sum of money was ordered to be paid by the sheriffs, bailies, stewards, and other judges, and likewise by the prelates, earls, lords, and boroughs of the kingdom. A commission was appointed for the purpose of fixing the rate of the different contributions. James Carmichael, minister of Haddington, was selected as the fittest person for correcting the press; and on the 13th of October 1608, the privy council requested the presbytery to grant him leave of absence for the period of about two months.[5] This period must however have been too short for correcting one half of the work. It was at length published, under the title of "Regiam Majestatem. Scotiæ veteres Leges et Constitutiones, ex Archivis publicis et antiquis libris manuscriptis collectæ, recognitæ, et notis juris civilis, canonici, Nortmannici auctoritate confirmatis illustratæ," &c. Edinb. 1609, fol. A Scotish translation speedily followed: "Regiam Majestatem. The avld Lawes and Constitvtions of Scotland, &c., translated out of Latine in Scottish language, to the vse and knawledge of all the subjects within this Realme, with ane large table of the contents therof, be S^{r} John Skene of Curriehill, Clerk of our Soveraigne Lordis Register, Counsell, and Rollis. Qvherevnto are adjoined twa Treatises, the ane anent the Order of Proces observed before the Lords of Counsell and Session; the other of Crimes, and Judges in Criminal Causes." Edinb. 1609, fol.

The labours of Sir John Skene were highly valued by his contemporaries, who must have found them useful at a period when so little had been effected for illustrating either the principles or the history of our law. It is not however to be concealed that his publications are deficient in critical accuracy, and even in editorial fidelity. It is well known that the treatise "De Legibus et Consuetudinibus Regni Angliæ," commonly ascribed to Glanville, was at an early period adopted in Scotland, with a few changes and modifications; and that, under this new form, it bears the title of *Regiam Majestatem*, from the initial words of the prologue. Ranulph Glanville was chief justice of England during the reign of Henry the Second, and he still retained his office when Richard succeeded to the throne.[6] Sir Mathew Hale has remarked that although it perhaps was not written by him, yet it seems to have been wholly written at that time.[7] According to the title of the book, it was composed in the time of Henry the Second, "justiciæ gubernacula tenente illustri viro Ranulpho de Glanvilla;" an inscription which by no means describes the chief justice as the author. From these words, says Lord Lyttelton, I infer that the book was not written by Glanville himself, "but by some clergyman, under his direction and care; I say clergyman, because it is written in Latin, which could hardly be done but by a clergyman of that age."[8] Sir Thomas Craig easily discerned that the original work was not Scotish but English.[9] Skene was however anxious to exhibit *Regiam Majestatem* as the original, and to represent it as having been composed and divulged by the authority of David the First, who closed his reign in the year 1153. From what manuscripts he derived his text, he has not thought proper to specify; but several are to be found which contain a reference to Glanville by name. Henry, under whom he acted as chief justice, did not begin his reign till the year 1154. Lord Cromarty's MS. contains references to the gloss on the Decretals of Gregory IX. and to the Decretals of Boniface VIII.[10] The pontificate of Gregory extended from 1227 to 1241; that of Boniface from 1294 to 1303. It is sufficiently evident that a writer in the reign of David could not quote such authorities. Of this circumstance Skene was sufficiently aware; and the passages which refer to Glanville and the canon law are silently excluded from his edition. This is not merely a defect in literary accuracy; it is a want of that ordinary fidelity which every editor is bound to exercise. If he had excluded such passages from the text, and stated in the notes his reasons for rejecting them as spurious, his conduct would not have been liable to censure.

Having reached an advanced age, he became anxious to secure for his eldest son James the office of Clerk Re-

gister; but his attempt was defeated by the dexterity of Sir Thomas Hamilton, afterwards successively earl of Melrose and of Haddington. "Thinking to get his son provided to his office," says Spotswood, he "had sent him to court with a dimission of the place, but with a charge not to use it, unless he found the king willing to admit him: yet he, abused by some politick wits, made a resignation of the office, accepting an ordinary place among the Lords of Session. The office upon his resignation was presently disponed to the advocate; which grieved the father beyond all measure. And the case indeed was pitiful, and much regrated by all honest men; for he had been a man much employed, and honoured with divers legations, which he discharged with good credit, and now in age to be circumvented in this sort by the simplicity or folly of his son, 'twas held lamentable. The king being informed of the abuse by the old mans complaint, was very careful to satisfie him, and to have the son reconciled to his father, which after some travel was brought to pass: yet so exceeding was the old man's discontent, as within a few days he deceased."[1] Grief however is seldom so rapidly fatal. Skene resigned his office in the year 1612, and he survived till the 16th of March 1617.

At that period the legal profession not unfrequently opened the road to emoluments and wealth comparatively great. He acquired the demesnes of Curriehill and Redhall in the county of Edinburgh, and Edinganoch in the county of Aberdeen. His title on the bench was Lord Curriehill. His son Sir James Skene succeeded him on the 12th of June 1612, and became president of the Court of Session on the 14th of February 1626. On the 15th of October 1633, he died in his own house near the grammar school. The second son, named John, was appointed one of the principal clerks of Session in 1614. He purchased the estate of Hallyards. About twenty years ago, his last descendant, Elizabeth Skene, bequeathed to the Advocates Library a collection of family papers, together with a very curious collection of ancient music, which appears to have belonged to this ancestor. The *Skene Papers* have been carefully bound in a folio volume; and the music has very recently been published by Mr. Dauney, who has added a copious and elaborate introduction, together with notes and illustrations.[2] Alexander, the third son of Sir John Skene, was clerk of the registration of hornings. Beside these three sons, he had four daughters. The eldest daughter became the wife of Alexander Hay of Fosterseat, a judge and privy councillor. The second daughter was married to Sir William Scott of Ardross; the third to Robert Lermont, advocate, brother to Lermont of Balcomy; and the fourth to Sir Robert Richardson of Pencaitland.[3]

The clerk register had a brother named Alexander, who was likewise an advocate and an author. For some time at least, he must have adhered to the popish church; for we find that in 1561 he was committed to prison by the magistrates of Edinburgh for attending mass, but was released at the intercession of William Skene.[4] This was apparently his brother, who was commissary of St. Andrews, and professor of law in that university. Of his method of teaching, we find an account in the very curious Diary of a pupil, who relinquished the study of law for that of divinity. "In the thrid and fourt yeirs of my course, at the direction of my father. I hard the comissar, Mr. Wilyeam Skein, teatche Cicero de Legibus, and diuerss partes of the Institutiones of Justinian. I was burdet in the houss of a man of law, a verie guid honest man, Andro Greine be nam, wha louit me exceiding weill, whase wyff also was an of my mothers [freinds]: I am sure sche haid nocht sone nor bern sche loued better. This lawier tuk me to the consistorie with him, whar the comissar wald tak pleasour to schaw ws the practise in judgment of that quhilk he teatched in the scholles. He was a man of skill and guid conscience in his calling, lernit and diligent in his profession, and tuk delyt in na thing mair nor to repeat ower and ower again to anie schollar that wald ask him the things he haid bein teatching."[5] (x.)

Skew Bridge.

General observations.

SKEW BRIDGE. Square arches, or those which stand at right angles to their abutments, and exert their thrust in that direction, have been already treated at considerable length under the article BRIDGE. Till lately, any other form of arch was rarely to be met with. But there are cases of frequent occurrence, in which various sorts of passages and courses necessarily cross each other obliquely, as well as on different levels;[6] and where, on account of the difficulty or impossibility of constructing a square bridge, which should both have sufficient strength, and, at the same time, leave the lower passage quite clear, a different form of arch, placed obliquely to the abutments, and yet exerting its thrust in the direction of the upper passage, is almost the only practicable alternative. Such a structure is called a *skew* bridge, and is very frequently required since the more general introduction of railways, in which it is of great consequence to preserve as direct or straight a line as possible. Nay, it is not uncommon for a railway to have to traverse districts in which it may neither be allowable nor practicable to use any means of avoiding the obliquity with which it may have to cross canals, roads, &c.; its course being so much controlled by conflicting interests, and by the natural features of the country.

If a common square bridge were to be employed in the circumstances just supposed, namely, in which the passages mutually intersecting obliquely, cannot be so diverted as to cross at right angles, then the arch must either be built stretching in the direction of the upper passage, and of sufficient span to allow the lower passage, with its course unaltered, to pass uninterruptedly under it; or, it must be built stretching at right angles to the lower passage, and having its embankments and abutments so much extended, that the whole structure may both stand securely, and furnish sufficient area above for the upper passage to continue its oblique course over it unaltered. An arch partaking of both these forms might, it is true, be employed; but to such expedients, a proper skew bridge is in general greatly preferable, and is indeed sometimes the only allowable form of construction that will serve the purpose required. As for any alteration in the old courses, they would often be incompatible with the particular or vested rights of proprietors, and especially with the provisions which are generally inserted in the acts of Parliament expressly prohibiting any alteration to be made in the original courses of canals, &c.; and even were there no such restrictions, the diversion of the courses might be attended with great expense, and might occasion much inconvenience to the traffic. The wide or broad arch again, is a most unscientific mode of overcoming the difficulty. Room for it, with the requisite embankments, could not always be had, and it would, besides, greatly increase the expense, owing to the necessity of constructing a bridge of much larger dimensions than would be required were a proper oblique arch introduced, which, from its exerting its thrust in the most advantageous direction, is stronger than any other of the same magnitude. For, besides endeavouring to preserve a certain degree of equilibrium amongst the several parts of an arch,[1] it is considered still more necessary to the insuring the greatest strength, especially where the span is considerable, and the upper passage narrow, that the beds of the courses of the stones should be everywhere at right angles, both to the soffit or under surface of the arch, and also to every vertical plane running in the direction of the road or other passage carried over the bridge. There is no difficulty in fulfilling or combining these conditions in a square bridge, but it is very different with the oblique sort.

[6] Indeed to avoid interruptions and accidents, it is always desirable that any crossings with a railway should take place on different levels. The like may be said of canals, which besides, cannot, without some kind of moveable bridges, be crossed closely above by any sort of road, and in fact can only be crossed quite on the same level by some water course; not to say any thing of fording or wading through them.

The screw thread arch

Writers on the theory of bridges for the most part say nothing of the oblique arch; and the few who do mention it, generally content themselves with slurring it over in such brief, vague, or general terms, as to be nearly unintelligible. Those again who have professedly drawn up, what they reckon practical rules for workmen, have, for the most part, tacitly assumed it as perfectly ascertained and indisputable, that the conditions above mentioned may, with only a little more labour, be equally well attained in the case of the oblique, as in that of the square bridge, by merely making the courses of the stones to form portions of the thread of a square threaded screw, or rather, perhaps, of a thread somewhat of the dovetailed form; the highest part of each thread, or that on the crown of the arch, being at right angles to the direction of the road. Such, in particular, is the doctrine laid down by Mr. Nicholson, and also by Mr. Fox; and it is not a little amusing, that the honour of inventing this supposed valuable theory has been warmly disputed between these gentlemen, or at least their friends.[2] When the soffit is to be a cylindrical surface, the side of the screw-thread may, it is true, be readily formed so as to be everywhere at right angles to the soffit; and, as all the beds of the courses of the stones would have the same curvature, the stones might be conveniently prepared beforehand, which is a great recommendation to the scheme. But unfortunately, the other, and by far the more important condition of the two, namely, to have the beds of the courses everywhere at right angles to the direction of the upper passage, can by no means be accurately fulfilled by the figure of the screw; for no two parallel planes can both of them cut the same thread of the screw at right angles, if they intercept a less portion of it than a revolution, so that a thread which has the proper position or direction at the crown of the arch, can have it at no other point; its direction on the one side of the crown being too much inclined to the course of the under passage, whilst, on the other side, it is too little inclined.

Its defects.

However, although it thus appears that the principle of the screw thread cannot well serve the purpose of the skew bridge, especially when the obliquity is great; yet there can be no question that the beds of the courses of the stones might always be formed with such a curvature as would make them very nearly fulfil both the conditions above specified; but as the several parts of this curved surface, if different from that of a screw, would necessarily be far from being uniform, the stones, owing to their requiring to be of so many different shapes, could not, without immense labour of measurements, drawings, and innumerable patterns, be prepared beforehand; and, therefore, most probably, the easiest way of putting such a scheme in practice, would be to prepare the stones no faster than they are required in building, and then it would be easy to form each stone in such a manner, that two of its opposite sides, or at least the middle parts of these sides, should be as nearly as possible at right angles, both to the soffit, and also to the direction of the passage over the bridge. In this way of working, the soffit need not be restricted to the cylindrical form, because it may suit equally well though of a very different figure. We are aware, that something similar to the method just mentioned has been already acted on, and has also been heartily ridiculed as unscientific and unsystematic; but it will be quite in time to condemn it when once a better shall have been substituted in its stead: for, most assuredly, if closely followed up, it should form an incomparably more perfect structure than that with the screw thread. The like remarks are equally applicable when the material is brick.

Some bridges may be said to consist generally of a platform supported by a set of curved iron ribs, which either abut like a stone arch against the piers, or, if the curvature be small, and especially if there be nothing to abut against, each rib has its extremities connected and kept from spreading, by a straight rod crossing the span underneath. Ribs of this last construction are often used as beams for supporting floors in large buildings; for, being in effect beams of great depth, they only rest or press downwards upon the piers or walls supporting them, and so have no horizontal thrust. Curved iron ribs, whether with or without the rods, are equally applicable to the oblique as to the square arch, since each rib may always be placed in a plane, which is both vertical, and runs in the direction of the upper passage. The horizontal rods, though generally of unnecessarily great strength throughout the most part of their length, are commonly rendered very weak near their extremities, owing to their either being very needlessly pierced with large holes near the ends, or by being very much reduced there, for the purpose of being formed into a screw. Common sense, one would think, could not fail to hint to even the most inexperienced, that to resist a longitudinal pull, there is no use in having one part of the rod stronger than another; because one weak part will render it as likely to fail, as if the whole were equally weak. Neither is it necessary that such rods should be stronger at the middle to sustain their own weight, since they are commonly suspended there by a vertical strap.

It is evident that the opposite horizontal thrusts of an arch, formed of any other materials as well as iron, might, in a similar manner, be made to annihilate or counteract each other by means of horizontal rods beneath, so that a common square arch, having the thrusts obviated in this way, could be used instead of a skew bridge, wherever there is sufficient head-room for the horizontal rods, and likewise space for carrying out a mere wall as far as will square the faces of the arch, and support its weight at the two projecting corners; no additional embankment being required where there is no thrust.

Mr. nel's arch

An elegant mode of constructing arches of brick, without requiring the aid of anything like ordinary centring on the great scale, has been introduced by Mr. Brunel, and is equally applicable to the oblique as to the square bridge. The principle of this, as originally adopted, and its sufficiency tested in constructing the shaft of the Thames Tunnel, depends on the cohesive power of Roman cement, coupled with a system of ties, the most eligible material for which Mr. Brunel found to be hoop iron. After the piers have been constructed in the usual manner, a mould, curved according to the figure of the arch, is fixed to, and stretched between these piers, and upon this a narrow arch or rib of brick is carried over and keyed, using cement, with the occasional insertion of ties. The adhesion of the cement to the brick being greater than the cohesion of the brick itself, enables the rib to be carried to any extent of which the strength of the material will admit. When once a sufficient number of such ribs have been successively constructed, side by side, like so many beams stretched between the piers, they will be in a state to receive and support all the other materials necessary to complete the structure.

---

[1] The mode of attaining an equilibrium in an oblique arch, is a subject on which no one, so far as we know, has entered. It seems generally to be taken for granted, that the obliquity makes no difference; but though in this we cannot acquiesce, our limits will not admit of attempting to discuss the question

[2] See Philosophical Magazine for April 1836, January and March 1837, and Reports of British Association for 1838.

The bridge of the Santissima Trinita at Florence, though of ruble construction, affords a magnificent example of the strength of cementitious architecture, and of the durability of the materials; the arches being composed of a mass of irregular stones so strongly united by mortar, as to have the consistence of a single stone. It is evidently a matter of perfect indifference whether such arches were square or oblique. A very ancient bridge, said to have been built by the Romans, over the Danube at Ratisbon, has wonderfully resisted the ravages of time. It consists of gray freestone and thin bricks, firmly united by pozzolano cement.

On several lines of railway, an ingenious mode of constructing arches of laminated ribs of wood or iron has been introduced by Mr. Green, and is alike applicable to the oblique as to the square arch. At the Ouseburn, close to the east side of the town of Newcastle, is one of the great viaducts constructed in this manner by Mr. Green, on the Shields railway. The piers and abutments are of stone, with large projecting buttresses on each side, whilst the arches, which are circular, are of Memel timber. Each arch is one hundred and sixteen feet in span, and consists of three separate and parallel curved ribs, and each rib, which is four feet in depth by twenty-two inches in thickness, is composed of sixteen layers of three-inch planks laminating over each other, and these again, whilst being bent over a curved frame or centre into the form of the required arch, were firmly fixed together by means of oaken pins and iron straps. The three ribs of each arch are connected by diagonal braces, and their ends rest in large iron sockets fixed on the stone piers or abutments. From the upper sides of the ribs a series of very strong struts, braces, and framing, bound with iron straps and bolts, is carried up, filling the spandrils, to support the platform or roadway, which is formed of longitudinal beams; these again are covered with three-inch planks to carry the rails. Hitherto almost all wooden bridges had been constructed of straight timbers, upon the same principles as are used in roofing; and on account of the shrinkage from the frequent joggles and the weight of the structure, the roadway and framing generally became bent or crippled. But the ribs constructed by Mr. Green make a very close approach to solid pieces of timber. Their strength is very little impaired by the joining of the planks, which are from twenty to forty-five feet in length by eleven inches in breadth; particularly since great care has been taken that no two junctions of their ends might occur at the same place. In forming a rib, the first layer of planks consists of two whole deals in breadth, and the next of one whole and two half deals, and so on alternately, until the rib is completed. This construction is supposed to be better able to resist the load which it may have to bear at a given point, than can be done by the same quantity of materials in a different form. The struts which discharge the weight from the spandril beams upon the ribs, stand at right angles to the latter, and divide them into equal parts. The strength, durability, and beauty, can only be exceeded by arches of stone. The whole of the timber was subjected to Kyan's process, and between every two deals was introduced a layer of brown paper dipped in tar, to exclude moisture. The bridge across the Ouseburn has five wooden arches of one hundred and sixteen feet span, and four of stone of forty-three feet span. Each of the wooden arches required three centres, which were made so light as to admit of being shifted from one arch to another without being taken to pieces. The total length of this bridge is nine hundred and fifty feet, and greatest height one hundred and eight feet. At Willington, four miles farther east, on the same railway, is a still longer bridge of the same construction.

Mr. Green has applied the same principle to the construction of iron bridges with laminated ribs of that metal. Wrought iron bars from 1·5 to 4 inches square, according to the span of the arch, and from fifteen to twenty-five feet in length, grooved on the under, and tongued on the upper side, are laid one over another, and bent over a centre until the rib is formed. The bars are bound together with iron straps at intervals of from four to six feet apart. A considerable saving of expense, and great lightness, as compared with stone or ordinary iron bridges, may thus be attained.

Skinner.

SKINNER, John, a poet and theologian, was born at Balfour in the parish of Birse and county of Aberdeen, on the third day of October 1721. His father, who bore the same name, was master of the parochial school, and had married Jane the widow of Donald Farquharson, Esq. of Balfour, grandfather to the late Dr. Farquharson of Edinburgh. The mother, whose maiden name was Gillanders, died about two years after the birth of this their only son; and Mr. Skinner afterwards removed to the parish of Echt, at the distance of about twelve miles from Aberdeen. Here he continued for fifty years to discharge the duties of a schoolmaster, "to the entire satisfaction of many persons of distinction, whose sons were entrusted to his care and tuition; and so great was his diligence in the line of his profession, that he fitted out more young men for the university, than most country schoolmasters of his day." After having continued a widower for several years, he contracted a second marriage, and had a numerous family. His youngest son, Mr. James Skinner, a solicitor of Edinburgh, still survives, and has reached a very advanced age.

For the rudiments of learning, John was indebted to his father's school, where he made rapid progress in the acquisition of the Latin language. At the early age of thirteen, he was emboldened to present himself at the annual competition in Marischal College; and there he gained a considerable *bursary*, or exhibition, which served to defray a great proportion of his expenses during the four years of his academical course. After the completion of this period, he was for a few months employed as a teacher in Kemnay school; from which he transferred his services to the adjoining parish of Monymusk, as an assistant to the schoolmaster. Lady Grant, admiring some of his poetical effusions in the Scottish dialect, "was pleased to encourage his rustic muse, by affording him in the house of Monymusk every accommodation for prosecuting his studies, and improving his mind in the attainment of useful learning. Here it was, that enjoying the conversation, and the benefit of reading under the direction of a worthy episcopal clergyman in that neighbourhood, he became a convert to the principles of episcopacy, and united himself to the venerable remains of the old established church of Scotland." This *venerable* church was, at that period, chiefly distinguished by a narrow bigotry in politics, as well as religion. In the month of June 1740, he became tutor to the only son of Mr. Sinclair of Scalloway, a gentleman of considerable property in Zetland. Here he only resided for about twelve months, the death of his pupil's father having occasioned another arrangement. He honoured his memory by an English elegy and a Latin epitaph, both of which were printed by Ruddiman. Here he became intimately acquainted with Mr. Hunter, the only episcopal clergyman in those islands, who not only assisted him in his theological studies, but likewise bestowed upon him the hand of his eldest daughter; "and with her the best of all earthly blessings, a sweetly soothing affectionate wife, who was his dear companion, and ministered tenderly to all his wants, for the uncommon space of fifty-eight years." This marriage must have taken place when he had scarcely attained the twentieth year of his age.

Having now returned to Aberdeenshire, and made some further preparation, he received ordination from Bishop Dunbar, who resided at Peterhead. In November 1742 he fixed his residence at Linshart in the parish of Longside, as minister of a congregation which his biographer describes as large and respectable.[1] It is not however to be supposed that his stipend was very ample. The rebellion, which ensued in 1745, exposed him to no small annoyance. The episcopal clergy were very generally disaffected to the existing government, and many of them were subjected to useless severities. On returning home one evening, Mr. Skinner "found his house in the possession of a military party; some of them guarding the door with fixed bayonets, and others searching the several apartments, even the bedchamber where Mrs. Skinner was lying-in of her fifth child, and little able to bear such a rude unseasonable visit. No lenity was to be looked for from such unfeeling visitors, who pillaged the house of every thing they could carry with them, hardly leaving a change of linen to father, mother, or child in the family. The chapel with all its furniture was destroyed; and for several years the congregation could find no place to meet in for public worship but the clergyman's house, which not being sufficiently large, many of them were obliged to stand in the open air, during divine service." Of this miserable species of persecution, it is not easy to devise any plausible justification. The episcopalians of Longside, even if we suppose all of them to have been the most decided Jacobites, certainly could not convert their chapel to any political or military purpose; nor is it very obvious how this mode of treatment could have any tendency to increase their attachment to the reigning family. With the view of preventing his flock from being scattered from the true fold, he now prepared a small tract, entitled "A Preservative against Presbytery," which was printed in the year 1746.

In the course of the same year, an act of parliament enjoined the episcopal clergy to register their letters of orders before the first day of September; after which date, it was provided that none should be admitted for registration, except such as had been obtained from a bishop of the church of England or of Ireland. And another act, passed two years afterwards, declared that no letters of orders, unless such as were granted by bishops of those churches, should after the 29th of September be sufficient to qualify any minister of an episcopalian meeting. From such vexatious and unavailing regulations as these, many hardships must have resulted, and Skinner seems to have experienced his full share. In 1753 he was apprehended under the authority of a warrant from the sheriff-substitute of the county; nor did he hesitate to make a voluntary confession that he had violated the recent act, by officiating as a clergyman to more than four persons, beside the members of his own family. For this offence he was sentenced to six months imprisonment. His wife, with her six children, were in the mean time kindly treated by the good people of Longside. The solitude of his prison was enlivened by the visits of some faithful friends, to whom he was likewise indebted for a liberal supply of books. His literary ardour did not suffer any abatement; and he frequently declared that no six months of his life had ever passed with so little interruption to his studies and improvement. In the exercise of his poetical talents he found a pleasing recreation, but his attention was chiefly directed to more serious pursuits.

For several years he had devoted much of his leisure to the study of the Hebrew language; and during his prison hours he formed the design of his Dissertation on the Shechinah, which appeared amongst his posthumous works. In the year 1757 he published at London "A Dissertation on Jacob's Prophecy, Genesis xix. 10." According to his interpretation, this prophecy denotes "that the *tribeship* should not depart from Judah, nor a *typifer* from between his feet, or from among his descendants, till Shiloh (the Messiah) should come, and till the gathering of the people should be to him." This explanation, we are informed, was highly approved by Bishop Sherlock, and by other biblical critics of acknowledged eminence. His next work was of a different denomination. Mr. Sievwright, an episcopal minister of Brechin, published a somewhat curious volume, exposing the principles and practices of his nonjuring brethren.[2] It appeared in 1767, and Mr. Skinner soon afterwards published, but without his name, "A Letter to Norman Sievwright, M.A., in Vindication of the Episcopal Clergy of Scotland from his Charge of Innovations in Politics and Religion." Of his next publication, neither the date nor the precise title is mentioned by his biographer. It however assumed the form of an answer to an Enquiry into the Powers of Ecclesiastics, on the Principles of Scripture and Reason, written by the Rev. Thomas Gordon, minister of Speymouth.

This was followed by a more elaborate work, "An Ecclesiastical History of Scotland, from the first appearance of Christianity in that kingdom, to the present time: with remarks on the most important occurrences. In a Series of Letters to a Friend." Lond. 1788, 2 vols. 8vo. Prefixed is a dedication, in Latin verse, to his son the bishop. The value of this work is far from being considerable. It is written in a spirit too sectarian, and in a style too provincial. Many facts are very inaccurately stated. Thus he asserts that with the exception of Dr. Featley, no episcopalian divine ever sat in the Westminster assembly. According to this ecclesiastical historian, the praise of Archbishop Laud "is and ever will be in the English church." A man who could thus bestow commendation on a merciless bigot, is not to be admired for his wisdom or moderation. Nothing is so apt as bigotry to blind a man's understanding, and to suppress the best feelings of his heart. In the nefarious sentence of death pronounced on the earl of Argyle for adding an explanation when he took the test-oath, Mr. Skinner finds nothing to condemn. According to the same authority, King James's attachment to popery was acknowledged by his greatest enemies to be the only blemish of his character. The sufferings of the episcopal clergy after the Revolution are commemorated in terms sufficiently tragical; but the bloody persecution of the presbyterians during the reign of Charles the Second is represented as a very trivial matter; and it seems to have been the author's deliberate opinion, that they were treated neither better nor worse than they deserved. A very different opinion was entertained by a more impartial, as well as a more able writer. "Scotland," says Jonathan Edwards, "has also been the scene, for many years together, of cruelties and blood by the hands of high-churchmen, such as came very little short of the popish persecution in Queen Mary's days, and in many things much exceeded it."[1] Mr. Skinner is lively where he is not edifying or instructive; and if he is here entitled to any other praise, it is that of supplying an account of his own sect from the era of the Revolution. A supplementary volume, under the title of "Annals of Scottish Episcopacy," was published at Edinburgh in 1818 by the author's grandson the Rev. John Skinner of Forfar.

---

[1] During the following year, he wrote a Latin elegy on the death of Bishop Rattray, which appeared in a small publication entitled "A Letter to a Friend: with two Poems sacred to the memory of the late R. R. Dr. Thomas Rattray of Craighall, Bishop of Edinburgh." Edinb. 1743, 4to. The letter was also written by Skinner. This elegy is followed by an English poem, written by a different person.

[2] Principles, Political and Religious: or, a Preservative against Innovations in Politics and Religion. By Norman Sievwright, M.A. a Presbyter of the Communion of the Church of England as by Law established, and Minister to the authorised Episcopal Congregation in Brechin. Edinb. 1767 12mo.

Towards the close of the century, he published "a Letter to the Congregation of the Chapel of Old Deer;" and "Some plain Remarks on a plain Account of Conversion, now in circulation through the Parish and Neighbourhood of Old Deer." This last tract, printed in 1799, is directed against William Ward, A.M., a clergyman of the church of England. He continued to augment his stores of theological learning, and undertook some more laborious works, which were not however published till after the death of the author. His name was favourably known to many distinguished individuals in England, as well as Scotland. As a poet, he corresponded with Burns; as a man of erudition, with Doig. The master of Stirling school and the minister of Longside chapel were both remarkable men in their generation; and to those who complain of the want of leisure, opportunities, and encouragement in the pursuit of learning, their history supplies a most edifying example. During the summer of 1795, Dr. Doig and Mr. Ramsay of Ochtertyre paid him a visit; and he spent a delightful week with them at Peterhead, which was then a watering place of fashionable resort.

Of the activity, as well as the benevolence of his disposition, he exhibited a signal proof by devoting a portion of his time to the study of physic, not for his own benefit, but for that of his poor neighbours, whether episcopalians or presbyterians. "Nor was it only to those," says his biographer, "who were placed more immediately under his pastoral care, that his benevolence was extended. Though he always considered them as entitled to his first and principal concern, yet did he never feel himself more happily employed, than when administering relief to the distresses, whether bodily or mental, of all that were within his reach, and would listen to his advice, whatever might be their religious profession. As no medical practitioner resided within four or five miles of Longside, soon after his settlement there, Mr. Skinner's sympathy was often excited by perceiving his neighbours suffering under a want, of which the state of the country afforded no prospect of a regular supply. He resolved therefore to devote part of his own time to the study of physic; and with the aid of an eminent physician in Aberdeen [Dr. Thomas Livingston], who approved of his design, and felt the force of the motives from which it sprung, he soon acquired such a knowledge of the healing art, as enabled him to afford to the poor, labouring under disease, that relief which they could not otherwise have easily obtained, and the want of which might sometimes have proved fatal. It is proper to add, that for his medical prescriptions he accepted no fees."

During the autumn of 1799 he had the heavy misfortune to lose his wife. This was a loss which could not be repaired; and at length, when the weight of age pressed more heavily upon him, his only surviving son Bishop Skinner invited him to spend the remainder of his days under his roof. He accordingly removed to Aberdeen on the 4th of June 1807, and for about eight days he apparently enjoyed his usual health and spirits. Some feverish symptoms, with a difficulty of respiration, afterwards supervened: but during the last day of his life, he moved into the garden, when finding his strength to be totally impaired, and having with much difficulty been supported into the house, he was placed in a chair, and calmly closing his eyes, expired without a groan or a struggle. He thus departed on the 16th of June, in the eighty-sixth year of his age. In compliance with his own request, his remains were interred in the church-yard of Longside, in the same grave with those of his wife. A marble tablet was there erected by the members of his congregation, by whom his memory was much revered.

Skinner appears to have been a man of a cheerful and friendly disposition; and in the discharge of his pastoral duties, he is represented as very exemplary. During the greater part of his professional life, it was not his practice to commit his discourses to writing, but he nevertheless preached with much ease and fluency. His opinions were deeply tinctured with the Hutchinsonian philosophy. To a lively fancy he added no despicable share of learning. He had cultivated not only a knowledge of the Latin and Greek, but likewise of the Hebrew language. In the composition of Latin verse he had attained to great facility, and to considerable skill. The longest of his poems is a Latin version of the Batrachomyomachia ascribed to Homer. He likewise translated Christis Kirk of the Grene, a Scotish poem remarkable for its genuine humour. The measure which he has here adopted, hexameter and pentameter verse, is not peculiarly suited to so familiar and ludicrous a subject: iambics would certainly have been more appropriate. Some of his Scotish poems are written in a pleasant strain, and three of his songs, Tullochgorum, John o' Badenyon, and the Ewie wi' the crookit Horn, have obtained a great share of popularity.

Not long after his death appeared "Theological Works of the late Rev. John Skinner, Episcopal Clergyman in Longside, Aberdeenshire. To which is prefixed a biographical memoir of the author." Aberdeen, 1809, 2 vols. 8vo. This publication was accompanied or immediately followed by "A miscellaneous Collection of Fugitive Pieces of Poetry, &c. Vol. III. of his Posthumous Works." Edinburgh, 1809. A separate edition of his poems was published under the title of "Amusements of Leisure Hours: or, Poetical Pieces, chiefly in the Scottish dialect." Edinburgh, 1809, 12mo. A copious life of the author, evidently written by his son, is prefixed to the theological works. The first volume likewise includes a series of "Letters addressed to Candidates for Holy Orders in the *Episcopal Church of Scotland*." The second contains "A Dissertation on the Shechinah, or Divine Presence with the Church or People of God," "An Essay towards a literal or true radical Exposition of the Song of Songs, which is Solomon's," and "Psalms viii., xxiii., and xlv. translated into Latin verse." In his Essay he strenuously maintains the opinion of those who regard the Song of Solomon as an inspired book. Of the value of his Dissertation, some notion may perhaps be formed from a single specimen. The divine presence, says this learned theologian, "is not now to be looked for, but in the way of God's own divine appointment, and under the sacred symbols of bread and wine, set apart and instituted for that very purpose by Christ himself. . . . And if Corah and his company met with so signal and sudden a punishment for invading but a part of Aaron's office, of how much sorer punishment shall they be thought worthy, as St. Paul argues in a like case, who dare thrust themselves, without any call, order, or commission, into the ministry of the Christian priesthood, and will take upon them to consecrate the symbols of the divine presence, and to stand as priests between God and the people? It is no wonder that such unruly invaders of the priesthood should do what they can to bring the sacrament of the divine presence into contempt, and should refuse to appear in any posture of adoration before it, since they cannot but know that God will not vouchsafe to be present in it, but in the way and method of his own appointment." According to this pure and enlightened theology, the divine presence, utterly withheld from all non-episcopalian assemblies of worshippers, is regularly manifested wherever a popish or half-popish priest "offers the unbloody sacrifice." It is truly pitiful that any man, calling himself a protestant, should be so besotted as to represent all this as the way and method of God's own appointment. It is the very essence of such an adulterated form of Christianity, that, without the supplementary aid of bishops and priests, Christ has died in vain, and in vain has risen from the dead. (x.)

[1] Edwards's History of the Work of Redemption, p. 291. Edinb. 1774, 8vo

Skinner, *Stephen*, an English lexicographer, was born in the year 1622. He travelled, and studied in several foreign universities during the civil wars; and in 1654, he returned and settled at Lincoln, where he practised physic with success until the year 1667, when he died of a malignant fever. His posthumous work was published in folio in 1671, by Mr. Henshaw, under the title of *Etymologicon Linguæ Anglicanæ*.

SKIPTON, commonly called Skipton in Craven. It is in the wapentake of Staincliffe, in the West Riding of Yorkshire, 216 miles from London. It stands on the river Aire, in a wild and romantic district near two lofty mountains. Being on the canal from Leeds to Liverpool it has some trade with both these places, and of late years it has become the seat of some manufactures of glass, of silk, and of cotton goods. The ancient castle has been preserved, and is now a mansion of the Earl of Thanet. The quarter sessions for the West Riding are held here. It has a well supplied market on Saturdays, and several fairs for the sale of cattle. The inhabitants were, in 1801, 2305; in 1811, 2868; in 1821, 3411; and in 1831, 4181.

SKIROS, an island of Turkey, on the western side of the Archipelago, about twenty-three miles from the mainland. It is sixty-three square miles in extent, and contains 1800 Greek inhabitants, who grow oil and cotton, and feed cattle in the valleys between the rocky hills which cover the greater part of the surface. The chief town is of the same name, and has a small harbour.

SKYE, the largest of the western islands of Scotland, is situated between the outer range of the Hebrides, and the mainland of Scotland, from which it is separated by a narrow strait, varying from a gun-shot to three miles in breadth. It forms part of the county of Inverness, and is divided into seven parishes. The extreme length of the island is about forty-five miles, and its extreme breadth twenty-four miles; but a better idea of its dimensions will be formed, by measuring it across the middle, which will give a mean breadth of fifteen miles. These measurements do not, however, give any idea of the superficial extent of the island, in consequence of the remarkable indentations of the coast, no part of the island being distant four miles from the seashore. The area of the island is computed at 700 square miles, and contains therefore 448,000 acres, of which 30,000 are arable. It is divided into five districts. The south-east district, which is close upon the mainland, is called Sleat. The greater portion of the central part of the island is named Minginish, whilst the northern extremity is divided by Loch Snizort and Loch Follart into three extensive tracts of land, called Trotternish, on the north-eastern, Waternish on the north-west, and Kilmuir on the west side.

The position of Skye protects it in some measure from the storms that assail the outer range of islands. The numerous lochs provide it with a variety of excellent bays and harbours, which point it out as admirably adapted for carrying on the fisheries, but which, from the habits of the people, has never been prosecuted to any extent. The surface of the island is invariably hilly, and may be called one great mountainous moorland, presenting three distinct assemblages of mountains, which are separated by intervening tracts of high and undulating land. Kilmuir plain, and a small tract of land near Loch Braccadale, are the only exceptions.

In that part of the country, in the southern border of Minginish, occurs the greatest assemblage of mountains. They are divided into two portions, intimately united, but characterised by striking differences in their external outlines and general features. The range called the Cuchullins, so often mentioned by Ossian, average in height from 2000 to 3000 feet above the level of the sea. On the west side of the island, the land is from 600 to 1000 feet in height, and its surface is covered with brown heath. The north-eastern portion of the island, Trotternish, offers more variety, and it attains an altitude of 2000 feet in height. The shore scenery is famed for the caves with which they abound, and the mountainous parts of the island for wild and rugged scenery, equal in grandeur to any in the Highlands.

The south-east portion of the island, from the point of Sleat to Kyle-rhea, consists of regular stratified rock, which, whether primary or secondary, extend in a line from south-west to north-east; but the remaining mass of the island must be considered as formed of unstratified rock, all belonging to the family of trap, (including under that term syenite), and all incumbent on the stratified rocks, and of posterior date.

From the height of the hills, and the proximity of the sea, the air seldom continues long of the same temperature; sometimes it is dry, oftener moist, and in the latter end of winter and beginning of spring cold and piercing. At an average, three days in twelve, throughout the whole year, are scarcely free from rain, far less from clouds. These, attracted by the hills, sometimes break in useful and refreshing showers; at other times suddenly bursting, they pour down their contents with tremendous noise, and impetuous torrents deluge the plains below, and render the smallest rivulet impassable, which, together with the stormy winds so common in this country in the months of August and September, frequently blast the hopes of the husbandman. Snow has been often known to lie on the ground from three to seven weeks.

Skye is not well adapted for agriculture. The soil is good, but too light for the culture of wheat; oats are raised in considerable quantities, which, with barley and potatoes, form the agricultural produce of the island. Much might be done in the improvement of the land, for the subsoil is every where of the finest quality, and both in the trap and the gneiss districts, the calcareous rock is found to be decomposed to the depth of several feet, and yielding a loam of excellent quality. The greater part, however, is suffocated with peat or stones, and is swampy and rocky. The peat is nevertheless thin, and by burning the peat, and turning up the rock, either by manual labour, or by the subsoil plough, and proper drainage, the agriculture of the island, in course of time, would be much improved. The land is also rendered cold by the want of trees, for which the soil and climate are well adapted. Skye is unquestionably a grazing country, and the proprietors have wisely directed their attention to the improvement of the stock of black cattle and sheep, and to the enlargement of their farms, of which they have latterly in many places given leases. Kelp in former years was manufactured to a considerable extent, but that branch of industry is now nearly annihilated. The climate is, as already stated, damp, and the farmers in consequence are all provided with wattled barns, in which they may dry their scanty crops in the rainy season. The *caschrome*, or ancient crooked spade, is a good deal used by the poor, and the *quern*, or handmill, is still to be found in some of the remote districts of the island. The roads in Skye are much superior to those of Mull, and they traverse the island in various directions.

The people are of short stature, robust, and healthy. They generally profess the Protestat religion; but education is in a very low state. In 1831, one half of the population were unable to read in any language. Great numbers have lately emigrated to America. The towns in Skye are of no importance. The population in 1821 amounted to 20,627; and in 1831, to 22,796, of whom 11,883 were females.

There are two or three fairs held annually at Portree, the principal town, to which almost every part of Skye sends cattle. The commodities which are sold there are horses, cows, sheep, goats, hides, butter, cheese, fish, and wool. In Skye appear many ruins of Danish forts, watch-towers, beacons, temples, and sepulchral monuments. All the forts are known by the term Dun; such as Dun-Skudborg, Dun-Derig, Dun-Skeriness, Dun-David, and so on.

SLACKEN, in *Metallurgy*, a term used by miners to express a spongy and semivitrified substance which is mixed with the ores of metals, to prevent their fusion. It is the scoria or scum separated from the surface of the former fusions of metals. To this is frequently added limestone, and sometimes a kind of coarse iron ore, in the running of the poorer gold ores.

SLAVERY is a word, of which, though generally understood, it is not easy to give a proper definition. An excellent moral writer has defined it to be "an obligation to labour for the benefit of the master, without the contract or consent of the servant." But may not he be properly called a slave, who has given up his freedom to discharge a debt which he could not otherwise pay, or who has thrown it away at a game of hazard? In many nations, debts have been legally discharged in this manner; and in some savage tribes, it is no uncommon thing for a man, after having lost at play all his other property, to stake, on a single throw of dice, himself, his wife, and his children. That persons who have thus lost their liberty are slaves, will hardly be denied; and surely the infatuated gamester is a slave by his own contract. The debtor, too, if he was aware of the law, and contracted debts larger than he could reasonably expect to be able to pay, may justly be considered as having come under an obligation to labour for the benefit of a master with his own consent; for every man is answerable for all the known consequences of his voluntary actions.

But this definition of slavery seems to be defective as well as inaccurate. A man may be under an obligation to labour through life for the benefit of a master, and yet that master have no right to dispose of him by sale, or in any other way to make him the property of a third person; but the word slave, as used amongst us, always denotes a person who may be bought and sold like a beast in the market.[1]

As nothing can be more evident than that all men have, by the law of nature, an equal right to life, liberty, and the produce of their own labour, it is not easy to conceive what can have first led one part of them to imagine that they had a right to enslave another. Inequalities of rank are indeed inevitable in civil society; and from them results that servitude which is founded in contract, and is of temporary duration. He who has much property has many things to attend to, and must be disposed to hire persons to assist and serve him; whilst those who have little or no property must be equally willing to be hired for that purpose. And if the master be kind, and the servant faithful, they will both be happier in this connection than they could have been out of it. But from a state of servitude, where the slave is at the absolute disposal of his master in all things, and may be transferred without his own consent from one proprietor to another, like an ox or an ass, happiness must be for ever banished. How then came a traffic so unnatural and unjust as that of slaves, to be originally introduced into the world?

The common answer to this question is, that it took its rise amongst savages, who, in their frequent wars with each other, either massacred their captives in cold blood, or condemned them to perpetual slavery. In support of this opinion etymologists observe, that the Latin word *servus*, which signifies not a hired servant, but a *slave*, is derived from *servare*, to preserve; and that such men were called *servi*, because they were captives, whose lives were preserved on the condition of their becoming the property of the victor.

Origin of slavery.

That slavery had its origin from war, we think extremely probable, nor are we inclined to controvert this etymology of the word *servus;* but the traffic in men prevailed almost universally, long before the Latin language or Roman name was heard of; and there is no good evidence that it began amongst savages. The word עבד, in the Old Testament, which in our version is rendered servant, signifies literally a slave, either born in the family or bought with money, in contradistinction to שביר, which denotes a hired servant; and as Noah makes use of the word עבד in the curse which he denounces upon Ham and Canaan immediately after the deluge, it would appear that slavery had its origin before that event. If so, it may be plausibly conjectured that it began amongst those violent persons whom our translators have called *giants*,[2] though the original word נפלים literally signifies *assaulters of others*. Those wretches seem to have first seized upon women, whom they forcibly compelled to minister to their pleasures; and from this kind of violence the progress was natural to that by which they enslaved their weaker brethren amongst the men, obliging them to labour for their benefit, without allowing them fee or reward.

Prior to the deluge.

Nimrod enslaved his captives.

After the deluge the first dealer in slaves seems to have been Nimrod. "He began," we are told, "to be a mighty one in the earth, and was a mighty hunter before the Lord." He could not, however, be the first hunter of wild beasts; nor is it probable that his dexterity in the chase, which was then the universal employment, could have been so far superior to that of all his contemporaries, as to entitle him to the appellation of "the mighty hunter before the Lord." Hence most commentators have concluded, that he was a hunter of men; an opinion which they think receives some countenance from the import of his name, the word Nimrod signifying a rebel. Whatever be in this, there can be little doubt that he became a mighty one by violence; for it appears from Scripture, that he invaded the territories of Ashur the son of Shem, who had settled in Shinar; and, obliging him to remove into Assyria, he seized upon Babylon, and made it the capital of the first kingdom in the world. As he had great projects in view, it seems to be in a high degree probable that he made bond-servants of the captives whom he took in his wars, and employed them in building or repairing the metropolis of his kingdom; and hence may perhaps be dated the origin of postdiluvian slavery.

Slavery in the days of Abraham.

That it began thus early can hardly be questioned; for we know that it prevailed universally in the age of Abraham, who was born within seventy years after the death of Nimrod. That patriarch had three hundred and eighteen servants or slaves, born in his own house, and trained to arms, with whom he pursued and conquered the four kings who had taken captive his brother's son.[3] And it appears from the conversation which took place between him and the king of Sodom after the battle, that both believed the conqueror had a right to consider his prisoners as part of his spoil. "Give me," says the king, "the *persons*, and take the *goods* to thyself." It is indeed evident from numberless passages of scripture, that the domestics whom our translators call servants, were in those days universally considered as the most valuable part of their master's property, and classed with his flocks and herds.

---

[1] The Roman orator's definition of slavery, Parad. V. is as accurate as any that we have seen. "Servitus est obedientia fracti animi et abjecti et arbitrio carentis suo;" whether the unhappy person fell into that state with or without his own contract or consent.

[2] Gen. vi. 4.

[3] Gen xiv.

Authorised by the Mosaic law.

That the practice of buying and selling servants thus early begun amongst the patriarchs descended to their posterity, is known to every attentive reader of the Bible. It was expressly authorised by the Jewish law, in which are many directions how such servants were to be treated. They were to be bought only of the heathen; for if an Israelite grew poor and sold himself either to discharge a debt, or to procure the means of subsistence, he was to be treated not as a slave צבר, but as a hired servant שביו, and restored to freedom at the year of Jubilee. Unlimited as the power thus given to the Hebrews over their bond-servants of heathen extraction appears to have been, they were strictly prohibited from acquiring such property by any other means than fair purchase. "He that stealeth a man and selleth him," said their great lawgiver, "shall surely be put to death."[1]

Spread over the whole world.

Whilst slavery, in a mild form, was permitted amongst the people of God, a much worse kind of it prevailed amongst the heathen nations of antiquity. With other abominable customs, the traffic in men quickly spread from Chaldea into Egypt, Arabia, and over all the east, and by degrees found its way into every known region under heaven.

Of this hateful commerce we shall not attempt to trace the progress through every age and country, but shall content ourselves with taking a transient view of it amongst the Greeks and Romans, and a few other nations, in whose customs and manners our readers must be interested.

Slavery amongst the Greeks.

One can hardly read a book of the Iliad or Odyssey, without perceiving that, in the age of Homer, all prisoners of war were liable to be treated as slaves. So universally was this cruel treatment of captives admitted to be the right of the conqueror, that the poet introduces Hector, in the very act of taking a tender and perhaps last farewell of his wife, when it was surely his business to afford her every consolation in his power, telling her, as a thing of course which could not be concealed, that, on the conquest of Troy, she would be compelled

> To bear the victor's hard commands, or bring
> The weight of water from Hyperia's spring..

At that early period, the Phœnicians, and probably the Greeks themselves, had such an established commerce in slaves, that, not satisfied with reducing to bondage their prisoners of war, they scrupled not, for supplying their foreign markets, to kidnap persons who had never kindled their resentment. In the fourteenth book of the Odyssey, Ulysses represents himself as having narrowly escaped a snare of this kind laid for him by a false Phœnician, who had doomed the hero to Lybian slavery; and as the whole narrative, in which this circumstance is told, is an artful fiction, intended to have the appearance of truth to an Ithacan peasant, the practice of kidnapping slaves could not then have appeared incredible to any inhabitant of that island.

Such were the manners of the Greeks in the heroic age; nor were they much improved in this respect at periods of greater refinement. Philip of Macedonia, having conquered the Thebans, not only sold his captives, but even took money for permitting the dead to be buried;[2] and Alexander, who had more generosity than his father, afterwards razed the city of Thebes, and sold the inhabitants, men, women, and children, for slaves.[3] This cruel treatment of a brave people may indeed be supposed to have proceeded, in the first instance, from the avarice of the conqueror; and in the second, from the momentary resentment of a man who was savage and generous by turns, and who had no command of his passions. We shall not positively assign it to other causes; but from the manner in which the Spartans behaved to their slaves, there is little reason to imagine that, had they received from the Thebans the same provocation with Alexander, they would have treated their captives with greater lenity.

Slave among the R mans.

It has been said, that in Athens and Rome slaves were better treated than in Sparta. But in the former city their treatment cannot have been good, or their lives comfortable, when the Athenians relished that tragedy of Euripides in which Hecuba, the wife of Priam, is introduced as lamenting that she was chained like a dog at Agamemnon's gate. Of the estimation in which slaves were held in Rome, we may form a tolerable notion from the well-known fact, that one of those unhappy beings was often chained at the gate of a great man's house, to give admittance to the guests invited to a feast. In the early periods of the commonwealth it was customary, in certain sacred shows exhibited on solemn occasions, to drag through the circus a slave, who had been scourged to death, holding in his hand a fork in the form of a gibbet.[4] But we need not multiply proofs of the cruelty of the Romans to their slaves. If the inhuman combats of the gladiators admit of any apology on account of the martial spirit with which they were thought to inspire the spectators, the conduct of Vedius Pollio must have proceeded from the most wanton and brutal cruelty. This man, who flourished not in the earliest periods of the republic, when the Romans were little better than a savage banditti, but in the polished age of Augustus, frequently threw such slaves as gave him the slightest offence into his fishponds to fatten his lampreys; and yet he was suffered to die in peace. The emperor, indeed, upon coming to the knowledge of his cruelty, ordered his lampreys to be destroyed, and his ponds to be filled up; but we do not recollect that any other punishment was inflicted on the savage master.

Origi Roma Slave

The origin of slavery in Rome was the same as in every other country. Prisoners of war were of course reduced to that state, as if they had been criminals. The dictator Camillus, one of the most accomplished generals of the republic, sold his Etrurian captives to pay the Roman ladies for the jewels which they had presented to Apollo. Fabius, whose cautious conduct saved his country when Hannibal was victorious in Italy, having subdued Tarentum, reduced thirty thousand of the citizens to slavery, and sold them to the highest bidder. Coriolanus, when driven from Rome, and fighting for the Volsci, scrupled not to make slaves of his own countrymen; and Julius Cæsar, among whose faults wanton cruelty has never been reckoned, sold at one time fifty-three thousand captives for slaves. Nor did the slaves in Rome consist only of foreigners taken in war. By one of the laws of the twelve tables, creditors were empowered to seize their insolvent debtors, and keep them in their houses till, by their services or labour, they had discharged the sum they owed. The children of slaves were the property not of the commonwealth, or of their own parents, but of their masters; and thus was slavery perpetuated in the families of such unhappy men as fell into that state, whether through the chance of war or the cruelty of a sordid creditor. The consequence was, that the number of bondmen belonging to the rich patricians was almost incredible. Caius Cæcilius Isidorus, who died about seven years before the Christian era, left to his heirs four thousand one hundred and sixteen slaves; and Augustus once put twenty thousand of his own slaves on board the corn ships.

Its d tion.

Though many laws were enacted by Augustus and other patriotic emperors to diminish the power of creditors over their insolvent debtors; though the influence of the mild spirit of Christianity tended much to meliorate the condition of slaves even under Pagan masters; and though the emperor Hadrian made it capital to kill a slave without a just reason, yet this infamous commerce prevailed universally in the empire for many ages after the conversion of Constantine to the religion of Christ. It was not indeed completely abolished even in the reign of Justinian; and in many countries which had once been provinces of the empire, it continued long after the empire itself had fallen to pieces.

Sl y a- mo t the an t G ans.

Amongst the ancient Germans, it was not uncommon for an ardent gamester to lose his personal liberty by a throw of the dice. This was indeed a strong proof of savage manners; but the general condition of slaves among those barbarians seems to have been much better than among the polished Greeks and Romans. In Germany the slaves were generally attached to the soil, and only employed in tending cattle, and carrying on the business of agriculture; for the menial offices of every great man's house were performed by his wife and children. Such slaves were seldom beaten, or chained, or imprisoned. Sometimes indeed they were killed by their masters in a fit of sudden passion; but none were considered as materials of commerce, except those who had originally been freemen, and lost their freedom by play.

In gland an Scot- la

Such is the account which Tacitus[1] gives of slavery amongst the ancient Germans. The Anglo-Saxons, however, after they were settled in this island, seem not to have carried on that traffic so honourably. By a statute of Alfred the Great,[2] the purchase of a man, a horse, or an ox, without a voucher to warrant the sale, was strictly forbidden. That law was, doubtless, enacted to prevent the stealing of men and cattle; but it shows us that so late as the ninth or tenth century a man, when fairly purchased, was, in England, as much the property of the buyer as the horse on which he rode, or the ox which dragged his plough. In the same country, now so nobly tenacious of freedom and the rights of man, a species of slavery similar to that which prevailed amongst the ancient Germans, subsisted even to the end of the sixteenth century. This appears from a commission issued by Queen Elizabeth in 1574, for inquiring into the lands and goods of all her bond-men, and bond-women, in the counties of Cornwall, Devon, Somerset, and Gloucester, in order to compound with them for their manumission, that they might enjoy their lands and goods as freemen. In Scotland there certainly existed an order of slaves, or bond-men, who tilled the ground, were attached to the soil, and with it were transferable from one proprietor to another, at a period so late as the thirteenth century: but when or how those villeins, as they were usually called, obtained their freedom, is a question not yet completely solved. Colliers and salters were, in the same country, in a state little removed from slavery, till near the end of the eighteenth century, when they were manumitted by the British legislature, and restored to the rights of freemen and citizens. Before that period the sons of colliers could follow no business but that of their fathers; nor were they at liberty to seek employment in any other mines than those to which they were attached by birth, without the consent of the lord of the manor, who, if he had no use for their services himself, transferred them by a written deed to some neighbouring proprietor.

S ery a ngst t Cartha- g ns.

That the savage nations of Africa were at any period of history exempted from this opprobrium of our nature, which spread over all the rest of the world, the enlightened reader will not suppose. It is indeed in that vast country that slavery has in every age appeared in its ugliest form. We have already observed, that about the era of the Trojan war, a commerce in slaves was carried on between Phœnicia and Libya; and the Carthaginians, who were a colony of Phœnicians, and revered the customs, manners, and religion of their parent state, undoubtedly continued the Tyrian traffic in human flesh with the inland tribes of Africa.

Slavery amongst the Numidians

With the ancient state of the other African nations we are but very little acquainted. The Numidians, Mauritanians, Getulians, and Garamantes, are indeed mentioned by the Roman historians, who give us ample details of the battles which they fought in attempting to preserve their national independence; but we have no particular account of their different manners and customs in that age when Rome was disputing with Carthage the sovereignty of the world. All the African states of which we know any thing, were in alliance with one or the other of those rival republics; and as the people of those states appear to have been less enlightened than either the Romans or the Carthaginians, we cannot suppose that they had purer morals, or a greater regard for the sacred rights of man, than the powerful nations by whom they were either protected or oppressed. They would, indeed, insensibly adopt their customs; and the ready market which Marius found for the prisoners taken in the town of Capsa, although Sallust acknowledges[3] that the sale was contrary to the laws of war, shows that slavery was then no strange thing to the Numidians. It seems indeed to have prevailed through all Africa from the very first peopling of that unexplored country; and we doubt if in any age of the world the unhappy negro was absolutely secure of his personal freedom, or even of not being sold to a foreign trader.

Slave-trade with the coast of Guinea.

It has been often said, that the practice of making slaves of the negroes is of a very modern date; that it owes its origin to the incursions of the Portuguese on the western coast of Africa; and that, but for the cunning or cruelty of Europeans, it would not now exist, and would never have existed. It is quite certain, however, that the negroes themselves, like all other savage tribes, have from ancient times enslaved their prisoners; and the establishment of a trade by foreigners in African slaves, may at an early period have tempted them, in some quarters, to make captives expressly for the purpose of selling them. But Christians were not the first tempters. It has been proved, that from the coast of Guinea a great trade in slaves was carried on by the Arabs some hundreds of years before the Portuguese embarked in that traffic. Even the wandering Arabs of the desert, who never had any friendly correspondence with the Christians of Europe, have from time immemorial been served by negro slaves. In all probability, indeed, these tribes have, without interruption, continued the practice of slavery from the days of their great ancestor Ishmael; and it seems evident, that none of the European nations had ever seen a woolly-headed negro till the year 1100, when the crusaders fell in with a small party of them near the town of Hebron in Judæa, and were so struck with the novelty of their appearance, that the army burst into a general fit of laughter.[4] Long before the crusades, however, we know with certainty that the natives of Guinea had been exposed to sale in foreign countries. In 651 the Mohammedan Arabs of Egypt so harassed the king of Nubia or Ethiopia, who was a Christian, that he agreed to send them annually, by way of tribute, a vast number of Nubian or Ethiopian slaves into Egypt. Such a tribute as this at that time, we are told, was more agreeable to the khalif than any other, as the Arabs then made no small account of these slaves.[5]

On the beginning of this commerce, or the dreadful cruelty with which it has been carried on to the present day, it is impossible to reflect without horror; but there is more consolation, however small, in knowing that its original authors were not Europeans. The purchase of Guinea blacks for slaves by foreign nations, commenced ages before the Portuguese had laid that country open to the intercourse of Europe. Even after they had made many incursions into it, the inhabitants were as regularly purchased for slaves by some of the adjoining states, as they were afterwards by the maritime Europeans.

Present state of slavery.

Without prosecuting farther the history of slavery, we pass to the consideration of its present state in the world, and, in particular, the revolutions which have taken place in that worst department of the system which we have been last occupied in examining.

Slavery of white men.

Before describing the altered position now held by negro slavery, it must be remarked that the slavery of white men is by no means yet extinct. Details on this subject will be found in the articles devoted to those countries in which, under various modifications, bondage still prevails; and here a sentence or two must suffice for summing up the result. The nature of that slavery which still prevails among most Asiatic nations, modified in the Mohammedan states by some precepts of their religion, but nowhere entirely extirpated, is familiarly known to most readers, and information regarding it is sufficiently easy of access. The branch of it in which Europeans are most nearly interested, is that atrocious system of piracy which, carried on for centuries by Algiers and the other Barbary states, filled the cities of Northern Africa with Christian prisoners, but has in the present generation been nearly destroyed by the exertions of our own government, aided by the subsequent expeditions of the French. But the snake is scotched only, not killed; and European captives are still said to pine in Morocco, Tunis, and Tripoli. In a preceding paragraph we have considered the villeinage of the dark and middle ages as being a species of slavery. There is no sound reason for regarding it in any other light; and, however far the serf's condition may be superior to that of the slave who belonged to a Roman patrician or a West Indian planter, his servitude is still so utterly repugnant both to humanity and religion, as to make us ashamed of the fact that, in a shape not much improved, it exists still in Christian provinces of northern Europe. The article Russia has described the status of the boors or unfree peasants in that empire; and in more than one kingdom bordering on it, villeinage has never been completely abolished till our own times.

Negro slavery.

But slavery in its most horrible shape, long averted by the spirit of Christianity from those whom Christians were compelled to consider as their fellow-men, has, in regard to the unfortunate people of Africa, been maintained with unrelenting severity by men and nations professing to be disciples of the gospel. The present age has seen the truth mightily triumph in reference to this dark blot of the civilized world; but the evil is not yet entirely eradicated, even where its atrocities have been most decisively condemned; and in several extensive regions of the globe, no acknowledgment of error has yet been extorted.

Negro slavery in North and South America.

Slavery is still lawful over a large part of the American continent. It extends throughout the empire of Brazil, and is general in the southern provinces of the United States. On the declaration of independence, however, seven of the thirteen British provinces which then formed the confederation, abolished slavery absolutely; and the example was followed by two or three of the rest, as well as by several of those afterwards added to the Union. On the whole, including the remnants of bondage in some of the Spanish republics, it has been calculated that the continent of America now contains 4,000,000 of black and coloured slaves. Of these the United States possess about 2,000,000, making about a sixth part of their whole population; but, as the slaves are unequally distributed, they amount in several provinces to half the number of the free whites, and in some places make up a much larger proportion. The French and Spanish colonies in the West Indies, in which likewise slavery remains unabolished, have a slave population amounting to at least 400,000 souls.

Slaver the B coloni

For the British colonies, the exertions of benevolent and enlightened men during the last fifty years, have at length effected a mighty change, the history of which can here be but too briefly told.

Com- mence of effo for ab tion o slave-

1. The Slave Trade. If the merit of originating the great scheme of abolition is to be shared by every one who, either through word or writing, has expressed convictions of the inhuman injustice involved in the slave-trade, or suggested means for its destruction, our list of emancipationists would both be long, and would commence at an early date. But the honour of having planned that systematic co-operation, which alone could effect the end, does clearly belong to the Society of Friends; and in the series of efforts by which that religious body heralded the exertions of our eminent statesmen, the leading part was acted by Anthony Benezet, a French protestant, who, educated in England, became a Quaker and a citizen of Philadelphia; and to William Dillwyn, an American, and a member of the same sect. The former, besides unwearied personal exertions, published, in 1762, the work which first attracted in this country general notice to the slave-trade; the other, visiting England in 1774, opened communications between the American philanthropists and those of our own countrymen who had already engaged in the same cause Among these latter, the foremost place belongs to the honoured name of Granville Sharp.

Granvi Sharp a the sla Somers

This able and excellent man had been induced to interest himself in a class of questions, which arose about the middle of the eighteenth century. West Indian planters, after having brought negro slaves to England, were accustomed to carry them back to the colonies, or even to sell them to others for that destination; and the opinion of eminent lawyers had sanctioned the practice as legal. Instances of crying hardship aroused the sympathy of individuals: Granville Sharp rescued several victims; and, in the year 1772, he obtained a decision of the English judges in the famous case of the negro Somerset, that, as soon as a slave sets his foot on English ground, he becomes free.[1]

Societ the Su pressio the Sla Trade, 1787.

At length, in May 1787, there was instituted in London a Society for the Suppression of the Slave Trade. Besides Dillwyn and Sharp, its most distinguished member was Thomas Clarkson, a young graduate of Cambridge, who, led to study the subject as the theme of an academical essay, had solemnly devoted his life to the cause of negro emancipation. But the Society immediately numbered among its supporters several men of rank and influence; and, among other converts, its founders had gained, even before their organization, William Wilberforce, then member of Parliament for Hull, and afterwards for Yorkshire.

State o public nion.

Although our own days have witnessed a sharp contest in the last stages of those measures, it is not very easy for us to conceive the magnitude of the obstacles which then opposed themselves, even to the most cautious approach towards the subject. Fear of exposure felt by individuals who knew themselves guilty of malpractices, was aided by fear of pecuniary ruin, felt by many who had no other reason for dreading inquiry; and, among the public men of the nation, the corrupt influence of private interests biassed many, while others were influenced by more honest fears for the effects which change might have on the prosperity of the colonies. The Society determined, from the first, to keep the question of slave emancipation studiously in the background. They proclaimed their aim to be, simply, the abolition of the trade in slaves; maintaining, and endeavouring to convince the public, that the slave population of the colonies could be effectually kept up without new importations; and that, indeed, such importation was in itself not only injurious to the real interests of the planters, but eventually pregnant with ruin to the West India Islands as British dependencies. These topics, with others appealing more directly to moral principle and humane feeling, had already been treated in various publications, and they were now anxiously disseminated through the whole of Britain in pamphlets, newspaper articles, and personal communications; while the indefatigable Clarkson travelled everywhere collecting information as to the state of the slave trade.

---

[1] It must be noticed, however, that, a very few years ago, it was decided by Lord Stowell, that slaves who had gained freedom in this way did, on their return to the colonies, become slaves anew.

An excitement was produced which enforced the attention of the government; and its results were still farther aided by the circumstance that Mr. Pitt, who was the intimate friend and political chief of Wilberforce, had already examined the question, and privately declared himself favourable to the views of the society. In February 1788, an order of the crown directed that a committee of the Privy Council should inquire into the state of the slave trade, and its consequences both to Africa, to the colonies, and to the general trade of the kingdom. Before the end of that season, there lay on the table of the House of Commons one hundred and three numerously signed petitions, praying for the abolition of the traffic in human life.

Mr. Wilberforce's ill health detaining him in the country, Mr. Pitt, on the 9th of May 1788, declining to state his own opinion, moved a resolution that the House would, early in the next Session, take into consideration the circumstances of the slave trade complained of in the petitions. This, excepting a motion made by David Hartley some years before, against slavery in the abstract, was the first time the subject had ever been mentioned in the British Legislature. The prayer of the petitions was warmly supported, and delay opposed by Mr. Fox, Mr. Burke, and others. In the meantime, a bill was introduced by Sir William Dolben, and carried through both Houses after virulent opposition, for regulating the burden of the slave-ships, and otherwise diminishing the horrors of the Middle Passage, as it was called, between Africa and the West Indian islands.

On the 12th of May 1789, Wilberforce made his first speech in the House upon the subject, introducing twelve resolutions deduced from the evidence which had been taken before the Privy Council. The propositions, all condemnatory of the trade, were supported by Burke, by Fox, by Granville, and by Pitt, who now declared his opinion unalterable; but the opponents gained their end of delay, by obtaining an order for hearing evidence. It was not till the spring of 1791, that Wilberforce was able to move for leave to bring in a bill, for preventing the further importation of slaves into the colonies in the West Indies. After a stormy debate, the motion was lost by 88 to 163. The enthusiasm of the people, and the favourable dispositions of the legislature, had alike cooled; insurrections of the negroes had broken out in Dominica, the leaders of the French revolution had corresponded with some members of the society, Clarkson had not only visited France, but was the friend of Brissot; and every means had been used for prepossessing the public against the abolitionists.

But the defeated party bated "no jot of hope;" and the public mind became calmer. In April 1792 the House of Commons received from England 330 petitions, and from Scotland 187; and Wilberforce moved an opinion of the House that the slave trade ought to be abolished. He was met by one of the most dangerous enemies of the measure, Mr. Dundas, afterwards Lord Melville, under whose dexterous management an amendment for *gradual* abolition was carried by a large majority; and a few days afterwards the House passed a resolution for abolishing the trade in 1796; but in the House of Lords even this tardy justice was frustrated by a resolution to hear further evidence.

Character of them and their opponents.

In 1793 the House of Commons refused to repeat their resolution of the previous year: in 1795, and each of the four following years, the motion for abolition was made and lost; and the abolitionists then resolved to wait for better times. And thus a measure, calculated to wipe off in part a foul disgrace from the nation,—a measure supported by men of all parties and of all sects,—a measure openly and encouragingly advocated, not only by all the men of highest talent in the country, but by the minister of the day himself, was defeated, after a struggle which, at the time, was aptly called the battle of the pigmies against the giants. Of the sincerity of the other great promoters of the scheme, no doubt has been expressed; but on Mr. Pitt's sincerity there have been thrown very grave suspicions, which it is not possible entirely to dispel. For, although the charge of absolute duplicity is sufficiently rebutted, both by his unbending character and by his admirable speeches on the question, it is unaccountable how he, the most peremptory of all rulers, should not, if he pleased, have forced to silence those subalterns, who trembled to oppose him in any plan but this. The proud son of Chatham loved truth and justice not a little, but he loved power and place greatly more; and he was resolved that negro emancipation should not lose him either a shred of political influence, or a beam of royal favour.

But the triumph was already at hand. The excitement of the war, indeed, still for a time diverted public attention; and, though the principles which had been so convincingly promulgated were silently making converts everywhere, nothing of importance took place for some years, except the appearance of a new and most able advocate in the person of Mr. Stephen, Wilberforce's friend and brother-in-law. In 1804, however, the annual motion of Wilberforce was renewed. The first reading of his Bill for immediate abolition was carried by 124 to 49, the majority containing all the Irish members; and the votes for the third reading were 99 to 33. On the second reading of the Bill in the House of Lords, it was adjourned, without a division, till the following session. In that session, (the spring of 1805,) a new Abolition Bill was thrown out by the House of Commons on the second reading; but, in the same year, a measure of Pitt's for abolishing, by an Order in Council, the slave trade in the newly conquered colonies, which had no charters, was carried into effect without the smallest resistance.

The abolition of the Slave Trade carried, 1807.

The next two years were to witness the final victory. Pitt died; and the ministry of Fox and Lord Grenville was formed. In June 1806, resolutions proposed by the new ministers, pledging the House of Commons to abolition "with all practicable expedition," were carried by more than 100 to 41; and an address to the king, for obtaining the co-operation of foreign powers, was adopted without a division. A bill, founded on the resolutions, was successful in both Houses, and received the royal assent on the 25th of March 1807.

Slave Trade of foreign powers.

The great measure of the British legislature was imitated, in the first instance, by the United States, who were next followed successively by the new South American Republics of Venezuela, Chili, and Buenos Ayres, by Sweden and Denmark, Holland and France. But Spain was brought no farther than to promise in 1814 that she would abolish the slave trade in eight years; while Portugal in 1815 abolished to the north of the equator, promising to abolish finally eight years afterwards, and receiving a sum of money as the price of her acquiescence.

Inefficiency of the Abolition Act; and improvements on it.

In the meantime, the abolitionists in England soon had the disappointment to discover, that the law had no sanction sufficient for enforcing its provisions; whilst the fact, that the horrible trade must now, if conducted at all, be carried on as an act of smuggling, augmented all its miseries, and introduced atrocities not less shocking than those which had prevailed before the passing of Sir William Dolben's carrying act. An energetic remedy was necessary, and such an one was suggested by Mr. Brougham, who, in 1811, introduced a bill, (carried unanimously through both Houses,) declaring the trade in slaves to be felony, and punishable with fourteen years' transportation, or five years' imprisonment. After a time, even this decided measure seemed not decided enough; an act of 1824 made slave-trading a capital offence, by the name of piracy; and the recent acts of 1837, for mitigating the criminal law, have left it punishable with transportation for life. "There is every reason to think," says Lord Brougham, "that no British subjects are now, or have for many years been, directly engaged in this execrable traffic, with the exception of those belonging to the Mauritius. In that island it is certain, that, with the connivance, if not under the direct encouragement, of the higher authorities of the colony, slave-trading to an enormous extent was for some years openly carried on."

Treaties with foreign powers for suppression of the Slave Trade.

The treaties with foreign powers, crippled by national jealousies, were found equally inefficient with our own law. The king of Spain, one of the two great offenders, after having had the meanness to accept, by a treaty of 1817, a large sum from our treasury, as the price of his promise to abolish his slave-trade on the north of the equator immediately, and to put a final stop to the traffic in 1820, had next the effrontery to refuse all performance of the engagement for which he had thus received the consideration; and a vote of abolition, passed by the Cortes in 1822, remained of course inoperative. The great difficulty,—the right of one nation's cruisers to search vessels under the flag of another power, when suspected of slaving,—was however mutually conceded in 1817, between Great Britain on the one hand, and Portugal and Spain (within the limits embraced in the subsisting treaties) on the other; and a similar treaty was effected with Holland in the succeeding year.

Faults and defects of our treaties

But, besides other faults, there were, in our treaties of this sort, two main defects, which, of themselves, rendered the whole system of checks quite inoperative. First, the cruisers, except under our treaty with the Netherlands, had no power to capture vessels not having slaves on board, although it might be fully proved that they were slaving-ships, or even that they had just delivered a cargo. In consequence of this, not only were notorious slavers frequently dismissed after examination, but, in several instances, which have been fully authenticated, the wretches in command were known to throw their slaves overboard on a chase, in the hope of thus removing the only ground on which their detention could be legally justified. Secondly, condemned vessels, instead of being broken up, were sold, and, being fitted for no trade but their own, fell again almost invariably into the hands of the slave-dealers.

New and more effectual treaties since 1830.

In neither of these particulars was any improvement effected till after the late revolution in France, whose subjects, since the restoration, had begun to rank amongst the most active of the contraband slave merchants. In 1833 a treaty was concluded between our government and that of France, by which the breaking up of the vessels was agreed to; and it was also declared, that all vessels ascertained by certain equipments to be intended for the slave trade, might be lawfully detained and confiscated, even though slaves had not been found on board, nor even embarked. France and England have since taken the lead in urging all other Christian powers to accede to these conventions; but as yet their success has been far from general. The five powers with which this country previously had conventions on the subject have come very reluctantly into the additional measures; and one of them, namely, Portugal, has shown a most disgraceful want of faith in fulfilling her engagements. The protection of the Portuguese flag was and is sold by the authorities of that government on the African coast; and miscreants, thus furnished with papers apparently regular, and not having yet received their slave-cargoes, insolently defy our cruisers, or even prosecute our captains for damages, on account of illegal detention. Our government, however, have recently shown a determined front; and we may perhaps hope that the feeble and faithless power which insults us and outrages humanity, will at length suffer condign punishment. As to Spain, between 1823 and 1832, her slavers imported into Cuba 100,000 slaves at least. The equipment clause was always refused by the cabinet at Madrid; and it was not till 1835, after the death of Ferdinand, that our minister at that court was able to extort the accession of the Spanish government to that essential article. The effects of this new treaty have been exceedingly encouraging: within six months after its execution, as many Spanish slavers lay waiting the sentence of our Confiscation Court at Sierra Leone, as had been taken during any three years under the previous conventions. The Brazilian government, although professedly anxious to discourage the importation of new slaves, on account of the danger the whites already incur from an increasing black population, have pleaded, with some plausibility, their want of power to check the trade effectually, so long as the Portuguese flag shall be allowed to protect the slavers. Sweden and the Netherlands were not prevailed on to accede to the French conventions till the year 1838.

Of those powers with which we had previously no agreement, Denmark and the Sardinian States both acceded in 1834. Prussia has shewn a reluctance, for which it is not easy to account. The display of the same spirit by Russia was not so much matter of surprise. Austria, though the emperor has imitated our laws, declaring any slave free who touches Austrian ground, and also making the slave-trade heavily punishable, has acted with its accustomed jealousy, in refusing co-operation with other states. Tuscany and the Two Sicilies joined the league in 1838. With the republics of the New World our negociations have been exceedingly unsuccessful. The United States have peremptorily refused to combine with any foreign power for the suppression of the slave-trade; and, amongst the Spanish commonwealths, Venezuela is the only one which has come cheerfully forward, although the objections started by some of the rest do not seem to be insuperable.

Disa

the
Tra

Altogether, those efforts which philanthropists have so long continued for removing this blot from the name of Christianity, have not yet by any means produced such results as can allow us to believe that the struggle is nearly at an end. Partly through defects in the machinery of the laws and treaties,—partly through dishonesty or lukewarmness in the contracting powers or their officials,—partly through causes which can never be removed while the foul shape of slavery itself darkens any corner of the earth,—the traffic in human blood still goes on with an activity that is incredible to all but those who have studied the subject. The proofs of this lamentable fact are nowhere so convincingly stated as in a work on *The African Slave Trade*, published in 1839, by Mr. Fowell Buxton, from which we can afford to abstract but a very few statements, observing, at the same time, that there is not one of them but is below the truth. According to the highest of those estimates which have been founded on assured data, the Christian slave trade still robs Africa every year of 250,000 human beings. According to the very lowest computation, it absorbs 150,000. To this number must be added that of the Mohammedan trade, which exports at least 50,000 annually; so that we are much below the mark when we assert, that, in the course of every year, 200,000 negroes, at least, are carried off into hopeless slavery. But this is not all. It may be safely asserted, that, for every slave who is exported, there is sacrificed one human life, and perhaps much more. Mr. Buxton's calculation is the following: First, the slaughter of the wars which supply the slaves, the ill-usage of the captives on their march, and their sufferings while detained on the coast, cause together a mortality of 100 per cent. Secondly, the disease and cruelty of the voyage, now worse than ever it was, carries off, at the very least, 25 per cent. Thirdly, the loss after landing in the colonies, and during what planters used to call the "seasoning," amounts to at least 20 per cent. Upon these assumptions, "for every 1000 negroes alive at the end of a year after their deportation, and available to the planter, we have a sacrifice of 1450. Of 150,000 negroes, landed annually in Cuba, Brazil, &c. 30,000 die in the seasoning, leaving 120,000 available to the planter. If 150,000 were landed, there must have been embarked 37,500 more, who perish in the passage; and if 187,500 were embarked, 187,500 more must have been sacrificed in the seizure, march, and detention. It is impossible for any one to reach this result, without suspecting, as well as hoping, that it must be an exaggeration; and yet there are those who think that this is too low an estimate." Putting these facts in another shape, we find, that the slave trade between Africa and America subjects annually to the miseries of permanent bondage, no fewer than 120,000 negroes; whilst, during the same period, it destroys the lives of 255,000 more.

II. Slavery. But, leaving here the consideration of the slave trade, we pass to the history of those measures which, following up its abolition in our own colonies, have destroyed it effectually as to them, by eradicating slavery itself.

Co hence- me of me res for em ipa- tion f the neg slav

Immediately on the passing of the act 1807, there was formed by the abolitionists a new association, which they called "The African Institution." Besides objects connected with the recent measure, and embracing the tasks of watching its execution, of prevailing on foreign powers to imitate our policy, and of aiding in the civilization of Africa, this body gradually began to bestow great attention on the state of slavery in our own colonies, having an especial view to its ultimate abolition, which was afterwards taken up by the Anti-Slavery Society; for their hopes soon waxed very low as to that progressive amelioration in the treatment and even the enlightenment of the slaves, to which some among them had looked forward as one consequence to flow from the stoppage of the foreign supply. The abolitionists were speedily united in the great aim of emancipation; Clarkson renewed his agitation in the provinces; local societies were formed every where, and tracts and larger works were circulated; while in Parliament, Wilberforce, the apostle of the cause, was now seconded by Messrs. Brougham, Mackintosh, Buxton, Lushington, William Smith, and others, in pressing vainly on the House of Commons the adoption of measures tending to prepare the slave for eventually obtaining freedom.

Firs ro. cee s in Par nent for an- cipa n.

At length the trenches were opened in Parliament; and in this new attack, as in the former, the van was led by the Quakers, whose petition for the extinction of slavery was presented by Mr. Wilberforce to the House of Commons in March 1823. Soon afterwards, a motion by Mr. Buxton, for a resolution declaring slavery repugnant both to Christianity and to the British constitution, was defeated by Mr. Canning on counter resolutions, recommending certain necessary reforms. These and other improvements, it was asserted, might be safely left to the colonial legislatures; and the ministry at the same time intimated, that, if the West Indian Assemblies refused to do their duty, it would become necessary for the British Parliament determinedly to interfere.

That no effectual reforms could proceed from the planters themselves, the abolitionists had been long convinced. The government and their supporters, said they, had forgotten two of the prominent features of society in the West Indies; the management of estates by agents for absentee proprietors, and that spirit of reckless adventure which was at once a cause and an effect of West Indian embarrassments. It might have been added, and some had the firmness to add it, that the planters, supposing them ever so well disposed, dared not to introduce any such mitigation of rigour as would afford sufficient protection against individual oppression. The slavery of multitudes was never in any country maintained but by the reign of terror; and, when an enslaved population has reached a certain limit in strength and intelligence, society must inevitably undergo one or another of three changes;—inhumanly increased severity, or universal emancipation, or universal revolution.

Case of the Missionary Smith.

In 1824, Mr. Canning, who, though he had been a zealous abolitionist, acted in regard to the new question a part totally unworthy of him, defeated, by a ministerial majority, Mr. Brougham's very guarded motion of censure on the authorities of Demerara for the infamous and cruel injustice which destroyed the missionary Smith. But the publicity which the debates in Parliament, in this case, gave to the atrocities which, although certainly not common in the colonies or any where upon earth, the colonial laws allowed, when they did occur, to pass with perfect impunity, did more than any thing ever yet had done to excite the indignation of the British people.

New state of public opinion.

The question, in fact, was surprisingly narrowed. When, in 1788, the abolitionists attacked the outworks which flanked the edifice of slavery, the fortress itself was pronounced by its defenders to be absolutely impregnable. The good of the empire, the good of the slave, the principles of all governments, the very Bible itself, were appealed to as authorising the property in human flesh. But now, for many years, no man had breathed any argument of the sort. It was plain that emancipation must come, and that speedily; the parties were only at issue as to the time and the manner. Even the more intelligent among the planters, who saw the negroes swarming around them in hundreds of thousands, and already beginning to think dangerously, (that is, justly,) seem scarcely to have extended their hopes farther than to obtaining liberal compensation for all their losses, present or prospective, certain or conjectural. But the attitude which they chose, almost universally, to assume, was that of defiance towards the mother-country; and, accordingly, the right of the Colonial Assemblies to legislate for their own islands, and the danger which would be incurred by irritating them, were urged alternately with those other topics, of the risk of revolution through hasty changes, the unfitness of the uninstructed negroes to act as freemen, and such other grounds, which now became the arguments of those who wished the British Parliament to decline interfering.

Review of reforms effected in the slave-law of the colonies from 1823 to 1830.

Down to the year 1830, how much had been done, either in the chartered colonies, or in those governed immediately by the crown, for carrying into effect the reforms embodied in the resolutions of 1823, and in the subsequent recommendations of the government?—1. For providing the means of education and religious instruction for the slaves, no one effectual measure had been taken in the colonies of either class. The consolidated slave law for the crown colonies, contained in an Order in Council, dated 8th February 1830, was held out as an improvement on the Trinidad Order in Council of 1824, and was proposed to the chartered colonies as a model for their adoption. It contained no provision for this purpose. 2. The Sunday markets were abolished in the crown colonies by the order of 1830, and they were also abolished by Grenada and Tobago, two of the chartered islands. The other colonies of this class had expressly legalised them. 3. Even this partial abolition was rendered useless, by the total omission of any allowance of equivalent time to the negroes in lieu of Sunday, for marketing or for cultivating their provision grounds. 4. The new order wisely made the evidence of slaves admissable in the crown colonies to the same extent as that of free persons, subject only to remark on the slave's status as affecting credibility. Grenada and Tobago had adopted a similar law; while, in the other colonies of their class, the admission of slave evidence was hampered and restricted so much as to make the grant perfectly useless. 5. In the crown colonies the marriages of slaves were legalized under certain restrictions; in all others such marriages were everywhere exposed to harassing impediments. 6. In the crown colonies the separation of families had been peremptorily provided against, the order, however, being somewhat vague as to the description of persons whom it should embrace. In the chartered colonies the provisions of this kind were universally insufficient. 7. The right of acquiring property was conferred on the slaves in the crown colonies; on those in the others it was also conferred, but under limitations which made the privilege quite illusory. 8. The order in council gave the slaves the right of redeeming themselves and their families, at a fair appraisement, even against the will of the owners; but it imposed, in reference to this grant, several very harsh conditions. The chartered colonies refused unanimously to introduce any such compulsory manumission. 9. The new order most unfortunately omitted that provision in the Trinidad code, which forbade the master to punish the slave corporally more than once in twenty-four hours; but it limited him to twenty-five lashes at a time. This latter enactment was imitated in two or three of the chartered colonies; and in all the rest the old law remained, which allowed the master to inflict thirty-nine lashes at once on any slave, of any age, or of either sex, for any offence, or for none; and the same law allowed him to imprison in the stocks or workhouse as long as he pleased. 10. In the crown colonies there was required a return, as well as a record, of arbitrary punishments inflicted on the slaves on the plantations; but no such check was imposed as to any other classes, such as mechanics or domestics. In the other colonies there was no return, and no adequate record. 11. By the order in council, the flogging of females was abolished; in every one of the chartered colonies it was still permitted and practised. 12. The order forbade, though not in sufficiently explicit terms, the use of the driving-whip in the field. The legislature of the Bahamas did the same thing. The other legislatures retained the old instruments of punishment. 13. Official protectors of the slaves, none of whom could be slave-holders, were appointed in the crown colonies. The chartered colonies all refused to appoint such functionaries; though in some of them the local magistrates (composed of slave-holders) acted in a similar capacity. 14. Another proposed reform was, the providing that no slave-holder should be appointed to any function connected with the administration of the slave-laws. The order in council, though it obeyed this salutary rule in respect to the protector, disregarded it as to his assistants, on whom devolved a great part of his ordinary duty. In the chartered colonies the rule was little attended to, except in the leading appointments made by the crown. 15. It was also proposed that, in cases involving the status of individuals, the legal presumption should be for freedom and against slavery. This rule, adopted in the crown colonies, was also imitated by Tobago and Grenada, but by no other chartered island. 16. For purifying the administration of justice, which called most grievously for amendment, nothing was done in any colony of either class.

Parliamentary proceedings in 1830–31–32.

In July 1830, Mr. Brougham brought forward his motion, that the House should resolve, at the earliest possible period in next session, to take into consideration the state of the slaves, in order to the mitigation and final abolition of slavery, and more especially in order to the amendment of the administration of justice. It was lost by a large majority, in a very thin House. The great changes in the ministry soon came on; and, during the eventful years 1831 and 1832, the subjects of Great Britain and Ireland had their own battles to fight at home, instead of extending aid to foreign dependents. The only steps taken in that period were, the issuing of new orders in council by the Whig ministry in 1831, which proved as ineffectual as those of their predecessors; and the appointment of committees, both in the Lords and Commons, before both of which a large mass of evidence was taken.

Introdu- tion of measur- the abo- tion of very, 18

At length, after the friends of emancipation had repeatedly pressed the ministry to redeem their pledge of bringing forward a government measure, the ministerial proposition was introduced in May 1833, by Mr. Stanley, then secretary for the colonies. The parts of the resolutions on which the emancipationists were most divided were two; first, the plan of an intermediate state, called an apprenticeship, into which the slave was to be received on his manumission, and which, according to the first draft of the measure, was to last for no less than twelve years; secondly, the proposal of compensation to the slave-owners, which, brought forward at first hesitatingly, at last developed itself into a grant of twenty millions sterling. On the principle of compensation most men were agreed; there was guilt, it is true, in the very act upon which the claim was grounded, but the nation was a thousand times guiltier than the planters, and it would have ill become us to make the minor offenders the only sufferers. The amount and application of the grant were matters less certain. On the question of the apprenticeship there was much more room for doubt; and the most consistent opponents of slavery were decidedly against it. Lord Howick, the under secretary for the colonies, threw up his place rather than advocate it; and it was strenuously resisted in the House by him, Mr. Buxton, and Mr. O'Connell, whose opposition, however, was defeated by an overwhelming majority. Among those who advocated the great principle of the resolutions, the most prominent were, besides the members already named, Mr. Buckingham, Dr. Lushington, Admiral Fleming, and Mr. T. B. Macaulay. The opposition, which scarcely amounted to more than exhortations to caution, with insinuations of insurmountable difficulties, was headed temperately and skilfully by Sir Robert Peel, whose most decided supporters were, Sir Richard Vyvyan, Mr. Godson, Mr. W. E. Gladstone, and Mr. Hume. No division was attempted on any question involving the principle.

The resolutions, on being communicated to the House of Lords, where they were carried without a vote, were supported by the Earl of Ripon, Lord Suffield, Earl Grey, and Lord Chancellor Brougham, and cautiously opposed by the Duke of Wellington, the Earl of Harewood, Lord Ellenborough, and Lord Wynford.

A bill was next brought forward, founded on the resolutions. In the discussion on this bill in the Commons, the most important change effected was, the limitation of the apprenticeship to the term of six years for the plantation-negroes, and four for all others. In the House of Lords, the amendments unsuccessfully proposed by the Duke of Wellington were moderate in themselves, and candidly advocated. On the 28th of August 1833, William the Fourth, giving his royal assent to the act, atoned in some measure for the opposition which, in his early days, he, in common with his whole family, except the Duke of Gloucester, had offered to the abolition of the slave trade. William Wilberforce died while the resolutions preparatory to the bill were at their last stage in the House of Commons.

The leading provisions of the great measure for the abolition of slavery were the following.

Summ of the for abo ing sla in the tish do nions.

The act was to take effect on the first day of August 1834, on which day slavery was to cease throughout the British colonies. And, in the first place, all registered slaves, who should at that date be within any of our colonies, and should appear to be six years old and upwards, were to become "apprenticed labourers" to those who had been their owners in slavery; while slaves who had been already brought, or apprenticed labourers who hereafter might be brought, into the United Kingdom, with the consent of their possessors, were to be absolutely free from the date of the act. The apprentices were divided into three classes. The first two classes, called "prædial apprenticed labourers," comprised all slaves "usually employed in agriculture, or in the manufacture of colonial produce," upon the lands in the colonies; the first class being slaves of this sort, who were usually employed on lands belonging to their owners, and who were declared to be "attached to the soil;" the second class, declared to be "not attached to the soil," being such slaves as were similarly employed on lands not belonging to their owners. The third class, called "non-prædial apprenticed labourers," embraced all slaves not included in either of the two other classes. The apprenticeship of the first and second classes was not to continue beyond the first day of August 1840; and such apprentices were not to be liable, in virtue of their apprenticeship, to labour for their employers for more than forty-five hours in any one week. The apprenticeship of the third class was not to continue beyond the first day of August 1838. Voluntary discharges by the employers, before the expiration of these periods, were allowed, under provisions to secure old and infirm apprentices against destitution; and the apprentice was to be entitled to claim his discharge, even against his employer's consent, on payment of the appraised value of his services. No apprentices were to be removed from the colony to which they belonged; and those of the first class were not to be removable even from their own plantation, except that they might be removed to other plantations of the same owner in the same colony, on a certificate of justices of the peace that the removal would not injure their health or welfare, nor separate members of the same family. Under similar restrictions and conditions, the services of the apprentices during their term were to be transferable property. It was conditioned that the employers were to furnish the apprentices with food, clothing, lodging, and other necessaries, according to the existing laws of the several colonies, and to allow them sufficient provision-ground, and time for cultivating it, in cases where that mode of maintenance was adopted. Children born upon or after the first of August 1834, as also all those under six years of age at that date, although they became at once free, might, if proved destitute to the satisfaction of a magistrate, be bound out by the magistrate as apprentice to the employer of the mother, by indenture, to continue in force till the child had completed its twenty-first year. For giving effect to the act, the crown was declared entitled to name, or to authorise governors of colonies to name, justices of the peace by special commission, and to give salaries not exceeding L.300 a-year, to such justices, not exceeding one hundred in all.

The act limited itself to general principles, such as those now specified, declaring that, for carrying the principles into effect, enactments by the several local authorities were the most proper means; and it therefore provided for having such regulations made by the local legislatures for the colonies which had charters, and by the king in council for the crown colonies. It was provided, however, that no such local acts were to authorise the employers, or any one but the special justices, to punish the apprentices by whipping, beating, imprisonment, or addition to the hours of labour; and that they were not to authorise corporal punishment of females on any account, or by sentence of any court. The special justices were made exclusive judges, in the first instance, in all questions between the employer and the apprentices; and no sentence was to impose as punishment extra-work for more than fifteen hours in any week, nor prolongation of apprenticeship, except in the case of runaways, whose prolonged service should not be compellable after the termination of seven years from the end of the apprenticeship. No apprentice was, whether under the act, or by way of punishment, or otherwise, to be compelled to labour on Sundays, except for certain necessary purposes; and none was to be prevented from attending anywhere on Sundays for worship at pleasure.

The remaining sections of the act provided for the raising and application of the twenty millions of compensation-money. The sum might be raised by loans, under the usual restrictions on the government; and commissioners, not fewer than five, were to be appointed by the crown for distributing it, while assistant commissioners were to act for the same purpose in the colonies. No money was to be payable to any slaveholder in any colony, until it should have been declared by an order in council, that satisfactory provision had been made by law in such colony, for giving effect to the act by special or supplementary regulations. The whole money was to be divided into nineteen shares, one for each of the colonies, each share being proportional to the number of registered slaves in the colony, taken in connection with the market-price of slaves in each colony, on an average of eight years ending with 1830.

Proceedings taken under the act.

In virtue of this act, upon the first of August 1834, nearly 800,000 negroes became nominally free; but both the friends and the opponents of emancipation watched with much anxiety what would be their conduct during that probationary state which it had been deemed proper for them to pass through,—a state which, by the very removal of some evils, opened the way for certain others, and which, while it gave increased protection against some kinds of oppression, left the negroes more helpless against severities and neglect of other kinds. Two subsequent acts of Parliament provided as far as possible against abuse; and, although many conflicting accounts have reached this country, there does seem to be no sufficient reason for believing that the treatment of the apprentices was really in any material respect worse than it had been during their slavery; while there appears to be as little reason for doubting, that the slaves in general conducted themselves with thankfulness and decency on their change of condition.

Shortening of the apprenticeship by some colonial legislatures.

But in different islands the policy of the local legislature was very various. Many of the colonists were as well satisfied as the most zealous members of the Anti-Slavery Society, that the apprenticeship was wrong and dangerous. Antigua had the honour of leading the way in making this opinion operative. The legislature of that island declined to take advantage of the apprenticeship at all; its slaves were emancipated at once, and "on Christmas-day 1834, for the first time these thirty years, martial law was not proclaimed in Antigua." Bermuda followed the example, which was next imitated by the small isles, and afterwards by the great island of Barbadoes. Still some colonies held out, with Jamaica at their head; and, particularly from this island, there reached us not only threatening resolutions of the Assembly, but reports of extreme severities towards the slaves, and of decided hostility to the stipendiary magistrates; while one or two of the colonies would not even condescend, for several years, to take such steps as the act declared to be necessary for entitling their landholders to payment of the compensation-money.

In the spring of 1838, the question of immediate abolition of the apprenticeship was stirred, on those and other grounds, in both Houses of Parliament. Lord Brougham's motion to this effect, supported by Lord Lyndhurst and others, was met by the previous question. Sir George Strickland's, in the House of Commons, was also negatived; and, although a similar resolution was afterwards carried in the Commons, the ministry intimated that they would throw every obstacle in the way of any measure founded on it, and the attempt was therefore given up.

Final and complete emancipation of the negroes, 1838.

But the colonists were warned in time, by the spirit which reigned here, and by that which appears to have been rising among the negroes. They proceeded forthwith to abolition; and, on the first of August 1838, there was not a slave left in any British colony, except the Mauritius alone, in which instructions from the home government have since carried the enfranchisement into effect. The act of the Assembly of Jamaica for putting an end to the apprenticeship was accompanied by a protest, which, in its tone of mingled sullenness and pertness, is assuredly the strangest document that ever emanated from any legislative body.

Of the results of this mighty change, we are not yet in a condition to speak. From Jamaica the accounts have been of various complexions; from the other islands almost universally favourable. The negroes have scarcely anywhere shown a disinclination to work, except during the few weeks immediately succeeding their complete manumission; and we look forward with a confident hope to improvement both of society and statistics, believing firmly that the planters have now fairer prospects before them than they have enjoyed at any time during the last half century. If the event shall be otherwise, justice has at least been done; and some atonement has been made for the most heinous crime which our nation ever committed. Nay more, a revolution has been averted, which, before many generations, would assuredly have repeated in our Caribbean Islands all the horrors of Saint Domingo. (B. L.)

Of the Twenty Millions voted by Parliament as compensation to the owners of slaves, the following Table shews the proportions assigned to each colony by the Commissioners appointed by the Act for the Abolition of Slavery, with the value and numbers of slaves in each.

COLONY.	Average Value of a Slave from 1822 to 1830.			Number of Slaves by the last registration in this country.	Relative Value of the Slaves.			Proportion of the L.20,000,000, to which the colony is entitled.

SLEAFORD, a town in the hundred of Fleswell, part of Kesleven of the county of Lincoln, 116 miles from London. It was once the residence of the bishops of Lincoln. It has a fine ancient Gothic church, adorned with many monuments. It has a good market on Fridays. The inhabitants were, in 1801, 1596; in 1811, 1904; in 1821, 2220; and in 1831, 2587.

SLEBEZE, a small island in the straits of Sunda. Long. 105. 24. E. Lat. 5. 54. S.

SLEDGE, a kind of carriage without wheels, for the conveyance of weighty things, as stones, bells, and the like. The sledge for carrying criminals, condemned for high treason, to execution, is called a hurdle. The Dutch have a kind of sledge on which they can carry a vessel of any burden by land. It consists of a plank of the length of the keel of a moderate ship, raised a little behind, and hollow in the middle; so that the sides go a little aslope, and are furnished with holes to receive pins. The rest is quite even.

SLEDGE is a large smith's hammer, to be used with both hands. Of this there are two sorts, the up-hand sledge, which is used by under workmen, when the work is not of the largest sort. The other, which is called the about-sledge, and which is used for battering or drawing out the largest work, is held by the handle with both hands, and swung round over their heads, at their arm's end, to strike as hard a blow as they can.

SLEEP, that state of the body, in which, though the vital functions continue, the senses are not affected by the ordinary impressions of external objects. See DREAMS, PHYSIOLOGY, and SOMNAMBULISM.

SLEEPERS, in *Natural History*, a name given to those animals which sleep all winter, such as bears, marmots, dormice, bats, hedgehogs, swallows, and the like. These do not feed in winter, have no sensible evacuations, breathe little or none at all, and most of the viscera cease from their functions. Some of these animals seem to be dead, and others return to a state like that of the fœtus before birth. In this state they continue, till, by an increase of heat, the animal is restored to its former functions.

SLEIDAN, JOHN, an excellent German historian, born of obscure parents, in 1506, at Sleidan, a small town on the confines of the duchy of Juliers. After studying some time in his own country, together with his townsman, the learned John Sturmius, he went to France, and in

---

* Deficient fractions.

1525 entered into the service of the cardinal and archbishop John du Bellay. He retired to Strasburg in 1542, where he acquired the esteem and friendship of the most considerable persons, particularly of James Sturmius, by whose advice and assistance he was enabled to write the history of his own time. He was employed in some public negociations; but the death of his wife, in 1555, plunged him into so deep a melancholy, that he entirely lost his memory, and died the year following. In 1555 came out, in folio, *De Statu Religionis et Reipublicæ sub Carolo Quinto*, in fifteen books, from the year 1517, when Luther began to preach, to the year of its publication, and this history was presently translated into most of the languages of Europe. Besides this great work, he wrote, *De quatuor summis Imperiis, libri tres;* with some other historical and political pieces.

SLESWICK, or SCHLESWIG, a province in the kingdom of Denmark, in that division usually denominated the Duchies, including, with this province, Holstein and Lauenberg, all of which are inhabited by people of German origin, who speak that language, and are regulated by different laws from the rest of Denmark. This province is bounded on the north by Jutland; on the north-east by the Little Belt, wherein the Island of Aroe, which is a part of it, lies; on the east by the Baltic sea, wherein are the Islands Alsen and Femern; on the south by Holstein, from which it is divided by the river Eyder and the Sleswick canal; and on the west by the German Ocean, in which are the islands of Nordstrand, Pellworm, and some other smaller ones. The whole extent is 3515 square miles. It comprehends thirteen cities, fourteen market-towns, and 1500 hamlets or villages, divided into 257 parishes, which contained 36,000 inhabitants in 1832. It is in general a level district, having on the western side many tracts of rich meadow land; while, on the eastern side, its agricultural produce are corn, butter, cheese, and meal; but through the middle of the province runs a ridge of sandy hills, which scarcely repay the cost of cultivation. There are many lakes and marshes, and on the eastern side, fiorden or bays, formed by projecting woody headlands, which have a picturesque appearance. The climate is cold in winter, but remarkably variable. There are few manufactures, and the trade chiefly consists of the export of the products of the soil. or of the fisheries; which last forms an important part of the occupation of a great number of the inhabitants. The principal towns, besides the capital, are Hadersleben, Apenrade, Tondern, Bredsted, Husum, Nordstrand, Toning, Fredrichstadt, Flensburg, and Eckenfiorde.

SLESWICK, a city, the capital of the province of that name in the continental dominions of Denmark. It stands on an arm of the sea on the German Ocean, and the buildings are erected in the form of a crescent. It is an open town, most irregularly built, and is divided into four distinct parts. It is the seat of a Lutheran bishop, has a domkirche or cathedral, and four other churches, and several collegiate institutions for education. The harbour has only nine feet water, and is of small extent. The trade is inconsiderable. There are sugar refineries, tanneries, distilleries, and breweries, all for the home consumption. It contains 1320 houses, with 10,640 inhabitants. Lat. 54. 31. 15. Long. 9. 29. 25. E.

SLEUT-HOUND, the ancient Scots name of the bloodhound. The word is derived from the Saxon *slot*, the impression that a deer leaves of its foot in the mire, and *hound*, a dog; so they derive their name from following the track.

SLICH, in *Metallurgy*, the ore of any metal, particularly of gold, when it has been pounded and prepared for further working.

The manner of preparing the slich at Chremnitz in Hungary, is this. They lay a foundation of wood three yards deep; upon this they place the ore, and over this there are twenty-four beams, armed at their bottoms with iron; these, by a continual motion, beat and grind the ore, till it is reduced to powder. During this operation, the ore is covered with water. There are four wheels used to move these beams, each wheel moving six; and the water, as it runs off, carrying some of the metalline particles with it, is received into several basons, one placed behind another; and finally, after having passed through them all, and deposited some sediment in each, it is let off into a very large pit, almost half an acre in extent; in which it is suffered to stand as long as to deposit all its sediment, of whatever kind, and after this is let out. This work is carried on day and night, and the ore is taken away and replaced by more as often as occasion requires. That ore which lies next the beams, by which it was pounded, is always the cleanest or richest.

When the slich is washed as much as they can, a hundred weight of it usually contains about an ounce, or perhaps but half an ounce of metal, which is not all gold; for there is always a mixture of gold and silver, but the gold is in a larger quantity, and is usually two-thirds of the mixture. They then put the slich into a furnace with some limestone, and slacken, or the scoria of former meltings, and run them together. The first melting produces a substance called *lech*, which they burn with charcoal, to make it lighter, to open its body, and render it porous, after which it is called *rost;* to this they add sand in such quantity as they find necessary, and then melt it over again.

At Chremnitz many other methods are practised of reducing gold from its ore, but particularly one, in which they employ no lead during the whole operation: whereas, in general, lead is always necessary, after the before-mentioned processes.

SLICKENBURG, a small island near the north-west coast of Borneo. Long. 112. 31. E. Lat. 3. 59. N.

SLIDING-RULE, a mathematical instrument, serving to work questions in gauging, measuring, and the like, without the use of compasses; merely by the sliding of the parts of the instrument one by another, the lines and divisions of which give the answer by inspection. This instrument is variously contrived and applied by various authors, particularly Everard, Coggeshall, Gunter, Hunt, and Partridge; but the most common and useful are those of Everard and Coggeshall.

SLIGO, a maritime county in the province of Connaught in Ireland, is bounded on the north by the Atlantic Ocean, on the east by Leitrim, on the south-east by Roscommon, and on the south and west by Mayo. It extends from 53° 54′ to 54° 28′ north latitude, and from 8° 10′ to 9° 10′ west longitude; being thirty-eight miles in its greatest length from north to south, between Mullaghmore Head and Lough Gara, and forty-one in breadth from west to east, between Ardmaree and the junction of the three counties of Sligo, Roscommon, and Leitrim, and comprehending an area of 461,753 acres, or 721 square miles.

According to Ptolemy the geographer, this district was inhabited by the tribe of the Nagnatæ, whose chief city, Nagnata, is supposed to have been situated somewhere in the vicinity of the town of Sligo. It afterwards formed part of the kingdom of Connaught, one of the five into which the island was divided previously to the arrival of the English, in the reign of Henry II. It was afterwards possessed by one of the family of the O'Conors, kings of Connaught, who was called O'Conor Sligo, to distinguish him from the other chieftains of the same family; and under him the heads of the septs of O'Bean, O'Doud, O'Gara, O'Hara, M'Donogh, and M'Firbis, were subordinate chieftains in their respective districts. After a protracted struggle between the natives and the English, it fell into the hands of the De Burgos, who, either by force or treaties, had made themselves masters of the greater part of the ancient kingdom of Connaught. When the province was made shire-ground by Elizabeth, in 1569, Sligo formed one of the seven counties into which it was divided; but so far from being thus rendered amenable to the jurisdiction of that queen, it became the theatre of several conflicts in the war against O'Heil, chieftain of Tyrone, in the latter part of her reign. The most remarkable of these was that with Sir Conyers Clifford, who, in attempting to pass into the county from Roscommon with a body of from 1500 to 2000 men, in order to relieve Belleek, was attacked in a defile of the Curlew mountains by O'Roark, chieftain of Breffney, was himself killed, and his troops were driven back with considerable loss. During the civil wars of 1641, the Irish kept possession of the open country until nearly its close, when they were reduced to submission by the parliamentary forces under Ireton. In the subsequent war of 1688, the county was held by the forces of King James for some time, but ultimately yielded to the victorious arms of William III. The French force which landed at Killalla under General Humbert in 1798, had a severe skirmish at Colooney with the Limerick militia, commanded by Colonel Vereker, which ended in the retreat of the latter.

The county includes an extensive line of sea-coast along its northern border, in which are the bays of Classyvaun and Milkhaven in the north, and Brown Bay, which branches into the smaller and less frequented indentations of Drumcliff, Sligo, and Ballysadare Bays. Killalla Bay, to the west of the county, belongs also to Mayo. The island of Innismurray lies about five miles off the northern coast, being separated from the mainland by a passage dangerous, except in moderate weather, from the number of reefs under water. The island itself rises precipitously on the ocean side, but shelves gradually downwards on that of the land: there is but one practicable landing-place. The whole surface extends over 209 acres, of which about 120 are arable, affording pasturage to a few cattle and sheep. There is also a large extent of bog. The inhabitants depend chiefly on the fishery, which in most seasons is abundant. The place is peculiarly remarkable for a small chapel or cell, celebrated for an image of its patron, St. Molasse. Near the chapel is a singular relic, called the cursing-stone, so named from a superstitious opinion of its efficacy in punishing guilt if appealed to according to an established form. The island is also a favourite burial-place: males and females are interred in separate cemeteries.

Mountains.

The land rises into mountains of considerable height in its northern extremity. The principal of these are Benbulben, 1722 feet high; King's mountain, 1527; Cullogherboy, 1430; and Truskmore, part of which is in Leitrim, 2072. In the west are the ranges of the Slieve, Gamph, and Ox mountains, the highest points of which are 1321 and 1446 feet respectively. In the east Kisheorrin and Carriskea rise to the heights of 1183 and 1062 feet. The Curlew mountains in the south-east, between Roscommon and Sligo, only rise to the height of 863 feet. The entire surface of the county contains 449,013 acres of land, of which about 272,000 are capable of cultivation, and the remainder mountain or waste, and 12,740 acres under water. The principal rivers are the Moy, which forms the western boundary, separating the county from Mayo, and emptying itself into Killalla Bay; it is navigable to Ballina, six miles inland, for vessels of ten feet draught; the Tinned, the Easkey, the Ballybeg, the Dunneill, the Ballysadare river, with its branches the Owenmore, Owenbeg, and Arrow, or Unshin, and the Garvogue, a short but rapid stream, rising in Lough Gill, and passing through Sligo town into the bay of the same name. All these rivers have their sources within the county. The lakes are numerous, and several of them large ard highly picturesque. Lough Gill, the most northern, spreads over 3130 acres, besides a small portion in Leitrim; its western side is richly planted, and in it are ten islands, the largest of which are Church Island, 41 acres, and Cottage Island, 13. Lough Arrow, in the east, 3010 acres, is of very irregular form, and contains the islands of Annagowla, 34 acres, Muck, 21, and Inish, 20; Lough Gara, in the south-east, 3683 acres, contains the islands of Derrymore, 33 acres, Inchmore, 21, and the smaller islands of Inch, Inchbeg, Eagle, Crow, and Derrynatallan. Lough Talt, in a basin of the Ox mountains, surrounded by projecting cliffs, 300 acres, and 455 feet above sea level, is remarkable for its abundance of trout, which vary in shape and flavour in various parts of the lake. Lough Easkey, 337 acres, lies in the same mountain range; Templehouse lake contains 356 acres, Cloonacleigha, 177. Smaller lakes are numerous in all parts.

Geolog

The carboniferous, or mountain limestone, including the lower limestone, calp or black shale series, and the upper limestone, forms the basis of by much the greater portion of the county. A small tract of the yellow sandstone and conglomerate shews itself in the extreme north, as also on the north and east of Lough Gara, whence it penetrates, extending into Mayo. The old red sandstone, and sandstone conglomerate, appears in two masses near Lough Arrow, the southern and larger portion plunging deeply into the adjoining county of Leitrim. A very small portion of the granite formation, which lies between Lough Conn and Foxford, enters the county, giving place to a broad belt of trap porphyry, bounded by a narrow fringe of old red sandstone, and stretching in a north-eastern direction, along the line of the Ox mountains to Ballysadare Bay; a mass of granite protrudes through the middle of this formation. To the south of the same bay, and west of Ballysadare town, is a small field of quartz rock. The sandstone in some tracts assumes an appearance which gave rise to the opinion that coal existed under it, but, on making the experiment, the hopes of the speculator were always baffled. Iron was procured in large quantities, particularly at the base of the Ox mountains, until the timber used as fuel for smelting was exhasted. Sulphate of copper and iron pyrites are frequently found in small pieces; and pure copper occasionally in the beds of some of the rivers. Manganese has also been found in various places, and amethysts of large size near Ballymote.

Climat

The climate, owing to the proximity of the sea and the lofty tracts of mountains with which the county is intersected, is moist, and the weather extremely variable, the atmospheric changes being so frequent and sudden, as often to render the barometer an unsatisfactory test of the weather. The soil, in the mountainous districts, is a light sandy loam on a freestone bottom, interrupted by large patches of bog, and often overspread with a thin coat of turf mould. In the low country it is rich and deep, resting on a substratum of limestone, and suitable to the growth of every kind of agricultural produce. In many parts a superior stratum, called by the people lac-leigh, or the grey flag, is found incumbent on the limestone bottom. It is principally composed of silicious marl, in a state so compact, as to be impenetrable to water; thus, by preventing the drainage of the surface, opposing what was for some time deemed an insurmountable obstacle to the successful culture of the land. But it was afterwards discovered, that deep trenching, so as to cut through the adhesive layer, not only served to carry off the water effectually, which now passed freely through the subjacent limestone gravel, but to add to the fertility of the soil; the marl, when broken up and mixed with the surface mould, proving a valuable compost. Timber was abundant, until destroyed by the consumption of it required for the iron works, and by its lavish use for domestic and agricultural purposes, without any regard to the formation of a fresh supply. That the land is capable of furnishing plenty of this valuable article, is evident from the manner in which young forest trees of various kinds shoot up in the mountainous districts, and in the escars which traverse the county in various directions, checked in their growth only by want of due care to protect the young shoots from the depredations of cattle. But this defect in the picturesque and agricultural character of the surface is daily diminishing. The attention of the principal landholders is now particularly directed to the increase of forest timber, and numerous plantations are to be seen round the mansions and villas of the gentry, particularly on the borders of the beautiful lakes which grace the landscape. The prevalence of western gales from the Atlantic forbids the full growth of any trees near the shore, éxcept the willow and sycamore, which are observed to incline in the direction of the prevailing blast. Arbutus of small size grows freely in most parts, as does the myrtle in more favoured aspects. Many parts of the beach along the sea-shore is covered with a coraline sand, interspersed with numerous beds of oyster-shells of considerable extent. These beds are also found in some parts of the interior, at elevations of more than fifty feet above high water mark.

Pola- tio

The population, like that of every other county in Ireland, has been steadily on the increase, ever since the observations of statistical writers have been directed to this subject. The numbers of inhabitants at several periods, are as follows:

Year.	Authority.	No.
1760	De Burgo	38,736
1792	Beaufort	60,000
1812	Parliamentary census	119,265
1821	ditto	146,229
1831	ditto	171,508

According to the last of these results, the population is to the acreable extent of the cultivated land, as one to 1.585 acres, and to that of the total landed surface, as one to 2.693; or, in other words, there is one inhabitant to every acre and a-half in the first case, and to every two acres and a-half in the second. The census taken by the commissioners of Public Instruction in 1834, being arranged in dioceses instead of counties, cannot be depended on as strictly accurate. According to it, the population may be estimated at 174,400, of which number 17,900 were Protestants, and 156,500 Roman Catholics; the former being to the latter as one to nine nearly. The number of presbyterians and other dissenters, who are included in the preceding statement of numbers among the protestants, amounts only to 560. The number of children receiving instruction in public schools, was as follows, according to the returns made under the Population act in 1821, the Commission of Education in 1824–6, the Commission of Public Instruction in 1834, and the Report of the Commissioners of National Education in 1839:

	Males.	Females.	Sex not ascertained.	Total.
1821	5849	3010	—	8,859
1824–6	6516	3686	221	10,432
1834	8562	5259	—	13,821
1838	1551	1102	—	2,653

In the return of 1824–6, the only one in which the difference of religious persuasion is noted, the numbers of each of these are, of the Established Church, 2558; Protestant dissenters, 200; and Roman Catholics, 7495; the religion of the remaining one hundred and eighty not having been ascertained. Of the total number of schools, two hundred and twenty-six, included in the same return, one hundred and thirty were pay-schools, in which the teachers were remunerated by the pupils' fees, seventy-four were supported, either wholly or partially, by voluntary subscriptions, and but twenty-two by grants of public money.

Divisions.

The county is divided into the six baronies of Carbery, Coolavin, Corran, Leney, Tiraghrill, and Tyreragh, which are subdivided into thirty-nine parishes: of these, twenty-three are in the diocese of Tuam, and sixteen in that of Elphin. The county was represented in the Irish Parliament by four members; two for the county and two for the borough of Sligo. By the act of Union, the number was reduced to three, one being deducted from the borough. The Reform act made no change in this respect. The constituency of the county, as registered under the same act at different periods, together with the numbers under the previous act of 1829, by which the forty-shilling constituency had been abolished, was as follows:

	£50.	£20.	£10.	Total.
1831	399	315	299	1013
1832	168	151	370	695
1834	—	—	—	804
1837	273	220	546	1039

According to the last specified return, the number of electors is to the total population as one to one hundred and fifty, and to the number of heads of families as one to twenty-five. The county is in the Connaught circuit; the assizes, and some of the sessions of the peace, are held in the town of Sligo, which contains the county court-house and prison. Sessions of the peace are also held at Ballymote and Easkey, where there are likewise court-houses and bridewells. The county infirmary, and four hospitals are in the first-named town. The lunatic asylum is in Ballynasloe, but several of the unhappy creatures, for whose protection and recovery it was designed, are still kept in the county jail. There are nine dispensaries in various places.

Agriculture.

Most parts of the county afford ample scope for agricultural improvements, either in tillage or pasturage. Oats and potatoes are the principal crops on the tillage land. The culture of wheat was long unknown, the coldness and humidity of the climate having been deemed insuperable bars to its successful treatment, but it is now raised in considerable quantities on the rich lowlands. Green crops, under the rotation system, are also more and more attended to every year. Ploughing is usually effected by two horses, and, in some light soils, two asses are substituted for them; oxen are never used for this purpose. The spade, in many of the mountain districts, still supplies the place of the plough. Fences of every kind are usually constructed; those of dry stones being most common, particularly in the more elevated districts, where the farmers adopt this mode of structure as well to clear their fields of surface stones, as to secure them from trespass. Sea-weed, collected on the shore, which, some years ago, had been manufactured into kelp, is now used as manure, and is in such repute, that it is carried twenty miles up the country. The beds of oyster shells and the coraline sand on some stretches of the beach, are applied to the same purpose. Tillage farms are from five acres, and even lower, to two hundred or three hundred in size. Those used chiefly for pasturage are often of much greater extent, and, until lately, were mostly held by a number of tenants in a species of partnership, according to which, each had an exclusive portion of tillage ground, while a large tract of mountain or coarse bottom-land was depastured in common; but this system has been for several years so much discouraged as to be nearly if not altogether obsolete. The average rent of land is ten shillings and eightpence per acre. Though the tillage system, as stated, is much encouraged and rapidly extending, it is still subordinate to that of pasturage, which is adopted in all parts of the county, and on every description of soil. Horned cattle of the largest size are fattened in the rich lowland plains; young cattle are reared in the hilly and mountain districts; sheep also are kept in large flocks, particularly in the western baronies. Much butter is made, both in dairy farms and by small landholders. Swine, which are reared in great numbers, are looked upon as a very profitable source of income. Goats are not common. The native breed of horses has little to recommend it, unless when improved by crosses from those of the neighbouring counties, in which more attention is paid to them. The maritime situation of the county is well adapted for increasing the quantity of human nutriment, in addition to that derived from agriculture. The bays abound with both round and flat fish. The herring visits the coast in large shoals, and the sun-fish and some species of whales are frequently seen in the offing. But this source of profitable industry is far from being rendered as productive as the natural capabilities of the place would lead us to infer. The want of capital paralyzes the exertions of the fisherman. As long as the boatmen were enabled to procure materials for the making and reparing of their craft, and for the purchase of the necessary fishing gear by the aid of bounties and loans, the occupation was profitable, and the numbers engaged in it increased annually, but since the withdrawing of those encouragements in 1830, the fisheries have retrograded, both as to numbers of men, and as to rate of profit. Of the larger fish, cod, hake, haddock, skate, and turbot, are the most abundant. Sprats are taken in great quantities. The Lissadill oyster is so much esteemed, that there is a regular demand for it in Dublin and other large towns. This fish, with many others of the shell kind, as lobsters, crabs, scallops, &c., are found in many other parts of the coast. There are large and profitable salmon fisheries at Ballina, Sligo, and Ballysadare; and the numerous lakes and rivers supply the usual species of fresh water fish in equal abundance. The increase of agricultural improvement of late years is mainly attributable to the facilities for export afforded by the ports of Sligo and Ballina, but more especially the former, it being the great mart of commerce for the whole county, except its western districts, which, for the same purpose, take advantage of their vicinity to the latter. The statements relative to the external trade will be found in the subsequent description of the town and port of Sligo. The inland trade, in consequence of the want of communication by inland navigation or railroads, is confined to that of coarse cloths, woollens, and stockings from Connaught, and to the sale of linen, mostly for domestic use. The chief trade of this description is from Sligo town to Boyle in Roscommon, and thence, by the Shannon and the two canals, to more distant counties. A more confined traffic is carried on with Colooney. Among the late plans for stimulating national industry by inward channels of communication, it is proposed to carry a railroad from Sligo through Ballysadare, Colooney, and Drumsna to Longford, thence to be divided into two branches; 1st, by Granard, to join the proposed main railroad from Dublin to Enniskillen at Kells in Meath; 2d, through Mullingar, to join the proposed south-western railroad from Dublin to Kilkenny at Celbridge. No measures have been yet adopted to effect this plan.

Manufactures.

The linen manufacture was introduced into the county so lately as the middle of the last century, when a number of weavers were located at Ballymote by Lord Shelburne. It continued to flourish for many years, but at length suffered, as in other parts, by the depression of the trade, and by the introduction of that of cotton; it is now reviving. Coarse woollens are made for domestic consumption. In the neighbourhood of the larger towns are several thriving tanneries, distilleries, and breweries; and the manufacture of flour has caused the erection of numerous mills, which prepare large quantities of grain, both for home consumption and export. The manufacture of kelp is nearly extinct.

There is a considerable number of resident gentry in the county in proportion to its size, and consequently many elegant mansions and well planted demesnes, which contribute more and more every year to diminish the former denuded appearance of the landscape, arising from the improvident destruction of its ancient timber. The houses of the smaller farmers are plain, but comfortable; but the cottages of the peasantry generally present indications of poverty. They are either of stone or mud, rudely thatched with straw or rushes. The food of the labouring classes are potatoes and oaten bread, with some milk and fish, and meat on extraordinary occasions. Fuel from the bogs is abundant. Coal, imported from Great Britain by the vessels which take in return cargoes of agricultural produce, is used in the larger towns, and by the respectable families in their vicinity; but the high price precludes its general use throughout the county. The garments of the men are chiefly of home-manufactured wool, and so were those of the women until lately, when the native fabrics have been nearly supplanted by cheap cottons. Irish is scarcely spoken, except in some of the retired mountain tracts. Early marriages are much encouraged: they generally take place in the winter and spring. The rustic customs and amusements resemble those of the other north-western counties, in which the language and habits introduced from Scotland are less prevalent than in the eastern parts of Ulster.

Antiquities.

There are numerous relics of ancient structures. A round tower at Drumcliff, in Carbery barony, differs from all others in Ireland, in being of smaller size, and inferior architecture. Near the church where it stands, are two stone crosses. On Knocknaree mountains are several cairns; and in the same mountains, a deep valley, thickly planted and watered by several romantic falls, appears to have been formed by a violent organic shock, causing a fissure through the mountain. Some grottoes, hollowed out of the side of a hill near Carron, are of unknown antiquity. Near Sligo town is a cromlech, and a number of circular structures, popularly called giants' graves. Near Castleconnor, in Tyreragh barony, are several vaults of a square form, whether built for cemeteries or storehouses, is uncertain. There are several remains of ancient castles. That of Knocknamoyle, crowning an elevated hill near Skreen, is supposed to have existed before the arrival of the English; the others are thought to have been built since. Upwards of forty monastic buildings are noticed by antiquaries, the ruins of ten of which are still visible; eight others have been converted into parochial churches, but the remainder are known only by name, even the site of some of them being either doubtful or undiscoverable. Close to the ruins of an ancient chapel on Church Island, in Lough Gill, is a kind of chamber, or cavity, called the "lady's bed," to which is attached the superstitious notion, that women who have lain in it will be preserved from the risk of death in child-bed. A well called Tubber-art, in Kilmacteige parish, has the character of performing cures in diseases that have set at defiance the ordinary resources of medicine.

Sligo, the assize town of the county, became a place of importance by the building of a castle there, by the earl of Kildare, soon after the English settlement: its consequence was increased by the subsequent foundation of a Dominican monastery; but its progress was subsequently much impeded by fires, and by the hostilities produced by the struggles for superiority between the English and the natives. It was incorporated and invested with the privileges of a parliamentary borough in 1613, and in 1621 obtained a charter of the staple. In the early period of the war of 1641, it was taken by the parliamentarians, under Sir Charles Coote, but after some time evacuated by them, and thence continued in the possession of the royalists till the termination of the war. In 1688 it declared in favour of King James, was taken for King William by the Enniskilleners, who, in turn, were driven out by General Sarsfield; but the place ultimately surrendered to the earl of Granard. The town is situated on both sides of the mouth of the Garvogue, where it discharges itself into the bay. The river is crossed by two bridges. The streets are narrow, winding, and irregularly built. Its public buildings are, two protestant churches, a Roman Catholic chapel, a Dominican friary, Presbyterian, Independent, and Methodist meeting-houses. The existing remains of the ancient monastery of Sligo still exhibit a fine specimen of the architecture of the period in which it was erected. Near its high altar is the tomb of the O'Conor Sligo, embellished with effigies. The town contains the county infirmary and fever hospital, two dispensaries, cavalry barracks for a hundred men, a library, and a small theatre. There is a mendicity association, which has been for some time in existence, but will shortly be closed, as Sligo is selected for the site of the workhouse for a union that extends over the whole county, except a few detached parts on its borders that are annexed to unions in the adjacent counties. The town is divided, under the poor law act, into three wards, with two guardians to each; the rest of the union being divided into twenty wards, with thirty-three guardians. The markets, which are held daily, the principal being on Thursday and Saturday, are well supplied with grain, meat, fish, and vegetables. Fairs are held five times in the year. The town is a chief station for the constabulary, and for the coast-guard. The paving, lighting, and other departments of the municipal police, are under the direction of commissioners, appointed by several acts of parliament; their jurisdiction extends a mile in every direction from the market cross. Previously to the union, the borough returned two members to parliament; subsequently the number was reduced to one, the right of franchise being vested in the mayor and twenty-seven burgesses and freemen, till the passing of the reform act, when it was extended to the L.10 householders. The number of electors in 1832 was 418; and in 1834, 694. The assizes and sessions of the peace for the county are held here in the court-house, an elegant modern building, and petty sessions are likewise held weekly. The county prison is commodious, well arranged, and under a good system of discipline. It has a tread-mill.

Sligo bay, in its more extended bearings, stretches from Rinoran to Gessige point, at its opening, a distance of about six miles, and is divided into three branches, the central, largest, and deepest of which terminates at the town of Sligo. The entrance of this branch is screened from the violence of the ocean waves by two small islands, Oyster island and Coney island. There are three lighthouses at the mouth of the harbour. Across its main entrance is a bar, with but ten feet depth at low water. Though the entrance of ships of deep draught is thus prevented, yet vessels of 300 tons can come up to the quays in the turn of spring tides. The increase of trade has been very considerable of late years. The number of vessels that entered in 1800, was 65; in 1830, 540, but in 1834 the number fell to 391. The export of oats in 1831, was 130,000 quarters; in 1832, 134,000; and in 1833, 154,000. That of wheat trebled itself in the three years ending with 1833, but the quantities were still small as compared with the oats, amounting in 1833 to no more than 3127 quarters. The export of butter and pork is also increasing rapidly, and steadily; no fewer than 150,000 casks of the former, and 8547 barrels of the latter, having been shipped in 1833. The increased demand in Great Britain for grain and provisions, has produced a considerable change in the cultivation of the soil, both in enlarged extent, and superior skill applied to tillage-land. The exports in 1835 amounted to L.369,490, estimated value, the principal being of grain, 504,803 cwts., value L.25,240; and provisions, 55,389 cwts., value L.181,836. The imports of the same year amounted to L.124,692, of which the principal were, tobacco, 101,066 lbs., L.16,450; salt, 90,640 bushels, L.6,728; British spirits, 33,000 gallons, L.11,000; and tea, 20,186 lbs., L.4037. Both exports and imports are chiefly confined to the cross-channel trade. The revenue of customs and excise duties has not increased in the same proportion. The amount of each, at various periods, is as follows:

Customs.

1802	L.14,690	1821	L.26,083
1803	14,747	1824	33,619
1804	11,462	1829	46,151
1805	16,201	1830	39,438
1806	16,772	1831	33,162
1807	14,567	1832	26,631
1808	18,699	1833	28,954
1809	20,309	1834	34,916
1810	15,133	1835	33,703
1811	13,101	1836	35,864
1812	10,651	1837	32,120
1813	16,138		

Excise.

1828	L.39,484	1832	L.31,654
1829	37,823	1833	24,040
1830	40,069	1835	33,507
1831	39,741	1836	35,864

The regulations of the port and harbour are placed under the commissioners of the town police, already noticed, who are authorised to assess a tax at a maximum of 2s. 6d in the pound, on all houses of L.5, and upwards, annual value, for all the purposes under the acts.

The population of Sligo town, and of the only other town of any note in the country, was in 1831, Sligo, 15,152; Ardmaree, 2,47.

SLING, an instrument serving for casting stones with great violence. The inhabitants of the Balearic islands were famous in antiquity for the dexterous management of the sling. It is said they used three kinds of slings, some longer, and others shorter, which they used according as their enemies were either nearer or more remote. It is added, that the first served them for a head-band, the second for a girdle, and the third they constantly carried in their hand.

SLINGING is used variously at sea, but chiefly for hoisting up casks or other heavy things with slings, that is, contrivances of ropes spliced into themselves at either end, with one eye big enough to receive the cask or whatever is to be slung. There are other slings, which are made longer, and with a small eye at each end, one of which is put over the breech of a piece of ordnance, and the other comes over the end of an iron crow, which is put into the mouth of the piece, to weigh and hoist the gun as they please. There are also slings by which the yards are bound fast to the cross-trees aloft, and to the head of the mast, with a strong rope or chain, that if the tie should happen to break, or to be shot to pieces in fight, the yard, nevertheless, may not fall upon the hatches.

Slinging a Man overboard, in order to stop a leak in a ship, is managed thus. The man is trussed up about the middle in a piece of canvass, and a rope to keep him from sinking, with his arms at liberty, a mallet in one hand, and a plug, wrapped in oakum and well tarred in a tarpauling clout, in the other, which he is to beat with all dispatch into the hole or leak.

SLIPPER Island, a small island in the Eastern sea. Long. 93. 30. E. Lat. 14. 8. N.

SLOANE, Sir Hans, eminently distinguished as a physician and a naturalist, was of Scotish extraction, his father, Alexander Sloane, having been at the head of that Scotish colony which King James I. settled in the north of Ireland, where the son was born, at Killieagh, on the 19th of April 1660. At a very early period, he displayed a strong inclination for natural history; and this propensity being encouraged by a suitable education, he employed those hours which young people generally lose by pursuing low and trifling amusements, in the study of nature, and contemplating her works. When about sixteen, he was attacked by a spitting of blood, which threatened to be attended with considerable danger, and which interrupted the regular course of his application for three years. He had, however, already learned enough of physic to know that a malady of this kind was not to be suddenly removed, and he prudently abstained from wine and other liquors that were likely to increase it.

By strictly observing this severe regimen, which he in some measure continued ever afterwards, he was enabled to prolong his life beyond the ordinary bounds; being an example of the truth of his own favourite maxim, that sobriety, temperance, and moderation, are the best and most powerful preservatives that nature has granted to mankind. As soon as he recovered from this infirmity, he resolved to perfect himself in the different branches of physic, which was the profession he had made choice of; and with this view he repaired to London, where he hoped to receive that assistance which he could not find in his own country.

On his arrival in the metropolis, he entered himself as a pupil of Stafforth, an excellent chemist, bred under the illustrious Stahl; and by his instructions he gained a perfect knowledge of the composition and preparation of the different kinds of medicines then in use. At the same time, he studied botany at the garden at Chelsea, assiduously attended the public lectures of anatomy and physic, and in short neglected nothing that he thought likely to prove serviceable to him in his future practice. His principal merit, however, was his knowledge of natural history; and it was this part of his character which introduced him early to the acquaintance of Mr. Boyle and Mr. Ray, two of the most eminent naturalists of that age. His intimacy with these distinguished characters continued as long as they lived; and as he was careful to communicate to them every object of curiosity that attracted his attention, the observations which he occasionally made often excited their admiration and obtained their applause.

After studying four years at London with unremitting severity, Mr. Sloane determined to visit foreign countries for further improvement. In this view he set out for France in the company of two other students, and having crossed to Dieppe, proceeded to Paris. In the way thither they were elegantly entertained by M. Lemery the elder; and in return Mr. Sloane presented that eminent chemist with a specimen of four different kinds of phosphorus, of which, upon the credit of other writers, M. Lemery had treated in his book of chemistry, though he had never seen any of them. At Paris Mr. Sloane lived as he had done in London. He attended the hospitals, heard the lectures of Tournefort, De Verney, and other eminent masters; visited all the literati, who received him with particular marks of esteem; and employed himself wholly in study.

From Paris he proceeded to Montpellier; and, being furnished with letters of recommendation from M. Tournefort to M. Chirac, then chancellor of that university, he found easy access, through his means, to all the learned men of the province, particularly to M. Magnol, whom he always accompanied in his botanical excursions in the environs of that city, where he beheld with pleasure and admiration the spontaneous productions of nature, and learned under his instructions to class them in a proper manner.

Having here found an ample field for contemplation, which was entirely suited to his taste, he took leave of his two companions, whom a curiosity of a different kind led into Italy. After spending a whole year in collecting plants, he travelled through Languedoc with the same design; and passing through Toulouse and Bordeaux, returned to Paris, where he made a short stay. About the end of the year 1684 he set out for England, with an intention of settling there as a physician. On his arrival in London, he made it his first business to visit his two illustrious friends Mr. Ray and Mr. Boyle, in order to communicate to them the discoveries which he had made in his travels. The latter he found at home, but the former had retired to Essex; to which place Mr. Sloane transmitted a great variety of plants and seeds, which Mr. Ray has described in his *History of Plants*, and for which he makes a proper acknowledgment.

About the year 1706 Sloane became acquainted with Sydenham, who soon contracted so warm an affection for him that he took him into his house, and recommended him in the strongest manner to his patients. He had not been long in London before he was proposed by Dr. Martin Lister as a candidate to be admitted a fellow of the Royal society, on the 26th of November 1684; and being approved, he was elected on the 21st of January following.

In 1685 he communicated some curiosities to the Society; and in July the same year he was a candidate for the office of assistant secretary, but without success, as he was obliged to give way to the superior interest of his competitor Dr. Halley. On the 12th of April 1687, he was chosen a fellow of the College of Physicians in London; and the same year his friend and fellow traveller Dr. Tancred Robinson, having mentioned to the society the plant called the star of the earth as a remedy newly discovered for the bite of a mad dog, Dr. Sloane acquainted them that this virtue of the plant was to be found in a book called De Grey's *Farriery;* and that he knew a man who had cured with it twenty couple of dogs. This observation he made on the 13th of July, and on the 12th of September following he embarked at Portsmouth for Jamaica with the duke of Albemarle, who had been appointed governor of that island. The doctor attended his grace in quality of physician, and arrived at Jamaica on the 19th of December following. Here a new field was opened for fresh discoveries in natural productions; but the world would have been deprived of the fruits of them, had not Sloane, by incredible application, converted, as we may say, his minutes into hours. The duke of Albemarle died soon after he landed, and the duchess determined to return to England whenever an answer should be received to the letter which she had sent to court on that melancholy occasion. As he could not think of leaving her grace in her distress, whilst the rest of her retinue were preparing for their departure, he improved it in making collections of natural curiosities; so that, though his whole stay in Jamaica was not above fifteen months, he brought together such a prodigious number of plants, that on his return to England, Mr. Ray was astonished that one man could procure in one island, and in so short a space, so vast a variety.

On his arrival in London, he applied himself to the practice of his profession, and soon became so eminent, that he was chosen physician to Christ's Hospital on the 17th October 1694; and this office he held till the year 1730, when, on account of his great age and infirmities, he found it necessary to resign. It is somewhat singular, and redounds much to the doctor's honour, that though he received the emoluments of his office punctually, because he would not lay down a precedent which might hurt his successors, yet he constantly applied the money to the relief of those who were the greatest objects of compassion in the hospital, that it might never be said he enriched himself by giving health to the poor. He had been elected secretary to the Royal Society on the 30th of November 1693; and upon this occasion he revived the publication of the *Philosophical Transactions*, which had for some time been neglected. He continued to be the editor of this work till the year 1712; and the volumes which appeared during that period are monuments of his industry and ingenuity, many of the pieces contained in them being written by himself.

In the mean time he published *Catalogus Plantarum quæ in Insula Jamaica sponte proveniunt; seu Prodromi Historiæ Naturalis pars prima;* which he dedicated to the Royal Society and the College of Physicians. About the same time he formed the plan of a dispensary, where the poor might be furnished at prime cost with such medicines as their several maladies might require; and this he afterwards carried into execution, with the assistance of the president and other members of the College of Physicians.

His eager thirst for natural knowledge seems to have been born with him, so that his cabinet of curiosities may be said to have commenced with his being. He was continually enriching and enlarging it; and the fame which, in the course of a few years, it had acquired, brought every thing that was curious in art or nature to be first offered to him for purchase. These acquisitions however increased it but very slowly in comparison of the augmentation which it received in 1701 by the death of Mr. William Courten, a gentleman who had employed all his time, and the greater part of his fortune, in collecting rarities, and who bequeathed the whole to Dr. Sloane, on condition of his paying certain debts and legacies with which he had charged it. These terms our author accepted, and he executed the will of the donor with the most scrupulous exactness; on which account some people have said, that he purchased Mr. Courten's curiosities at a dear rate.

In 1707 the first volume of Dr. Sloane's Natural History of Jamaica appeared in folio, though the publication of the second was delayed till 1725. By this very useful as well as magnificent work, the materia medica was enriched with a great number of excellent drugs not before known. In 1708 the author was elected a foreign member of the Royal Academy of Sciences at Paris, in the room of Mr. Tschirnaus; an honour so much the greater, as we were then at war with France, and the queen's express consent was necessary before he could accept it. In proportion as his credit rose among the learned, his practice increased among the people of rank. Queen Anne herself frequently consulted him, and in her last illness was blooded by him.

On the advancement of George I. to the throne, that prince, on the 3d of April 1716, created Sloane a baronet, an hereditary title of honour to which no English physician had before attained; and at the same time made him physician-general to the army, in which station he continued till 1727, when he was appointed physician in ordinary to George II. He attended the royal family till his death; and was particularly favoured by Queen Caroline, who placed the greatest confidence in his prescriptions. In the mean time he had been unanimously chosen one of the elects of the College of Physicians on the 1st of June 1716, and he was elected president of the same body on the 30th of September 1719, an office which he held for sixteen years. During that period he not only gave the highest proofs of his zeal and assiduity in the discharge of his duty, but in 1721 made a present to that society of L.100, and so far remitted a very considerable debt, which the corporation owed him, as to accept it in such small sums as were least inconvenient to the state of their affairs. Sir Hans was no less liberal to other learned bodies. He had no sooner purchased the manor of Chelsea, than he gave the company of apothecaries the entire freehold of their botanical garden there, upon condition only that they should present yearly to the Royal Society fifty new plants, till the number should amount to two thousand.[1] He gave besides several other considerable donations for the improvement of this garden, the situation of which, on the banks of the Thames, and in the neighbourhood of the capital, was such as to render it useful in two respects; first, by producing the most rare medicinal plants; and, secondly, by serving as an excellent school for young botanists, an advantage which he himself had derived from it in the early part of his life.

The death of Sir Isaac Newton, which happened in 1727, made way for the advancement of Sir Hans to the presidency of the Royal Society. He had been vice-president, and frequently sat in the chair for that great man; and by his long connection with this learned body he had contracted so strong an affection for it, that he made them a present of an hundred guineas, caused a curious bust of Charles II. its founder, to be erected in the great hall where it met, and, as is said, was very instrumental in procuring Sir Godfrey Copley's benefaction of a medal of the value of five guineas, to be annually given as an honorary mark of distinction to the person who communicates the best experiments to the Society.

On his being raised to the chair, Sir Hans laid aside all thoughts of further promotion, and applied himself wholly to the faithful discharge of the duties of the offices which he enjoyed. In these laudable occupations he employed his time, from 1727 to 1740, when, at the age of fourscore, he formed a resolution of quitting the service of the public, and of living for himself. With this view he resigned the presidency of the Royal Society much against the inclination of that respectable body, who chose Mr. Martin Folkes to succeed him, and in a public assembly thanked him for the great and eminent services which he had rendered them. In the month of January 1741, he began to remove his library, and his cabinet of rarities, from his house in Bloomsbury to that at Chelsea; and on the 12th of March following, having settled all his affairs, he retired thither himself, to enjoy in peaceful tranquillity the remains of a well-spent life. He did not however bury himself in that solitude which excludes men from society. He received in Chelsea, as he had done in London, the visits of people of distinction, of learned foreigners, and of the royal family, who sometimes did him the honour to wait on him; but, what was still more to his praise, he never refused admittance or advice to rich or poor who came to consult him concerning their health. Not contented with this contracted method of doing good, he now, during his retreat, presented to the public such useful remedies as success had warranted, during the course of a long-continued practice. Among these, is the efficacious receipt for distempers in the eyes, and his remedy for the bite of a mad dog.

During the whole course of his life, Sir Hans had lived with so much temperance, as had preserved him from feeling the infirmities of old age; but in his ninetieth year he began to complain of pains, and to be sensible of a universal decay. He was often heard to say, that the approach of death brought no terrors along with it; that he had long expected the stroke; and that he was prepared to receive it whenever the great Author of his being should think fit. After a short illness of three days, he died on the 11th o. January 1752, and was interred on the 18th at Chelsea, in the same vault with his lady, the solemnity being attended with the greatest concourse of people, of all ranks and conditions, that had ever before been seen on the like occasion.

---

[1] This garden was first established by the company in 1673; and having, after that period, been stocked by them with a great variety of plants, for the improvement of botany, Sir Hans, in order to encourage so serviceable an undertaking, granted to the company the inheritance of it, being part of his estate and manor of Chelsea, on condition that it should be for ever preserved as a physic garden. As a proof of its being so maintained, he obliged the company, in consideration of the said grant, to present yearly to the Royal Society, in one of their weekly meetings, fifty specimens of plants that had been grown in the garden the preceding year, and which were all to be specifically distinct from each other, until the number of two thousand should be completed. This number was completed in the year 1761. In 1733 the company erected a marble statue of Sir Hans, executed by Rysbrac, which is placed upon a pedestal in the centre of the garden, with a Latin inscription, expressing his donation, and the design and advantages of it.

Sir Hans being extremely solicitous lest his cabinet of curiosities, which he had taken so much pains to collect, should be again dissipated at his death, and being at the same time unwilling that so large a portion of his fortune should be lost to his children, bequeathed it to the public, on condition that L.20,000 should be made good by parliament to his family. The sum, though large in appearance, was scarcely more than the intrinsic value of the gold and silver medals, the ores and precious stones that were found in it; for in his last will he declares, that the first cost of the whole amounted at least to L.50,000. Besides his library, consisting of more than fifty thousand volumes, three hundred and forty-seven of which were illustrated with cuts finely engraven and coloured from nature, there were three thousand five hundred and sixty manuscripts, and an infinite number of rare and curious works of every kind. The parliament accepted the legacy, and fulfilled the conditions.

SLOBODSK-UKRAINE, a province of European Russia, which extends in north latitude from 48° 35′ to 51° 16′, and in east longitude from 34° 10′ to 38° 21′, comprehending 26,217 square miles. It is an elevated plain, over which few hills are to be seen. It contains but few forests, and the soil is generally dry, but by no means unfruitful. There are many small rivulets and rivers, which discharge their waters into either the Don or the Dnieper. The climate is considered healthy, though intensely hot in summer, and as severely cold in winter. The land varies in quality, but much of it is highly productive in corn. The inhabitants are of various races, some of them of Little Russian origin, others Cossacs, others from Great Russia, many called colonists, consisting chiefly of Germans or Poles, a few Kalmucks, and many Jews. The whole population is 718,500, the far greater part of whom adhere to the Greek church, but there are Arminians, Catholics, Lutherans, and a few Mahomedans and Pagans. The province is divided into twelve circles, and contains 15 cities, 547 parishes, with 1180 market-towns and villages. The capital is Charkow, or Kharkow, in latitude 49. 59. 20., and longitude 36. 10. E.

SLOT, in the sportsman's language, a term used to express the mark of the foot of a stag or other animal proper for the chace in the clay or earth, by which they are enabled to guess when the animal passed, and which way he went. The slot, or treading of the stag, is very nicely studied on this occasion. If the slot be large, deeply imprinted in the ground, and with an open cleft, and, added to these marks, there is a large space between mark and mark, it is certain that the stag is an old one. If there be observed the slots or treadings of two, the one long and the other round, and both of one size, the long slot is always that of the larger animal. There is also another way of knowing the old ones from the young ones by the treading; which is, that the hinder feet of the old ones never reach to their fore feet, whereas those of the young ones do.

SLOUGH, a market town of the county of Buckingham, in the hundred of Stoke. Though a town it is not a parish, one part being within the parish of Upton, and another part in the parish of Stoke Poggis. It is twenty miles from London and two from Eton, and is furnished with excellent inns, being on the great road to Bath and Bristol. It has a market on Thursday. It is chiefly remarkable from having been the residence of the celebrated astronomer Dr. Herschel, who constructed, in a garden near the road, his large and invaluable telescope, and made those discoveries in the heavens which have immortalised his name.

SLUICE, a frame of timber, stone, or other matter, serving to retain and raise the water of a river, and on occasion to let it pass.

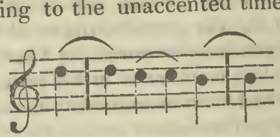
Such is the sluice of a mill, which stops and collects the water of a rivulet, to let it fall at length in greater plenty upon the mill-wheel; such also are those used as vents or drains to discharge water off land; and such are the sluices of Flanders, which serve to prevent the waters of the sea from overflowing the lower lands.

Sometimes there is a kind of canal inclosed between two gates or sluices, in artificial navigations, to save the water, and render the passage of boats equally easy and safe, upwards and downwards; as in the sluices of Briare in France, which are a kind of massive walls built parallel to each other, at the distance of twenty or twenty-four feet, closed with strong gates at each end, between which is a kind of canal or chamber, considerably longer than broad; in which a vessel being inclosed, the water is let out at the first gate, by which the water is raised fifteen or sixteen feet, and passed out of this canal into another much higher. By such means a boat is conveyed out of the Loire into the Seine, though the ground between them rises above one hundred and fifty feet higher than either of those rivers.

Sluices are made in different ways, according to the use for which they are intended. When they serve for navigation, they are shut with two gates, presenting an angle towards the stream; when they are made near the sea, two pair of gates are made, the one to keep the water out and the other in, as occasion requires. In this case, the gates towards the sea present an angle that way, and the others the contrary way; and the space inclosed by those gates is called the *chamber*. When sluices are made in the ditches of a fortress, to keep up the water in some parts, instead of gates, shutters are made so as to slide up and down in grooves; and when they are made to raise an inundation, they are then shut by means of square timbers let down in cullises, so as to lie close and firm.

The word *sluice* is formed of the French *escluse*, which Ménage derives from the Latin *exclusa*, which is found in the Salic law in the same sense. But this is to be restricted to the sluices of mills, for as to those serving to raise vessels, they were wholly unknown to the ancients.

SLUR, in *Musical Notation*, a curved line drawn over two or more notes, signifying, that these are to be performed in a smooth and connected manner *(legato.)* When the slur is applied to two notes of the same degree, this generally occurs in what is called a *syncopation*, *i. e.* where a note of the accented time of the measure is united with a note of the same name belonging to the unaccented time immediately preceding, thus:



SLUYS, a town of Dutch Flanders, opposite the island of Cadsand, with a good harbour, ten miles north of Bruges, containing 14,000 inhabitants. Long. 3. 25. E. Lat. 51. 19. N.

SLUZK, a city, the capital of a circle of the same name, in the province of Minsk in West Russia, 715 miles from St. Petersburg. It is situated on a river which gives it its name, is the best city in the province, contains two Catholic, two Greek, a Lutheran, and a Reformed church, and 1000 houses, with 5800 inhabitants, among whom are many Jews. There is a public school or college, where mathematics and natural philosophy are taught. Its chief employment is in agriculture. Lat. 53. 3. Long. 27. 22. E.

SMACK, a small vessel, commonly rigged as a sloop or hoy, used in the coasting or fishing trade, or as a tender in the king's service.

SMALAND, a province in the south of Sweden. See CALMAR.

SMALKALD, a town of Germany, in Franconia, and in the county of Henneberg; famous for the confederacy entered into by the German Protestants against the emperor, commonly called the *league of Smalkald*. The design of it was to defend their religion and liberties. It is seated on the river Werra, twenty-five miles south-west of Erford, and fifty north-west of Bamberg. Long. 10. 53. E. Lat. 50. 40. N. It is subject to the prince of Hesse-Cassel.

SMALL KEY, a small island in the Eastern Sea. Long. 247. 16. W. Lat. 10. 37. N.

SMALT, a kind of glass of a dark blue colour, which when levigated appears of a most beautiful colour; and if it could be made sufficiently fine, would be an excellent succedaneum for ultramarine, as not only resisting all kinds of weather, but even the most violent fires. It is prepared by melting one part of calcinated cobalt with two of flint powder, and one of potash. At the bottoms of the crucibles in which the smalt is manufactured, we generally find a regulus of a whitish colour inclined to red, and extremely brittle. This is melted afresh, and when cold, separated into two parts; that at the bottom is the cobaltic regulus, which is employed to make more of the smalt; the other is bismuth.

SMEATON, JOHN, an eminent civil engineer, was born on the 18th of June 1724, at Austhorpe, near Leeds, in a house built by his grandfather, and where his family have resided ever since.

The strength of his understanding and the originality of his genius appeared at an early age. His playthings were not the playthings of children, but the tools which men employ; and he appeared to have greater entertainment in seeing the men in the neighbourhood work, and asking them questions, than in any thing else. One day he was seen on the top of his father's barn, fixing up something like a windmill; another time, he attended some men fixing a pump at a neighbouring village, and observing them cut off a piece of bored pipe, he was so lucky as to procure it, and he actually made with it a working pump that raised water. These anecdotes referred to circumstances that happened while he was yet in petticoats, and most likely before he attained his sixth year.

About his fourteenth or fifteenth year, he constructed for himself an engine for turning, and made several presents to his friends of boxes in ivory or wood very neatly turned. He forged his iron and steel, and melted his metal; he had tools of every sort for working in wood, ivory, and metals. He made a lathe, by which he cut a perpetual screw in brass, a thing little known at that day, which was the invention of Mr. Henry Hindley of York, with whom Mr. Smeaton soon became acquainted, and they spent many a night at Mr. Hindley's house till day-light, conversing on those subjects.

Thus had Mr. Smeaton, by the strength of his genius and indefatigable industry, acquired, at the age of eighteen, an extensive set of tools, and the art of working in most of the mechanical trades, without the assistance of any master. A part of every day was generally occupied in forming some ingenious piece of mechanism.

Mr. Smeaton's father was an attorney, and desirous of bringing him up to the same profession. Mr. Smeaton therefore came up to London in 1742, and attended the courts in Westminster hall; but finding that the law did not suit the bent of his genius, he wrote a strong memorial on that subject to his father, whose good sense from that moment left the youth to pursue the bent of his genius in his own way.

In 1751, he began a course of experiments to try a machine of his invention to measure a ship's way at sea, and also made two voyages in company with Dr. Knight to try it, and a compass of his own invention and making, which was rendered magnetical by Dr. Knight's artificial magnets. The second voyage was made in the Fortune sloop of war, commanded at that time by Captain Alexander Campbell.

In 1753 he was elected member of the Royal Society. The number of papers published in their Transactions will show the universality of his genius and knowledge. In 1759 he was honoured by an unanimous vote with their gold medal for his paper entitled "An Experimental Inquiry concerning the Natural Powers of Water and Wind to turn Mills, and other Machines depending on a circular motion." This paper, he says, was the result of experiments made on working models in the years 1752 and 1753, but not communicated to the Society till 1759; before which time he had an opportunity of putting the effect of these experiments into real practice, in a variety of cases, and for various purposes, so as to assure the Society he had found them to answer.

In December 1755, the Eddystone lighthouse was burned down. Mr. Weston, the chief proprietor, and the others, being desirous of rebuilding it in the most substantial manner, inquired of the Earl of Macclesfield, then president of the Royal Society, whom he thought the most proper to rebuild it; and his lordship recommended Mr. Smeaton. He accordingly undertook the work, and he completed it in the summer of 1759. Of the preparation for this extraordinary work, of its commencement and progress, Mr. Smeaton has given an ample and interesting description in a splendid folio volume which was first published in 1791. The same volume contains the history of the different buildings which have been erected on the Eddystone rock.

Though Mr. Smeaton completed the building of the Eddystone lighthouse in 1759, yet it appears he did not soon get into full business as a civil engineer; but in 1764, while in Yorkshire, he offered himself a candidate to be one of the receivers of the Derwentwater estate, and on the 31st of December in that year, he was appointed at a full board of Greenwich hospital, in a manner highly flattering to himself, when other two persons, strongly recommended and powerfully supported, were candidates for the employment.

Mr. Smeaton having now got into full business as a civil engineer, performed many works of general utility. He made the Calder navigable; a work that required great skill and judgment, owing to the very impetuous floods in that river. He planned and attended the execution of the great canal in Scotland for conveying the trade of the country either to the Atlantic or German Ocean; and having brought it to the place originally intended, he declined a handsome yearly salary, in order that he might attend to the multiplicity of his other business.

The vast variety of mills which Mr. Smeaton constructed, so greatly to the satisfaction and advantage of the owners, will show the great use which he made of his experiments in 1752 and 1753; for he never trusted to theory in any case where he could have an opportunity to investigate it by experiment. He built a steam-engine at Austhorpe, and made experiments upon it, purposely to ascertain the power of Newcomen's steam-engine, which he improved and brought to a greater degree of perfection, both in its construction and powers, than it was before.

About the year 1785 Mr. Smeaton's health began to decline; and he then took the resolution of endeavouring to avoid all the business he could, so that he might have leisure to publish an account of his inventions and works, which was certainly the first wish of his heart; for he has often been heard to say, that "he thought he could not render so much service to his country as by doing that." He got only his account of the Eddystone lighthouse completed, and some preparations to his intended *Treatise on Mills;* for he could not resist the solicitations of his friends in various works; and Mr. Aubert, whom he greatly loved and respected, being chosen chairman of Ramsgate harbour, prevailed upon him to accept the place of engineer to that harbour. To their joint efforts the public is chiefly indebted for the improvements which have been made there, as fully appears in a report that Mr. Smeaton presented to the board of trustees in 1791, which they immediately published.

Mr. Smeaton being at Austhorpe, walking in his garden on the 16th of September 1792, was struck with palsy, and died the 28th of October.

SMELL, a word which in most languages has two meanings, signifying either that sensation of mind of which we are conscious, in consequence of certain impressions made on the nostrils, and conveyed to the brain by the olfactory nerves; or that unknown virtue, or quality in bodies, which is the cause of our sensations of smell.

SMELLIE, William, a learned and ingenious printer, was born at Edinburgh in the year 1740. His father, Alexander Smellie, who followed the occupation of a master-builder, is said to have been a classical scholar, and a writer of Latin verses. He belonged to the sect of reformed Presbyterians, more commonly described as Cameronians. He left two sons and three daughters. John, the elder son, followed his father's employment, and married a sister of the late James Ferrier, Esq. clerk of session. Two of his daughters were likewise married. Residing in the suburban street called the Pleasance, he sent his younger son to Duddingstone school, which is scarcely a mile distant. William Smellie was there initiated in the ordinary branches of education, including the Latin language; but he left school at the early age of twelve, and was destined to follow some mechanical employment. It was his father's original intention to bind him an apprentice to a staymaker, but some difference occurred as to the terms of the indenture; "and the young scholar was preserved from the mortifying drudgery of scraping whalebone, and stitching coats of armour to force the female form into every shape save that of natural elegance." On the first of October 1752, he was bound an apprentice, for six years and a half, to Hamilton, Balfour, and Neill, printers to the university.

To this occupation he applied himself with great assiduity, and he soon became conspicuous for the rapidity, as well as the correctness, with which he dispatched his work. With equal assiduity he devoted his evenings to the acquisition of knowledge. Two years before the expiration of his apprenticeship, his masters appointed him a corrector of the press, with a weekly allowance of ten shillings, which at that period was no despicable remuneration. His father was now dead, and two of his sisters were materially indebted to him for their support. During his apprenticeship, he was permitted to attend some of the academical lectures. The printing-office was within the precincts of the university buildings; "and he generally continued at work till he heard the bell ring for lecture, when he immediately laid down his composing-stick, shifted his coat, ran off with his note-book under his arm, and returned to his work immediately after lecture." The Edinburgh Philosophical Society having offered a silver medal for the most accurate edition of a Latin classic, Smellie set and corrected an edition of Terence, which obtained this prize for his employers. His edition, which bears the date of 1758, but was actually printed during the preceding year, has been described as immaculate; but of the literal accuracy of this description, we entertain some doubt. It is very elegantly printed, and is in all respects creditable to the Edinburgh press of that period. His apprenticeship was completed on the first of April 1759; and in the ensuing month of September, he agreed to transfer his services to the office of Murray and Cochrane. Here he was not only to perform the ordinary work of a corrector, but was likewise to collect articles for the Scots Magazine, and to make abstracts, extracts, or transcripts of such pieces as his employers should direct. He was moreover to lend his aid "in writing accounts, and, in cases of hurry in printing, in composing or case-work;" and in return for these various services, he was to receive a weekly salary of sixteen shillings.

It was one advantage of his new situation, that his employers allowed him three hours a-day for the prosecution of his academical studies; and thus, under peculiar circumstances, he was enabled to obtain a regular education. He not only studied the Latin, Greek, and Hebrew languages, but likewise mathematics, logic, rhetoric, moral, and natural philosophy. He besides attended all the medical courses, including the lectures on chemistry and botany. The Hebrew class he attended in the year 1758, with the immediate view of preparing himself to superintend the printing of Dr. Robertson's Hebrew Grammar. His course of study had thus been so regular and complete, that he was in a state of mature preparation for more than one of the learned professions. Some of his friends recommended the study of divinity; Dr. Buchan urged him to betake himself to the practice of physic; but the hazard of relinquishing a certain though small income for a very uncertain experiment, must have served to mancipate him to his original avocation. An early marriage fixed him more completely in the printing-office. His wife, Jane Robertson, was the daughter of an army-agent in London, who had once been opulent, but who finally left his family in indigent circumstances. Her mother was the cousin of Mrs. Oswald of Dunikier, and there were other family connexions described as genteel, but they do not appear to have rendered any service to Smellie or his children. The marriage took place in 1763, when he had only attained the twenty-third year of his age.

In the mean time, his love of learning suffered no abatement. In the year 1760 he had become a member of the Newtonian Society, a literary association chiefly composed of young men educated in the university. They held their weekly meetings in one of the class-rooms. At each meeting an essay was read by one of the members; and a subject, previously assigned, was discussed in due form. The essays were restricted to subjects of natural science, but the debates extended to a wider range. The list of members included various names which were afterwards conspicuously known; and among others, we find that of Robert Blair, the late president of the court of session. To this association likewise belonged Thomas Blacklock, Robert Hamilton, Alexander Adam, Henry Hunter, Samuel Charters, and William Buchan. After the interruption of their regular meetings as a society, some of the members continued for several years to hold a weekly meeting in a tavern, where they partook of a sober repast, and spent their evenings in literary and social conversation. With two very estimable members of this club, Dr. Hamilton of Aberdeen, and Dr. Charters of Wilton, Smellie always retained a friendly connexion. A new association, of which he acted as secretary, was formed in the year 1778, under the denomination of the Newtonian Club. Most of the other members were connected with the medical profession, and five of them either then were or afterwards became medical professors in the university. In the list of these associates we find the names of Dugald Stewart and James Gregory. No person was eligible unless he was a member of the Philosophical Society; and the meetings of the club were appointed to take place immediately after the close of each meeting of the society. The number of members was not to exceed twenty; and a single black ball was to exclude any candidate. The last of their regulations stands thus: "As this club consists entirely of philosophers, it would therefore be ridiculous to make any laws for its internal police."

For the different branches of natural history Smellie had evinced an early predilection. To the study of botany he devoted so much attention, that in 1765 his Dissertation on the Sexes of Plants gained the gold medal given by Dr. Hope. In this dissertation, which was inserted in the first edition of the Encyclopædia, he strenuously opposed the doctrines of Linnæus.[1] The substance of it was incorporated in his Philosophy of Natural History; and his opinions were then controverted by Dr. Rotheram, afterwards professor of natural philosophy at St. Andrews. Of his proficiency in these studies we find a more conspicuous proof. While he was attending the botanical class, the professor sprained his leg so severely that for a considerable interval he was unable to meet his students; and on this occasion he selected Smellie to continue the course of lectures. In a botanic garden, lectures cannot be servilely read from papers, either written by the lecturer himself, or supplied by others.

On the 25th of March 1765 he commenced business as a printer, in conjunction with two brothers named Robert and William Auld, the former of whom was a solicitor. His private resources were obviously scanty; and two of his friends, Dr. Robertson, professor of oriental languages, and Dr Hope, professor of botany, advanced to him the sum of seventy pounds, which we reckon equivalent to two hundred in our present currency. This copartnery was dissolved within the space of less than two years, by the retirement of Robert Auld; but a new company, consisting of Balfour, W. Auld, and Smellie, commenced business on the 22d of December 1766. John Balfour, who was likewise a bookseller, had been a partner in the house of Hamilton, Balfour, and Neill. The new house published the Journal, a newspaper supposed to have been unprofitable. Their connexion only continued till the month of November 1771; and the modified firm of Balfour and Smellie continued the business from the twelfth of that month. Beside his share of the profits, the junior partner was to receive ninety pounds a-year, and he was bound to conduct the entire business of the office. His average income amounted to about L.200. After an interval of more than two years, he easily obtained from Lord Kames the favour of his becoming surety to the Royal Bank for a cash-account to the extent of two or three hundred pounds. Their acquaintance had arisen from a series of anonymous strictures which he communicated to his lordship when the Elements of Criticism were passing through the press of Murray and Cochrane. The author requested the acquaintance of his nameless critic, and afterwards honoured him with various marks of his friendly attention. He incidentally mentions his supping with Lord Kames, in company with Hume and other guests. He was likewise a guest at the learned suppers of Lord Monboddo; and he reckoned Lord Hailes, as well as Lord Gardenstone, among the number of his friends and well-wishers.

Balfour and Smellie were appointed printers to the university. The chief advantage which attended this appointment was the profit of printing the dissertations written by candidates for medical degrees. Smellie likewise printed the theses written by candidates for admission to the Faculty of Advocates; and his knowledge of the Latin language was in both cases found very serviceable to the writers. He rendered material assistance to his friend Dr. Buchan, in the composition of a work which attained to very extensive popularity. This work, entitled "Domestic Medicine, or, a Treatise on the Cure and Prevention of Diseases," was published at Edinburgh in the year 1770. In the course of forty years, it is said to have passed through twenty editions, each consisting of 6000 copies, besides many pirated editions in Ireland and America, and some even in Britain. Of this treatise, Smellie was sometimes represented as the sole author; but it appears with sufficient evidence that the manuscript was placed in his hands, and that in preparing it for the press, he made many essential alterations in its form and style. It was so diffuse and redundant, that a single chapter, as originally written, would nearly have equalled the size of the entire book, as at first printed. These services were compensated with a bill for one hundred pounds.

Of Smellie's life, we have now arrived at an era which recommends him to the more particular regard of the writers and readers of the present work. The first edition of the Encyclopædia Britannica consisted of only three volumes, which began to be printed in the year 1771. The principal articles were written, compiled, or devised by him, and he prepared and superintended the entire publication. "As you have informed me," says a letter of Andrew Bell, the chief proprietor, "that there are fifteen capital sciences which you will undertake for, and write up the subdivisions and detached parts, conform[ably] to your plan, and likewise to prepare the whole work for the press, &c. &c., we hereby agree to allow you L.200 for your trouble." If his capital sciences had not exceeded the old number of seven, this remuneration could scarcely have been considered as extravagant. One of his original articles, contributed to this edition, was that on *Æther*, which attracted a considerable degree of attention, and gave no small offence to Dr. Cullen, whose theory was there exposed, though without any mention of his name. From internal evidence, he was convinced that the article must have been written by his colleague Dr. John Gregory. He at length ascertained the real author; and this discovery, says the late Dr. Gregory, "gave occasion to the complete alteration and softening of the article Æther in the second and all the subsequent editions of the Encyclopædia; so that nothing of it was allowed to remain that could give offence to Dr. Cullen."[2]

Of the second edition of this work Smellie was offered a share, apparently a third, conjoined with the charge of editorship. This offer he unfortunately declined, and thus lost the only golden opportunity that fortune ever presented to him. "At the death of Mr. Macfarquhar, printer, in April 1793, the whole work became the property of Mr. Bell. It is well known that Mr. Macfarquhar left a handsome fortune to his family, all or mostly derived from the profits of the Encyclopædia; and that Mr. Bell died in great affluence, besides possessing the entire property of that vast work; every shilling of which may be fairly stated as having grown from the labours of Mr. Smellie in the original fabrication of the work, which is confessedly superior, and all of which he and his family might have shared in equally with Mr. Bell and the other proprietor, if he had not been too fastidious in his notions, and perhaps too timid in his views of the risk which might have been incurred in the mercantile part of the speculation."[3] His chief objection is stated, not with much probability, to have arisen from a difference of opinion as to the general plan: "because the other persons concerned, it has been said upon the suggestion of a very distinguished nobleman of the highest rank and most princely fortune, insisted upon the introduction of a system of general biography; which Mr. Smellie objected to, as by no means consistent with the title." If this statement is accurate, we consider the nobleman as decidedly right, and Smellie as decidedly wrong; inasmuch as the historical and biographical part of the work has recommended it to many readers, who do not feel an equal degree of interest in the arts and sciences. The perfection of such a work is to render it agreeable as well as instructive to the greatest possible number of readers. The second edition, consisting of 1500 copies, began to be published in 1776. The third, extending to no fewer than 10,000 copies of eighteen volumes, commenced in 1786. By this edition, we are informed, the two proprietors "are said to have cleared a net profit of L.42,000, besides being each paid for their respective work in the conduct of the publication as tradesmen; Mr. Bell as engraver of all the plates, and Mr. Macfarquhar as sole printer."

Smellie afterwards embarked in a speculation which did not prove so lucrative. This was "The Edinburgh Magazine and Review," of which the first number appeared in the month of October 1773. The editor was Dr. Stuart, whose temper and discretion were not equal to his talents and learning. Smellie was one of five partners, including the editor; and besides printing the work at the ordinary rates, he "was regularly to compile the last half-sheet of every number, to consist of foreign and domestic occurrences, or the news-department, and other articles; to keep the accounts of the concern; to answer all letters relative to the concern; and to review certain articles, as should be agreed upon between him and Dr. Stuart." The work only extended to five volumes, closing with the number for August 1776. It was conducted with so much ability, that it might have run a more prosperous career, if the personalities of the editor, displayed within so narrow a field, had not excited a degree of hostility with which it was hopeless to contend. But the history of this work will be resumed in our notice of Gilbert Stuart.

Of the Society of Antiquaries, instituted at Edinburgh in 1780, Smellie was an original member. In 1781 he was elected Superintendent of the Museum of Natural History, which they proposed adding to their antiquarian cabinet. He afterwards published an "Account of the Institution and Progress of the Society of the Antiquaries of Scotland." Edinb. 1782, 4to. To this account he added a second part in 1784. He was elected to the office of secretary in 1793. This new institution excited the jealousy of some other learned bodies. The senate of the university presented a memorial to the lord advocate, remonstrating against the grant of a royal charter to the Society of Antiquaries, on the allegation that Scotland was too limited a country for two literary Societies; and proposing, that instead of granting such a charter, the king should incorporate a society under the designation of the Royal Society of Scotland. They further suggested "that the Society of Antiquaries would intercept the communication of many specimens and objects of natural history, which would otherwise be deposited in the museum of the university, and of many documents tending to illustrate the history, antiquities, and laws of Scotland, from being deposited in the library of the Faculty of Advocates. They likewise noticed that the possession of a museum of natural history might enable and induce the Society of Antiquaries to institute a lectureship of natural history, in opposition to the professorship in the university." Nor did the curators of the Advocates Library remain inactive. They represented to the lord advocate that the grant of a charter to the Antiquaries "might prove injurious to that magnificent library, by intercepting ancient manuscripts and monuments illustrative of the history and antiquities of Scotland, which would be more useful when collected into one repository than in a state of division." To all these representations the Society returned an elaborate answer, in the form of a memorial addressed to the lord advocate; and the royal charter was finally ratified in the month of May 1783. It is scarcely necessary to add, that few or none of the multifarious evils which had thus been predicted, were found to result from the incorporation of this Society, which has proved almost as harmless as any institution in the kingdom. The Royal Society of Edinburgh soon afterwards obtained its charter; and as a member of the Philosophical Society, Smellie was incorporated on the 23d of June 1783.

At the request of the Society of Antiquaries, he had in 1781 digested the plan of a statistical account of all the parishes of Scotland. The circulation of this plan did not excite much industry; but, at no distant period, it was followed by an extensive and important work. As superintendent of the museum, he was authorized to deliver in their hall a course of lectures on natural history. "His object was to deliver lectures on the philosophy of natural history, which is a subject totally different from what a public professor is obliged to teach. A professor must instruct his students in the technical and elementary part of the science; but the private lecturer was to confine himself to general views of the economy of nature."[1] The professor of natural history, who certainly had reason to fear such a rival, was alarmed at what he considered as an encroachment on his province, and this plan of lectures was reluctantly abandoned. On the death of Dr. Ramsay in the year 1775, Smellie had offered himself as a candidate for the professorship; but his claims were disregarded, and it was bestowed upon Dr. Walker, at that time minister of Moffat, and afterwards of Colinton.

Smellie however continued to prosecute his favourite study, and he published "Natural History, general and particular, by the Count de Buffon: translated into English. Illustrated with above 200 copper-plates, and occasional notes and observations by the Translator." Edinb. 1781, 8 vols. 8vo. "Much the greater portion of this extensive work," says Mr. Kerr, "was executed in a small correcting room or closet connected with his printing-office, where he was continually liable to interruption, from the introduction of proof-sheets for correction, and revises for comparison, and to the almost perpetual calls of customers, authors, and idle acquaintances: yet such was his accuracy of self-possession, that, as usual with almost every thing he wrote, he gave it out page by page, as fast as written, to his compositors, and hardly ever found it necessary to alter a single word after the types were set up from his first uncorrected manuscript. Although, to have enabled him to execute this translation in the excellent manner in which it is done, Mr. Smellie must necessarily have possessed a very thorough knowledge of the French language, it appears that he had acquired this entirely by means of his own private study, and without the assistance of any teacher; for we have been assured by those who knew him very intimately, that he was quite unacquainted with the pronunciation of French." A second edition of his translation, in nine volumes, followed in the year 1785. Other three editions, all of them extensive, were afterwards published; so that the work may be considered as having been eminently successful. The translator's notes were allowed to have added no inconsiderable value to the text; and the chief fault imputed to him was the use of provincial idioms. He was honoured with the correspondence of Buffon, and likewise of Pennant.

The firm of Balfour and Smellie having been dissolved, that of Creech and Smellie began business on the 14th of September 1782, and continued it till the close of the year 1789. Creech, well-known as a bookseller, was in all cases difficult to bring to a settlement of accompts, when he had any reason to believe the balance to be on the wrong side. The affairs of this copartnery, being somewhat intricate, were submitted to arbitration, and a balance was ultimately found due to Smellie; but the decision was so long deferred, that it was not pronounced till some time after his death. After the termination of these different partnerships, he continued the business on his own account. Lord Kames died in the year 1782; and he was now indebted to the kindness of Lord Gardenstone, who became his surety to the banking-house of Sir W. Forbes and Co.

---

[1] Smellie's Account of the Society of Antiquaries, part ii. p. 24.

His next publication was "An Address to the People of Scotland, on the Nature, Powers, and Privileges of Juries. By a Juryman." Edinb. 1784, 8vo. This tract is entitled to particular notice, because it contains a clear and judicious exposition of legal principles, very important in themselves, and at that period very little understood. "It is," he remarks, "a common notion that jurymen are judges of the *fact* only, and not of the *law*. This absurd, and often fatal prejudice is much more prevalent than might be expected, in a city like this, where general knowledge ought to be pretty widely diffused. It has perhaps been too much fostered by the injunctions of judges and magistrates. It is exceedingly natural that plain simple jurymen should look up with veneration to the high rank, and superior abilities of those men who are appointed by their sovereign to dispense justice over the nation. For this reason it is, that the English judges are so extremely solicitous not to inculcate their own opinions on the minds of jurymen, but to leave their determinations solely to the dictates of their own consciences. But from whatever source this prejudice may have derived its origin, I shall endeavour to shew that it has neither law nor common sense for its support." A further specimen may very satisfactorily be produced. "I know it to be the opinion of many jurymen, that after the court admits a *relevancy*, they are bound by their oaths to find the libel either *proved* or *not proved*. But these gentlemen should consider, that their business is to give a verdict of a very different kind. They are to judge both of the criminality of the culprit, and of his exculpatory evidence. The words *proved* or *not proved* should be for ever banished from the verdicts of juries. A relevancy may be found, when the jurymen, who hear the indictment impugned, are of an opposite opinion from the court. A crime may be libelled, when the facts related in the indictment, though completely proved, do not constitute the essence of the crime charged. Hence, whenever the minds of jurymen are convinced that a relevancy has been improperly found, their verdict, however the proof may stand, should be *Not guilty*. Indeed, the expressions, *Guilty* or *Not guilty* ought alone to be employed in verdicts." This tract excited a considerable degree of attention; and it was quoted with much approbation by Lord Erskine, in his famous speech in defence of Dr. Shipley, dean of St. Asaph. He published several other pamphlets, which chiefly related to local politics.

But the most elaborate of his works is "The Philosophy of Natural History." Edinb. 1790, 4to. This is an ingenious book, written in a very pleasing style, and it accordingly experienced a favourable reception. It was reprinted at Dublin and Philadelphia. Lichtenstein published a German translation, to which some notes were added by C. A. W. Zimmermann. For the original volume, Charles Elliot agreed to pay one thousand guineas, at six, twelve, and eighteen months, as well as a certain sum for every edition after the first. This enterprising bookseller died before the work was ready for publication; but the agreement was honourably fulfilled by his trustees, though the benefit accrued, not to the author himself, but to his family. "This," says Mr. Kerr, "was probably the largest sum that had ever been given, at least in Edinburgh, for the literary property of a single quarto volume, and evinced both the liberality of the bookseller, and the high estimation in which he very justly held the fame and talents of the author."

His plan however was not yet completed, and he immediately applied himself to the preparation of a second volume. He lived to bring it to a conclusion, though not to make any arrangement for its publication. During the last years of his life, his health appears to have been infirm and precarious. In June 1793, he stated to his friend Dr. Hutton, that he had for several months been distressed with a debility in his limbs, accompanied with a want of appetite; and to another medical friend, Dr. Gardiner, we find him stating very unfavourable symptoms in the course of the following year. After a long illness, he died on the 24th of June 1795, at the age of sixty-five. He left a widow, with four sons and four daughters; two sons and three daughters having died before their father. His eldest daughter was married to Mr. George Watson, an eminent portrait-painter in Edinburgh. Smellie had never been in affluent circumstances, but he left to his family the means of prosperity; and the printing business has been more successfully conducted by his son Mr. Alexander Smellie.

Of his Philosophy of Natural History, the second volume was published by this son in the year 1799. Another posthumous work speedily followed: "Literary and characteristical Lives of John Gregory, M.D., Henry Home, Lord Kames, David Hume, Esq., and Adam Smith, LL.D. To which are added a Dissertation on Public Spirit, and three Essays." Edinb. 1800, 8vo. His original plan comprehended the lives of other twenty-five men of literary eminence, with whom he was personally acquainted. One of these was his friend Dr. Stuart, with whose private history he was sufficiently familiar, and of which he could have supplied very curious, though perhaps not very edifying details. It is not however a subject of much regret that his plan was never completed. In the specimen with which we have thus been presented, there is too little biography, and too much discussion. This remark is more particularly applicable to the life of Dr. Gregory, which extends to 118 pages, but is almost entirely occupied with an account, not of the writer, but of his writings. The other lives are of less extent. In his account of Hume, he relates, without any symptom of disapprobation, the indecent levity with which he sported on the verge of another world; and in the same manner he likewise repeats the declaration of Dr. Smith as to the character of that philosopher, "I have always considered him, both in his lifetime and since his death, as approaching as nearly to the idea of a perfectly wise and virtuous man, as perhaps the nature of human frailty will permit." This ingenious printer may himself have been somewhat too anxious to be classed among philosophers.

Smellie appears to have been a man of excellent talents, and of extensive knowledge. His disposition was social, his habits were convivial, and he was distinguished by a sarcastic vein of wit and humour. According to the description of his biographer, he "was about the middle size, and had been in his youth well-looked and active; but when rather past the middle of life, he had acquired from almost constantly stooping at his desk to write or correct, a rather lounging gait and appearance; and from a long-continued series of difficulties in his affairs, and much disappointment in matters of affectionate moment, he had become careless and rather slovenly in his dress and appearance; wearing his hair long and bushy, his ordinary black and wide-made clothes ill brushed, and well sprinkled with snuff, and his usual old-fashioned cocked hat for the most part rusty." Burns describes him as "a man positively of the first abilities and greatest strength of mind, as well as one of the best hearts and keenest wits, that he had ever met with." And in the following lines, which allude to a club called the Crochallan Fencibles, he has exhibited a graphic delineation of Smellie:

To Crochallan came
The old cock'd hat, the brown surtout the same;
His bristling beard just rising in its might,
'Twas four long days and nights to shaving-night;
His uncomb'd grizzly locks, wild staring, thatch'd
A head for thought profound and clear unmatch'd;
And though his caustic wit was biting, rude,
His heart was warm, benevolent, and good. (x.)

SMELLING is the act by which we perceive smells, or become sensible of the presence of odorous bodies. The sensations of smell are excited by certain effluvia, which, in the open air, are always issuing from the surfaces of most bodies, and striking on the extremities of the olfactory nerves, give them a peculiar sort of impression, which is communicated to the brain. The particles which issue thus from bodies are extremely volatile, and produce sensation by a degree of contact, which, though insensible, is still more efficient than if it were more gross and palpable. It is by a similar species of insensible contact that the eyes and ears are affected by external objects; while, in the excitation of the sensations of touch and of taste, an actual and sensible contact of the object with the organ is necessary. The organs of smelling are the nostrils and olfactory nerves; the minute ramifications of the latter being distributed throughout the whole concavity of the former.

The effluvia from odorous bodies are constantly floating about in the atmosphere, and must of course be drawn into the nostrils along with the air in inspiration; "so that there is," as Dr. Smith observes, "a manifest appearance of design in placing the organ of smell in the inside of that canal through which the air is continually passing in inspiration and expiration." It has been affirmed by Boerhaave, that the matter in animals, vegetables, fossils, and the like, which chiefly affects the sense of smelling, is that attenuated substance, inherent in their oily parts, called *spirits;* because, when this is taken away from the most fragrant bodies, what remains has scarcely any smell at all; but this, he says, if poured on the most inodorous bodies, gives them a fragrancy.[1] We cannot however enter at present upon this inquiry.

The sense of smell has a close alliance with that of taste; and it seems probable from the proximity in the situation of their organs in all animals, that both are principally intended to guide them in the choice of their food; so that from this close connection, they are better enabled to choose what is good for them, and to reject what would be injurious. This is the opinion of Dr. Reid, as it was, in a very early period of the history of philosophy, that of Socrates and of Cicero.[2] Dr. Reid also remarks, that the sense of smell probably serves the same purpose in the natural state of man; but it is not always a sure guide for this purpose. The organs of smell differ, like those of the other senses, according to the destination of the animals to which they belong; and we know, that this sense is in man much less acute, than in many other animals. We see, that in the choice of their food, they are guided by the senses of smell and of taste, except when man has brought them into a sort of unnatural state by domestication. And this circumstance renders it probable, that both these senses were intended to serve the same purpose in the natural state of our species, although less calculated for this end than they were in the brutes, on account of the great superiority of their smelling organs. Besides, since it is probable that man, in the natural state, acts more by instinct than when civilized in society, so also it is reasonable to think, that he may possess some of the senses, this of smell for instance, in greater acuteness than we do. This indeed we are assured to be a fact; for we are told in the *Histoire des Antilles*, that there are negroes who, by the smell alone, can distinguish the footsteps of a Frenchman from those of a negro.

The sense of smell is much more obtuse in man than in some of the lower animals. Dogs we know possess a power of smelling, of which we can scarcely form a conception, and which it is happy for us we do not possess;[3] and birds of prey are said to possess this sense in still greater acuteness. But although this be more perfect, still the sense of smelling in man, who has other means of judging of his food, is such as to fit him for deriving enjoyment from a diversity of scents, particularly those of flowers and perfumes, to which dogs and other animals seem perfectly insensible. It has been said, we are aware, that some animals, the elephant for instance, are capable of this enjoyment;[4] but of this fact we cannot help being very doubtful.

There is a very great sympathy between the organs of smell and of taste; for any defect or disease of one is generally attended with some corresponding defect or disease of the other. There is also a greater similarity between the sensations of both these, than between those of any other two senses; and hence it is, that we can sometimes tell the taste of an object from its smell, and *vice versa.* Hence also the reason why we apply the same epithets to the names of both these classes of sensations; as a sweet smell or taste.

It deserves also to be remarked, that both these senses seem subservient to the preservation of the animal existence, rather than to any other purpose. They accordingly constitute an object of the natural history of man, rather than of intellectual or of moral philosophy. The other three senses, on the contrary, seem rather intended for, as they certainly are essential to, our intellectual improvement, and become, of course, a proper object of investigation in the sciences of moral philosophy, or metaphysics.

The advantages derived by man and the other animals from the sense of smelling are not confined to the assistance which it affords them in the choice of their food. Most bodies in nature, when exposed to the open air, are constantly sending forth emanations or effluvia of such extreme minuteness as to be perfectly invisible. These diffuse themselves through the air, and however noxious or salutary, would not be perceived without the sense of smelling, which, if not vitiated by unnatural habits, is not only a faithful monitor when danger is at hand, but conveys to us likewise the most exquisite pleasures. The fragrance of a rose, and of many other flowers, is not only pleasant, but gives a refreshing and delightful stimulus to the whole system, while the odours proceeding from hemlock, or any noxious vegetable, or other substance, are highly offensive to our nostrils. Hence we are naturally led to seek the one class of sensations, and to avoid the other.

In some species of animals the sense of smell seems to be connected with certain mental sympathies, as those of hearing and sight are in all that possess them in any high degree; for not only their sexual desires appear to be excited by means of it, but other instinctive passions, which, according to the usual system of nature, should be still more remote from its influence. Dogs, although wholly unacquainted with lions, will shudder at their roar; and an elephant that has never seen a tiger, will in the same manner show the strongest symptoms of horror and affright at the smell of it. "The late Lord Clive," says an ingenious writer, "exhibited a combat between two of these animals at Calcutta; but the scent of the tiger had such an effect upon the elephant, that nothing could either force or allure him to go along the road, where the cage in which the tiger was inclosed, had passed, until a gallon of arrack was given him. Upon this, his horror suddenly turning into fury, he broke down the paling to get at his enemy, and killed him without difficulty."

[2] "Ut gustus," says a learned physiologist, "cibi itineri, sic olfactus ostio viarum, quas aer subire debet, custos præponitur, moniturus ne quid noxii, via quæ semper patet, in corpus admittatur. Porro, ut gustus, sic quoque olfactus ad salutarem cibum invitat, a noxio aut corrupto, putrido imprimis vel rancido, deterret."

"When thou seest the mouth, through which animals take in whatever they desire, always placed near the nose and eyes, thinkest thou not, say Socrates to Aristodemus, that this is the work of a providence." (Xenophon's Memorabilia, book i. chap. 4.)

[3] "The excessive eagerness which dogs express on smelling their game, seems to be but little connected with the appetite for food, and wholly independent of any preconceived ideas of the objects of their pursuit being fit for it. Hence several kinds of them will not eat the game which they pursue with such wild impetuosity; and of which the scent seems to animate them to a degree of ecstacy far beyond what the desire of food can produce." (Knight on Taste.)

[4] There is an animal to which, naturalists say, perfume is so agreeable and so necessary, that nature has provided it with a little bag stored with an exquisite odour. "On pretend," says Buffon, "que la mangouste ouvre cette poche, pour se refraichir lorsqu' elle a trop chaud."

If riding along a road, near which a dead horse, or part of its carcass, happens to be lying, we know, that our horse although he sees it not, cannot be made to pass the place but with difficulty. Where blood has been shed, particularly that of their own species, oxen will assemble, and upon smelling it, roar and bellow, and show the most manifest signs of horror and distress; and yet these symptoms could not arise from any associated notions of danger or death, since they appear in such as never had any opportunities of acquiring them. They must therefore be instinctive like other instinctive antipathies and propensities. But although in their mutual intercourse, animals make much use of the sense of smell, still it does not seem to be further concerned in exciting their sexual desires, than in indicating their object.

Some of those splenetic philosophers, who are ready upon all occasions to quarrel with the constitution of nature, have taken the liberty of condemning their Maker, because it has pleased his unfathomable wisdom to bestow in some instances upon the brutes senses and instincts more perfect than he has given to man, without reflecting that he has given to man an ample equivalent; for it may be asked with the poet,

> Is not his reason all these powers in one?
> Is Heaven unkind to man and man alone?
> Shall be alone, whom rational we call,
> Be pleased with nothing if not blessed with all?

With respect to that unknown peculiarity of bodies, which is the cause of our sensations of smell, the opinions of philosophers have been very various. Until of late, the doctrine of Des Cartes and Locke on this subject was pretty generally received; but, since the publication of Dr. Reid's works, his opinion, which we deem the most correct and satisfactory, has become very popular. We will endeavour to abridge his account of this matter. For this purpose, let us suppose a person, who has grown up without the sense of smell, to be immediately endowed with the use of this organ, and placed near some flowers of an exquisite savour. When he examines what he feels in such a situation, he can find no resemblance between this new sensation, and any thing with which he is already acquainted. He finds himself unable to explain its nature, and cannot ascribe to it figure, extension, or any known property of matter. It is a simple affection, or feeling of mind, and, considered abstractedly, can have no necessary connection with the nerves, the nostrils, or effluvia, or with any thing material whatever. By the nature of his constitution he is however led to refer this peculiar sensation to the nostrils, as its organ; and when, from experience, and by means of touch, he learns that external objects have the power of exciting this sensation, he concludes, that there must exist in bodies some unknown cause by which it is excited. In the first part of this process he considers the feeling, or sensation, abstractedly. As such, it exists in the mind only; and cannot exist there but when the mind is conscious of it. His consciousness soon enables him to distinguish different sorts of smells, all of them very distinct from one another, but, conformably to the nature of all sensation, extremely simple. He concludes, that each of these must have a distinct cause; and finding, by experience, that this cause is an unknown something in bodies, he concludes, that it must be a property of matter, and, for want of another, gives it the name of smell. When he removes an odorous body from the organ, the sensation vanishes; when the body is again applied, the sensation is excited; and hence it is, that he is led naturally to connect the sensation with this unknown peculiarity of bodies by which it is produced. But since we see, that the sensation is, in a great degree, related to other objects besides its unknown cause, to the mind in which it exists, for instance, and to the organ which is its instrument, it may be asked why it becomes associated in the mind with its cause only? The reason seems pretty obvious. No single sensation, or class of sensations, is more connected with the mind, than any other of which it is susceptible. Nor is the connection subsisting between the organ and any of the sensations peculiar to it, greater than that which subsists between it and every other sensation of which it is the inlet. Hence the connection between the smell of an orange and the mind, or between it and the nostrils, is very general, and cannot, in the former instance, distinguish it from any other sensation of whatever kind, nor, in the latter, from any other particular smell. But the connection between this sensation and the orange is peculiar and permanent; and we accordingly find them always associated in the mind, just as we associate the notion of fire with the sensation of burning. The relation which a sensation of smell, or any sensation, bears to the mind, to an organ, or to the memory and conception of itself, is common to all sensations. The relation which any sensation bears to its own cause, suppose of the sensation of smell to a particular virtue or quality of bodies, is common to it with every other sensation, when considered with respect to its peculiar cause. And finally, a sensation of any kind bears the same sort of relation to the memory and conception of itself, that any other feeling or operation of mind bears to the conception and memory of that particular feeling or operation.

Whatever then be the nature of the minute particles of bodies by which our sensations of smell are excited, we cannot help considering their unknown cause as a virtue or quality of matter. Like all other modifications of material substance, it must be confessed, that this can have no resemblance to the sensations of mind. But we are not therefore to conclude with the followers of Des Cartes and Locke, that this secondary quality is a mere sensation; especially as we can readily conceive it existing where it is not smelled, or even after supposing the annihilation of every sentient being throughout the universe. The existence of the sensation we know to be momentary and fugitive; but in the existence of its cause we can, without difficulty or inconsistency, conceive a permanency independent of mind and of its sensations.

The doctrine which we have been illustrating has of late been called in question by a sceptical writer, who, it appears to us, has upon this occasion been entirely deficient in his accustomed acuteness. Dr. Reid's speculations seem so full, so clear and convincing, that we are at a loss to conceive how his meaning can be misunderstood; and yet the argument and objections of the writer to whom we allude, derive all their plausibility from a misinterpretation of Dr. Reid's meaning, and from a deviation from the established use of language. "An eminent metaphysician," says this author, "has declared that he has not the least difficulty in conceiving the air perfumed with aromatic odours in the deserts of Arabia; and he has decided, that the man who maintains smells to exist only in the mind must be mad, or must abuse language and disgrace philosophy. There are some authors, nevertheless, who differ widely on this subject from the learned metaphysician. Is it possible for a sensation to exist where there is no sentient? The authors to whom I allude think it impossible." And so, we may tell this learned author, does Dr. Reid, if he will take his word for it. Of the sensation of smell he remarks, "It

Smelling.

is indeed impossible, that it can be in any body; it is a sensation, and a sensation can be in a sentient thing only."[1] Again, "I can think of the smell of a rose when I do not smell it; and it is possible that when I think of it, there is no rose any where existing; but, when I smell it, I am necessarily determined to believe that the sensation really exists. This is common to all sensations, that, as they cannot exist but in being perceived, so they cannot be perceived but they must exist."[2] But, continues this acute metaphysician, "a smell is nothing else than a sensation. It is a feeling, which may be agreeable or disagreeable; which may, as some think, be excited by various combinations of elements; but which, since it is a feeling, cannot be those elements which are said to cause it, and cannot exist where there is no creature to perceive it. What is to be understood, in philosophical strictness, by the perfumes of the desert? We can excuse the poet when he makes the ocean smile,[3] the winds dance,[4] and the flowers respire;[5] or even were he to perfume the desert. But the philosopher is no such magician, and had better not wander through the regions of fancy in search of sensations where there is no sentient." And is it then true that the word smell means only a sensation? A sensation is no more than an effect; it is a transient modification of the mind, which the mind itself can never produce. It must then have some cause which is external to the mind. Now, it is to this cause, and not to the sensation, that the name smell is most frequently applied in all languages; and it is this cause which Dr. Reid supposes capable of existing in the deserts of Arabia, where there is no sentient being to perceive it. But let us hear himself. "We have considered smell as signifying a sensation, feeling, or impression upon the mind; and in this sense it can only be in a mind or sentient being; but it is evident that mankind give the name of smell much more frequently to something which they conceive to be external, and to be a quality of body; they understand by it something which does not at all infer a mind, and have not the least difficulty in conceiving the air perfumed with aromatic odours in the deserts of Arabia, or some uninhabited island where the human foot never trod."[6] "The faculty of smelling is something very different from the actual sensation of smelling; for the faculty may remain when we have no sensation. And the mind is no less different from the faculty, for it continues the same individual being when the faculty is lost. What is smell in the rose? It is a quality or virtue of the rose, or of something proceeding from it, which we perceive by the sense of smelling; and this is all we know of the matter. But what is smelling? It is an act of the mind, but is never imagined to be a quality of the mind. Again, the sensation of smelling is conceived to infer necessarily a mind or sentient being; but smell in the rose infers no such thing. We say, this body smells sweet, and that stinks; but we do not say, this mind smells sweet, and that stinks; therefore smell in the rose, and the sensation which it causes, are not conceived, even by the vulgar, to be things of the same kind, although they have the same name."[7]

There are some other remarks on Dr. Reid's opinion, in the work upon which we have been commenting, which we shall pass by; we may however notice the author's concluding argument. After mentioning some examples, he observes, "Now, in these instances, we see men and animals, that must have perception of smell, if I may be permitted to say so, altogether different from each other. Is not smell sensation when the spaniel finds sport in the field for his master; when the shark pursues through the ocean its expected victim; and when the camel conducts the thirsty wanderer to a fountain of fresh water, across the burning sands of the Arabian desert? If no animal had the sensation of smell, there would be no odour; for aroma and oils may be thought to be material compositions, but are neither agreeable nor disagreeable feelings." If men and animals differ in their perceptions of smell, and, no doubt, difference of organization will cause them to do so, the conclusion should not be, we think, that smell is merely sensation, but that there is actually something external which is the cause of their sensations, and about which they differ. A rose put to the nostrils of a man, and then to those of a dog, may excite very different sensations; but we cannot think that the peculiarity of the rose, which excites those different sensations, varies by thus changing the position of the rose. If at table one person mistakes mutton for beef, and another thinks that it is venison, the conclusion may be, that it is neither venison nor beef; but no man in his senses, can conclude that there is no meat at the table. But, "is not smell sensation when the spaniel finds sport in the field?" There is sensation no doubt; but we may be permitted to ask, what would become of the spaniel's sensation of smell and of his master's sport, were there no game in the field? What of the shark's sensation of smell and pursuit, were there no victim in the ocean? and what of the camel and the thirsty wanderer, were there no fountain of fresh water in the Arabian desert? "The smell of a rose signifies two things," says Dr. Reid; "first, a sensation which can have no existence but when it is perceived, and can only be in a sentient being or mind; secondly, it signifies some power, quality, or virtue in the rose, or in effluvia proceeding from it, which hath a permanent existence independent of the mind, and which, by the constitution of nature, produces the sensation in us. By the original constitution of our nature, we are both led to believe that there is a permanent cause of the sensation, and prompted to seek after it; and experience determines us to place it in the rose. The names of all smells, tastes, sounds, as well as heat and cold, have a like ambiguity in all languages; but it deserves our attention, that these names are but rarely, in common language, used to signify the sensations; for the most part, they signify the external qualities which are indicated by the sensations."[8] We have been induced thus to discuss this topic at some length, because we regretted to see Dr. Reid's opinion and reasoning misrepresented; and we shall now conclude, not as this modern Berkleian does, "that if no animal had the sensation of smell, there would be no odour," but, that if there were no odour or external cause of smell, no animal would have this sensation.

Smelt by ho blast

Recen change the pr of man facturi iron.

SMELTING IRON by HOT-BLAST. Since the article on the MANUFACTURE OF IRON was published in the usual order of the progress of this work, certain changes have been introduced in the process of making iron, of so extensive and important a character, that we cannot consider them in any other light than as effecting an entire revolution in those branches of industry and of commerce connected with the manufacture and application of that most valuable of metals. The change has been comparatively unnoticed, extending itself during the last ten years, from the little spot in a remote part of this island whence it took its origin, and has now found its way over a great part of the old world, and been adopted extensively in the new. Wherever it has found its way, wealth and prosperity have attended it, poverty and sterility have fled before it; and there have been opened up vast stores of mineral wealth to assist in the advancement of civilization and industry, which our former impotence and want of skill had marked with the stigma of utter unproductiveness. It is therefore necessary that we give in this article, as supplementary to our former treatise, an account of the new process, now well known over the whole manufacturing world as the *hot-blast process* for smelting iron.

Smelting by hot-blast.

The hot-blast process was invented in Scotland by Mr. James Beaumont Neilson, a practical engineer at Glasgow, and was by him made the subject of a patent, dated September 1828, being entitled, an "improved application of air, to produce heat in fires, forges, and furnaces, where bellows and other blowing apparatus are required."

The invention of Mr. Neilson, like a great many other inventions, and indeed some of the most valuable, is characterized by extreme simplicity; and his invention so perfectly accords with all the known laws of physics, that we at once apply to it the well known exclamation of wonder, "how strange! that a thing so obvious should not have been done long before!" an exclamation in which we too often find ourselves doing an act of injustice to the very inventors to whom we lie under the weightiest obligations. Mr. Neilson's hot blast is as simple a contrivance as was the steam-engine condenser of his countryman, Mr. Watt, and indeed bears a very close analogy to its character as an invention. Before the time of Mr. Watt, steam was introduced into that part of the steam-engine where it performed its labour, and was then condensed into water in the same place where it had done its duty, thereby causing great waste of fuel and loss of power; and to remedy this defect, Watt introduced his new principle on which his fame rests; he used a *separate condenser*, that is, cooled the steam, and reconverted it into water, not in the cylinder, where it was detrimental, but in a separate vessel communicating with it. In like manner, Mr. Neilson's invention consists in separately heating that which was formerly done so as to be injurious to the process intended. Cold air was blown into a furnace designed to produce intense heat for the smelting of iron from ore, so that the cold blast of air itself required to be heated by the fuel in the furnace intended to smelt the iron, and so its temperature was cooled down by the very intensity of the blast required for the desired combustion. To remedy this defect, Mr. Neilson introduced his new principle of hot blast; and instead of allowing this blast of cold air to enter at once from the blowing machine or bellows into the furnace, to be heated there, he provided a *separate heating apparatus*, by which the air of the blast was to be heated by a separate furnace and fire, previously to its entrance into the smelting furnace. This is the whole invention. A hot blast of air, instead of a cold one, is thus introduced for the generation of heat. Could any thing be more simple, more natural, more appropriate, or more likely to prove effectual? This is the hot blast, which has already in this and other countries created many millions of valuable property out of what was formerly worthless, because unavailable by any of the processes formerly known.

Like most other inventions, the progress of this was at first very slow. Retarded by practical difficulties, which beset all new processes in their first use, by men who have every thing to learn,—stopped every now and then by the prejudices of custom and ignorance, which cling with inveterate tenacity to maxims of established practice, and repel equally the innovations which improve and those which merely alter without improvement,—opposed also by the change of interests which such a revolution must necessarily involve; the invention, tardy in its first steps, and feeble in its early efforts, was more than once at the point of being altogether abandoned. Like the invention of Watt, a great part of the interest in its possible remuneration was transferred by the inventor to strangers, whose combined efforts and influence it was necessary to obtain on the side of the innovation. To Mr. Dunlop of Clyde iron-works Mr. Neilson had to give up three-tenths of his patent rights; to Mr. Mackintosh three-tenths; and one-tenth to Mr. Wilson of Dundivan, retaining to himself only three-tenths of this valuable monopoly. But the transfer was judicious; it was necessary. Mr. Mackintosh is distinguished as a man of much practical science; Mr. Dunlop was one of the most sagacious iron-masters of his time; and Mr. Wilson was a man of tried practical talent. The co-operation of these gentlemen was essential to the speedy and successful trial of the novel though simple process.

Specification of the hot-blast patent.

The following is the specification of Mr. Neilson's patent: "I, James Beaumont Neilson, do hereby declare, that the nature of my said invention for the improved application of air to produce heat in fires, forges, and furnaces, where bellows or other blowing apparatus are required, and the manner in which the same is to be performed are particularly described and ascertained as follows: That is to say, a blast or current of air must be produced by bellows or other blowing apparatus in the ordinary way, to which mode of producing the blast or current of air this patent is not intended to extend. The blast or current of air so produced is to be passed *from the bellows or blowing apparatus into an air vessel or receptacle, made sufficiently strong to endure the blast, and through and from that vessel or receptacle, by means of a tube, pipe, or aperture into the fire, forge, or furnace.* The air vessel or receptacle must be air-tight, or nearly so, except the apertures for the admission and emission of the air; and at the commencement, and during the continuance of the blast, it must be kept *artificially heated to a considerable temperature.*

"It is better that the temperature be kept to a red heat, or nearly so; but so high a temperature is not absolutely necessary to produce a beneficial effect. The air-vessel or receptacle may be conveniently made of iron; but as the effect does not depend upon the nature of the material, other metals or convenient materials may be used. The size of the air vessel must depend upon the blast, and on the heat necessary to be produced. For an ordinary smith's fire or forge, an air vessel or receptacle, capable of containing 1200 cubic inches, will be of proper dimensions; and for a cupola of the usual size for cast-iron founders, an air-vessel capable of containing 10,000 cubic inches will be of a proper size. For fires, forges, or furnaces, upon a greater scale, such as blast-furnaces for smelting iron, and large cast-iron founders' cupolas, air-vessels of proportionably increased dimensions and numbers are to be employed. The form or shape of the vessel or receptacle is immaterial to the effect, and may be adapted to the local circumstances or situation. The air-vessel may generally be conveniently heated by a fire, distinct from the fire to be affected by the blast or current of air, and generally it will be better that the air-vessels and the fire by which it is heated should be inclosed in brick-work or masonry, through which the pipes or tubes connected with the air-vessel should pass. The manner of applying the heat to the air-vessel is, however, immaterial to the effect if it be kept at a proper temperature. In witness whereof, I, the said James Beaumont Neilson, have hereunto set my hand and seal, the 28th day of February, in the year of our Lord 1829."

Manner of using the hot-blast.

The only part of the process of smelting the iron which is at all affected by this novelty, is the transit of the air from the blowing machinery into the smelting furnace. The bellows, steam-engine, water-wheel, blowing cylinders, equalizing reservoirs, or other apparatus of whatever sort, for producing the current of air to blow the fire, are left unchanged, as we have already described and figured them in our article on IRON. The furnace may be left of its former shape and dimensions in every respect as used in the old process, and as we formerly described them; all that is required for the introduction of the new process, is to interpose between the smelting furnace and the blowing machinery an oven, heated by a separate fire, through which, in appropriately shaped vessels or pipes, the blast of air on its way to the furnace may be heated to a considerable temperature,—400°, 600°, or any temperature found most suitable to the purpose, and so blown upon the incandescent fuel in the furnace in a hot blast, as distinguished from the ordinary cold blast of atmospheric air.

The consequences of this hot blast system in an economic point of view, may be illustrated by the following experimental facts.

Advantages of the hot-blast system.

In a given furnace in Scotland, previous to the introduction of the new process, the following was the average result obtained:

20 tons of coal (coked),
with $3\frac{1}{2}$ tons of limestone,
smelted $4\frac{1}{2}$ tons of iron,
being $3\frac{1}{2}$ tons of fuel to each ton of iron.

In the same furnace, by the introduction of the new process, the result was as follows:

14 tons of coal (raw),
with $2\frac{1}{4}$ tons of lime,
smelted 8 tons of iron,
being $1\frac{3}{4}$ tons of fuel to each ton of iron.

Here, then, we see that, in the first place, one half of the fuel only is required; that coking, a very expensive process, is avoided, the coal being used raw, which was formerly impossible; and that only about one-third of the quantity of limestone is required to flux the iron, and all the cost of these materials, and all the labour employed in their transport, and in the process of melting, are clearly saved. But these were not the only benefits conferred on the iron-master. The same furnace, blowing apparatus, and establishment, that formerly produced fifty tons a-week, yielded under the hot blast more than double that quantity.

Peculiar advantage of the hot-blast in Scotland.

As it was in Scotland that these advantages were first obtained, so it is there that they are still possessed in the highest degree. Previously to the introduction of the hot blast, it had become an almost hopeless competition to produce iron there at so cheap a rate as the Welsh iron-masters could import it into Scotland. The hot blast at once turned the scale; and Scotland now transmits annually many thousand tons of iron to all the markets of England, and even into the very heart of the iron districts of the principality itself.

The cause of this difference between the advantage which Wales has derived from the hot-blast process, and that conferred on Scotland, is simply this: the coal fields of Wales are a rich, strong, and highly carbonaceous fuel, which loses not more than thirty to forty per cent. in the process of coking. The coal basin of Scotland in the iron district is, on the contrary, of a poor, earthy, light description, so as to lose from fifty to sixty per cent. in the process of coking, and giving, for every two tons of coal, not more, and frequently much less, than one ton of coked fuel fit for the cold-blast smelting-furnace. The expense and loss in the Scotish coal by this preparatory process of coking, was therefore excessive, when compared with the Welsh coal; and hence the adoption of this new plan, which did not require this preliminary process of coking, became a much greater boon to the Scotchman, in exact proportion to his former disadvantage.

Result in Staffordshire.

Great as these advantages have been found in Scotland, they have by no means been limited to the country of the inventor. In Staffordshire, in the wonderfully rich mineral basins of Dudley, and in Derbyshire, the invention was very early introduced, and most successfully practised. The following are the general results of the hot-blast system, as now practised in Staffordshire, in comparison with the old system:

By the cold blast,
8 tons of coal (coked),
with $1\frac{1}{10}$ ton of lime,
yielded 3 tons of iron,
being $2\frac{2}{3}$ tons of fuel to each ton of iron.
By the hot blast, in 1840,
$2\frac{1}{2}$ tons of coal (raw),
with $\frac{6}{10}$ths of a ton of limestone,
yield $2\frac{1}{2}$ tons of iron,
being 1 ton of fuel to each ton of iron.

Hot-blast admits the use of inferior materials.

The saving thus obtained in the article of fuel, is accompanied, it will be noticed, in every instance, with a corresponding saving in the limestone employed to flux the metal. But even here the whole amount of advantage does not meet the eye. It was formerly important to use the very best quality of coal that could be obtained,—light, bituminous, or earthy coal, being least fit for the purpose, and most unprofitable. Now, although it is still desirable to have a better rather than a worse fuel, the importance of this point is so greatly diminished, that almost all the inferior descriptions of poorer and more bituminous coal may be employed with economy and advantage. Limestone of the best quality was essential to the produce of good iron by the old method; by the new method, it is obvious, from inspection of the examples given, that the saving in limestone varies from a third to two-thirds of the quantity employed; but, in addition to this, it has become practicable to employ limestone of a very inferior quality, where better may be scarce, without sensible deterioration of the metal.

For the production of good iron, the hot-blast system has thus opened vast resources, which formerly could not be rendered available, in consequence of the inferior quality of some one of the raw materials which could be brought together in a given locality. In one place, abundant in excellent carbonate of lime and rich ore, it became impossible to realise the mineral wealth, on account of the inferior quality of the coal; while, in another, an abundant supply of good limestone, and of good coal, could not be used with advantage, from the poverty of the ore, which happened to be a clay stone, containing a small proportion of iron. Perhaps, also, a portion of sulphur mixed with the materials in such a quantity, as to ruin the iron. These all are counterbalanced by the hot blast, and every one of these impracticable cases is now exemplified in daily use.

But there is no sphere in which the hot blast has exerted a more beneficial influence in promoting the success of industry, and extending the resources of civilization, than in its application to those sterile districts of the mineral world, known as the region of the stone coal, blind coal, or anthracite formation. In the blind or stone coal strata, we have that most valuable of all combustibles, carbon, in a condition of high density and purity, amounting to as much as ninety or ninety-five per cent. of the stone coal, with a very small per centage of earthy or hydrogenous matter, yet so contracted, and, as it were, iron-bound, so hard and obdurate, that, instead of forming a good combustible, it seems to partake of the nature of that wonderful and brilliant substance, so hard of combustion as to have been reckoned one of the incombustibles until the glass of the accomplished analyst resolved the glittering brilliant into its primitive carbon. The anthracite seems, in fact, truly to deserve the name of the "black diamond," having been rendered, by its dense and close structure, nearly as incombustible. Although America, and many wide districts of Europe, abound with this rich carbon, it has failed to furnish, even in the hands of many accomplished chemists and mechanicians, an available fuel, either for the generation of steam, or for the ordinary wants of social life, and has resisted even the intense heat of the blast furnace. But even its consummate obstinacy has yielded to the power of the hot blast. In Wales, and in America, hot-blast iron of the very finest quality is now made from stone coal; and thus stores of the richest fuel which the world contains, appear only to have been reserved, by their wonderful obduracy, from the rapid destruction to which all other fuel has been so wastefully subjected, to supply the civilization and science of the nineteenth century with the means of rewarding and extending its astonishing discoveries. So kindly has Providence placed at the surface of the earth one mineral fuel to replace the forests which supplied the fires of our forefathers, and deposited another still richer, but more remote in the bowels of the earth, to await and to reward the industry and research of their children and our own. What geologist will henceforth call in question the abundance of that supply, which now seems to augment with the very means that are invented for increasing its consumption?

V e of th ot- bl in W h an- th te di ict,

The Welsh coal-field is perhaps the richest in the world. Rich with bitumen on one side, it gradually falls off by insensible gradations into a more purely carbonaceous, but still free-burning coal, and, passing through every intermediate gradation, is found at last in the state of a rich, resplendent refractory anthractous, or stony coal. This, mixed in the proportion of two to three, three to two, or half and half, smelts iron readily under the hot blast, and produces a rich powerful pig, possessing the qualities of a rich charcoal iron, and also capable of being converted into a most tenacious and malleable bar iron. In the anthracite district of Wales, new furnaces are rapidly rising into use; and Mr. Crane is distinguished by his extensive use of Mr. Neilson's hot-blast in that application of it.

ar in the ar racite di ict of A erica.

But it is probably in America that the hot-blast system will most extensively contribute to the development of mineral wealth. The anthracite is there the staple of fuel. It covers a vast extent of country, and constitutes the only substitute with which our transatlantic brethren can replace those forests that are so rapidly receding before the advances of civilization. Here the hot-blast is most successfully employed.

D ription of he hot- bl appa- ra .

We have thus given our readers the general specification of the hot-blast improvement; a specification so general as to include all possible forms of apparatus, applicable, not only to the smelting of iron, but to all cases of manufacture in which a blast is employed to produce heat, and which touches only the process of heating the air, without regard either to the mode of producing the blast, the mode of applying the blast, or the means of heating air; and the patent only provides for the carrying into effect the process of heating the air, that the blast shall be passed through a heated vessel or receptacle of any form or dimensions, such as a cast or malleable iron retort, kept to a dull red heat of some 1000° of temperature as the most desirable. It will readily be imagined that this apparatus, described in terms of so great generality, would assume various forms, according to the different views which the various practical men employed to construct the apparatus took of the most effective mode of heating the air. This is accordingly what occurred with the progress of time, and the increasing experience of those who used the apparatus; practical difficulties gradually diminished with the increased experience which was every day suggesting new and better expedients. It was also soon found that the advantage gained was increased in a rapid proportion with the degree of heat communicated to the air, so that the apparatus which gave at first some 300° of temperature to the air, and produced one measure of benefit, was soon superseded by a second form of apparatus giving 400°, and conferring still higher advantages; and this in its turn gave way to another and another, each giving a higher temperature to the air, and promising a higher degree of economy to the user. And thus at last a temperature between 600° and 700° was given to the air; a temperature higher than that of melting lead, which is indeed the criterion now generally applied to test the working heat of the blast.

P ess of im ve- me exhi bit in the Bu rly iro vorks.

We shall probably give our readers the clearest views of these general improvements, and of the progress which has generally taken place in carrying them into effect, by taking a single example. For this purpose we have selected the various modes of heating the air that have necessarily suggested themselves to, or been put in practice by the ingenious proprietors of the Butterly iron-works in Derbyshire, who were the first to introduce the hot-blast into that part of the country, and who have been among the most successful in carrying it into effect, and producing one of the most superior qualities of hot-blast iron.

Plate CCCCLXII. fig. 1, shows the construction of the earliest and simplest plan by which the inventors of hot-blast first brought it into use. An iron vessel *hhh* was formed of malleable plates, rivetted together like a common steam-boiler, something near three feet in diameter, and eight or ten feet long, cylindrical, and fitted at the ends to two pipes B*b*, communicating with the bellows, and S*s* with the smelting furnace. Below this large pipe or tube a fire is placed, which is fed from the door D, and the whole is enclosed in an oven of brickwork OOOO, leaving a clear space all round the pipe *hhh*, so that the flame and hot air rising up and enveloping the receptacle, should keep it so hot as to communicate through the sides of the vessel a higher temperature to the air rushing through it, on its way from the bellows, B, towards the smelting furnace S. And in order to communicate this temperature more uniformly and completely to all the air passing through the vessel *hhh*, lunular partitions *ppp* proceeding alternately from opposite sides of the tube on its interior surface, cause the stream of air to impinge first on one side, and then on the other side of the heated iron pipe, as shown in the figure. By this apparatus a moderate current of air has been heated to three or four hundred degrees.

First apparatus.

Fig. 2 shows the manner in which the method of heating the air was employed at first in the Butterly ironworks. In the oven O O are placed the two cast-iron retorts *hh*, about thirty-two inches in diameter, and nine feet long, being of metal an inch and an eighth part in thickness. They are laid parallel to each other; one of them is at one end connected with the pipe B *b* from the blowing apparatus, and this conducts the air from its other extremity through a curved junction pipe JJ, into the second receptacle *hh*; where, on its way becoming hot, it passes through the hot-air pipe S *s*, from the heating furnace or oven, and is blown by the orifice T through the twyre T into the hearth of the smelting furnace at F. In this, as is usual, more than one blast, as at T', was blown into the same smelting furnace. The fire *dd*, is placed at one corner of the oven on the bars *rr*, and is fed from the door D, and the smoke and flame rising up and surrounding h^1h^1, pass through a partition by the flue *f*, and fill the second compartment of the oven, clear spaces being left quite round the retorts on every side for the communication of the heat; only at the points *k* and *k*, they are supported by contact on the brick pillars *kk*. Finally, the products of combustion pass through a flue *f* into the short chimney C. In this way the cold air from the blast pipe B*b* passing into the vessel h^2 h^2, is partially heated, and is conducted into a second chamber, which, being placed immediately over the fire, is much more intensely hot, and from this second chamber at once discharged into the smelting furnace.

Its effects.

This apparatus was first tried in November 1830. The air was only heated to 240°. Yet so admirable is the process, that it was attended with the following effect:

With cold blast there were previously used at Butterly,
$5\frac{1}{2}$ tons coal (coked),
to 1 ton of iron.
By the new apparatus there were required
only 3 tons coal (raw),
to 1 ton of iron.

So admirable an effect as this was not to be neglected on account of the practical difficulties attending it, which indeed only served as an inducement to further exertion; and in about a year after the following improved apparatus, with an increased number of tubular vessels, having increased dimensions of length, was successfully introduced.

Second apparatus.

Fig. 3. In the transverse section h^1 h^2 h^3, are three pipes of cast-iron $1\frac{1}{2}$ inch thick, being about 17 feet long, and about 22 inches in diameter. They are similarly denoted in the ground plan, and in the longitudinal section by the letters $h^1h^2h^3$. The cold air pipe from the blowing apparatus B, enters the heating oven at *b* and traverses the pipe h^1 h^1 to the opposite end of the furnace: here a

Smelting by hot-blast.

bent pipe $h^1 h^2$ conveys the air into a second longitudinal pipe $h^2 h^2$, by which the stream of air returns back to the end of the oven at which it entered, and is conducted by a second bent pipe $h^2 h^3$ into the third tubular vessel $h^3 h^3$ in which it is for the last time exposed to the heated metal, and passes off from the heating oven into the smelting furnace, by the hot air pipe S, whence, as formerly, it is discharged through the twyre into the hearth of the furnace. The fuel is placed through the door D upon the fire of the oven on the bars *r*, and by means of a number of small pigeon holes *ccc*, *ccc*, *ccc*, is spread over the whole length of the pipes with some measure of uniformity, whereas, if allowed to act directly on the retorts, it would irregularly and less effectually heat their surface. The manner of protecting the retorts from the direct action of the fire, is well shown in the transverse section: a brick arch *aaa* is thrown over the fire, and the flame is only permitted to ascend through the aforesaid openings *cc*, *cc*. It will be noticed that the retorts are every where clear of the building and of each other, that they are wholly enclosed by the oven O O O; and it will also be seen in the transverse section, and in the longitudinal section, that the products of combustion are carried off by a descending flue *ff*, regulated by a damper *e e*, into the short vertical chimney C. This damper is very useful in retarding the draught of air, so as to leave the products of combustion a longer time in contact with the heaters.

Its effects.

This apparatus is more effective and more durable than the last. It raised the heat of the air as high as 400° to 500°, being 200° higher than the former plan, as indeed we should expect from the greater number and length of the vessels, and the greater surface in contact with the air. The result, compared with the last, is as follows:

By the former plan with air at 240°,
3 tons of coal were required
to melt 1 ton of iron.
By the improved plan, with air at 400° to 500°,
$2\frac{13}{20}$ tons of coal were required
to melt 1 ton of iron.

The reader will not fail to be struck with the fact, that a much greater gain was obtained by the original ruder plan of using the air, when compared with the old system of hot-blast, than was afterwards got from the introduction of the improved apparatus over the former one. The higher temperature does not appear to have conferred an advantage at all proportionable to the increased temperature.

Third apparatus.

Fig. 4 is a very superior and durable heating apparatus, which continues in efficient use to the present time. Its form is well adapted to prevent all the evils of expansion and contraction; and it is our opinion that by multiplying the vessels, a more effective apparatus might be made than any now in use. Its form is very ingenious, and its functions may be easily learned by studying the figure, in which the letters describe the same parts with those of the previous figures. B is the pipe coming from the blowing apparatus to the heating furnace O O O O; S is the hot air pipe, proceeding from the heating oven to the smelting furnace; $h^1 h^1 h^1$ is a large retort into which the air is at first carried, and from the further end of which a malleable iron tube $i^1 i^1$, concentric with the retort, carries it back again to that end where it first entered, and through a bent pipe I I conducts it along by a second interior tube $i^2 i^2$ to the further end of the second heater $h^2 h^2 h^2$, along the hot surface of which it returns in the manner shown by the arrows to the base of the second retort: now, this second retort communicates at the base with a third $h^3 h^3$, and after traversing its heated surface to the end, is brought back by a tube concentric with the axis to the base of the retort. This process might be continued with great advantage, and make one of the best series of heating vessels. The fire is covered by arches *aaa*, with small apertures *ccc*, as in the former case, to prevent the vessels from being injured by the local action of the intense fires.

Smelt by h blast.

Its effec

This apparatus raised the temperature to between 500° and 600°, and produced a further saving in coals. By the former plan $2\frac{13}{20}$ tons of coal were required to smelt one ton of iron. By this improved apparatus, $2\frac{10}{20}$ tons of coal melted a ton of iron.

Fourth fifth ap paratus.

Figs. 5 and 6 are the general forms of apparatus now most extensively used. Fig. 5 is a form first given to the apparatus, we believe, by Mr. Dixon at Calder, and hence generally called the Calder pipes. Similar pipes were also early introduced at Gartsherrie, and at Wedensbury; and are very generally approved of from their extensive heating surface, although they are liable to the inconvenience of cracking, from unequal expansion. The form, as erected at Butterly, consists of two parallel horizontal pipes L L called technically "the lying pipes," one forming a communication immediately with the cold-blast pipe B, and the other with the hot-blast pipe S. Into sockets formed in the lying pipe, are inserted a series of smaller pipes springing up at right angles with the one lying pipe, and after forming an arch, returning down to the second lying pipe, being inserted in like manner into sockets in it. The air, therefore, on entering the first lying pipe, is forced through these transverse heating pipes, or "A pipes" as they are called from their figure, and thus exposed to the heat of a very extensive surface, is delivered into the hot-air pipe. Sometimes, as at Gartsherrie and many other works, there are several times as many pipes as in this example, and the air is made to cross and recross the fire several times.

The figures of the transverse pipes are as various as the taste of the parties who use them. Sometimes they rise up and form a large semicircular arch over the fire, which is placed in the centre; sometimes a double tier of such arches is employed. Sometimes they cross the fire in the form of a pointed arch variously acuminate. Then again by some, the pipes are carried up four, six, eight, or ten feet, like columns, united at the top by a semicircular arch.

The cross section of the heating pipe is as various as the form into which the pipe itself is made to bend. A circular pipe was used at first, then a flattened elliptical one for the purpose of exposing more surface in proportion to volume; next a pipe, flat at one part, and semicircular on the other, was introduced; next a pipe of a cardioïd or heart-like section was employed. At Butterly Mr. Terrop used a circular pipe cast with a solid core, to keep the air near the hot surface, as shown in the figure; and finally, he employed the rectangular section as shown in our figure 6th. All of these appear to answer their purpose of heating the air sufficiently well, and all of them cause trouble and expense by cracking now and then.

The result of all these forms is to produce a hot-blast of more than 600° temperature, and at Butterly, figs. 5 and 6 yield as follows: $2\frac{1}{3}$ tons of coal melt one ton of iron. It is found, however, at Butterly, that pigs, for the forge, require about three cwt. less of coal than this average quantity, and that No. 1 iron requires about three cwt. more than this, as we should expect.

The Scotch use less coal than the Butterly Company, principally on this account, that the former use calcined ore, of which thirty-two cwt. with seven cwt. of lime, makes a ton of iron, while at Butterly, the quantity used for a ton of iron is $2\frac{3}{4}$ tons, with a ton of lime, being $3\frac{3}{4}$ tons of materials in one case, and less than two tons in the other.

Ratio of the cess.

The explanation of the principles from which hot-blast derives its efficacy as the means of producing elevated temperature, is very easy and plain to any one acquainted with the elementary principles of chemistry and mechanics. All that we think it necessary to add on this subject, we shall state in the words of Mr. Babbage and Dr. Ure.

Mr. I bage's planat

> "The increased effect," says Babbage, "produced by thus heating the air is by no means an obvious result; and an analysis of its action will lead to some curious views repecting tbe future application of machinery for blowing furnaces.
>
> "Every cubic foot of atmospheric air, driven into a furnace, con-

S ing
 ot-
 t.

sists of two gases;[1] about one-fifth being oxygen, and four-fifths azote. According to the present state of chemical knowledge, the oxygen alone is effective in producing heat; and the operation of blowing a furnace may be thus analyzed.

"1. The air is forced into the furnace in a condensed state, and, immediately expanding, abstracts heat from the surrounding bodies.

"2. Being itself of moderate temperature, it would, even without expansion, still require heat to raise it to the temperature of the hot substances to which it is to be applied.

"3. On coming into contact with the ignited substances in the furnace, the oxygen unites with them, parting at the same moment with a large portion of its latent heat, and forming compounds which have less specific heat than their separate constituents. Some of these pass up the chimney in a gaseous state, whilst others remain in the form of melted slags, floating on the surface of the iron, which is fused by the heat thus set at liberty.

"4. The effects of the azote are precisely similar to the first and second of those above described; it seems to form no combinations, and contributes nothing, in any stage, to augment the heat.

"The plan, therefore, of heating the air before driving it into the furnace, saves obviously the whole of that heat which the fuel must have supplied in raising it from the temperature of the external air up to that of 600° Fahrenheit; thus rendering the fire more intense, and the glassy slags more fusible, and perhaps also more effectually decomposing the iron ore. The same quantity of fuel, applied at once to the furnace, would only prolong the duration of its heat, not augment its intensity.

"The circumstance of so large a portion of the air[2] driven into furnaces being not merely useless, but acting really as a cooling, instead of a heating, cause, added to so great a waste of mechanical power in condensing it, amounting, in fact, to four-fifths of the whole, clearly shews the defects of the present method, and the want of some better mode of exciting combustion on a large scale."

The reader will find it interesting to compare this account with the following by Dr. Ure.

Dr. res'
exp -
tion

"Wherever a forced stream of air is employed for combustion, the resulting temperature must evidently be impaired by the coldness of the air injected upon the fuel. The heat developed in combustion is distributed into three portions; one is communicated to the remaining fuel, another is communicated to the azote of the atmosphere, and to the volatile products of combustion, and a third to the iron and fluxes, or other surrounding matter to be afterwards dissipated by wider diffusion. This inevitable distribution takes place in such a way, that there is a nearly equal temperature over the whole extent of a fire-place, in which an equal degree of combustion exists.

"We thus perceive that if the air and the coal be very cold, the portions of heat absorbed by them might be very considerable, and sufficient to prevent the resulting temperature from rising to a proper pitch; but if they were very hot they would absorb less caloric, and would leave more to elevate the common temperature. Let us suppose two furnaces charged with burning fuel, into one of which cold air is blown, and into the other hot air, in the same quantity. In the same time, nearly equal quantities of fuel will be consumed with a nearly equal production of heat; but notwithstanding of this, there will not be the same degree of heat in the two furnaces, for the one which receives the hot air will be hotter by all the excess of heat in its air above that of the other, since the former air adds to the heat while the latter abstracts from it. Nor are we to imagine that by injecting a little more cold air into the one furnace, we can raise its temperature to that of the other. With more air indeed we should burn more coals in the same time, and we should produce a greater quantity of heat, but this heat being diffused proportionally among more considerable masses of matter, would not produce a greater temperature; we should have a larger space heated, but not a greater intensity of heat in the same space.

"Thus, according to the physical principles of the production and distribution of heat, fires fed with hot air should, with the same fuel, rise to a higher pitch of temperature than fires fed with common cold air. This consequence is independent of the masses, being as true for a small stove which burns only an ounce of charcoal in a minute, as for a furnace which burns a hundred weight; but the excess of temperature produced by hot air cannot be the same in small fires as in great; because the waste of heat is usually less the more fuel is burned.

Smelting by hot-blast.

"This principle may be rendered still more evident by a numerical illustration. Let us take, for example, a blast furnace, into which 600 cubic feet of air are blown per minute; suppose it to contain no ore but merely coal or coke, and that it has been burning long enough to have arrived at the equilibrium of temperature, and let us see what excess of temperature it would have if blown with air of 300° C. (572° F.) instead of being blown with air at 0° C.

"Six hundred cubic feet of air under the mean temperature and pressure, weigh a little more than 45 pounds avoirdupoise; they contain 10·4 pounds of oxygen, which would burn very nearly 4 pounds of carbon, and disengage 16,000 times as much heat as would raise by one degree cent. the temperature of two pounds of water. These 16,000 portions of heat, produced every minute, will replace 16,000 other portions of heat, dissipated by the sides of the furnace and employed in heating the gases, which escape from its mouth. This must take place in order to establish the assumed equilibrium of caloric.

"If the 45 pounds of air be heated beforehand up to 300° C., they will contain about the eighth part of the heat of the 16,000 disengaged by the combustion, and there will be therefore in the same space one-eighth of heat more, which will be ready to operate upon any bodies within its range, and to heat them one-eighth more. Thus the blast of 300° C. gives a temperature which is nine-eighths of the blast at zero C., or at even the ordinary atmospheric temperature; and as we may reckon at from 2200° to 2700° F. (from 1200° to 1500° C.) the temperature of blast furnaces worked in the common way, we perceive that the hot-air blast produces an increase of temperature equal to from 270° to 360° F.

"Now in order to appreciate the immense effects which this excess of temperature may produce in metallurgic operations, we must consider that often only a few degrees more temperature are required to modify the state of a fusible body, or to determine the play of affinities dormant at lower degrees of heat. Water is solid at 1° under 32° F.; it is liquid at 1° above. Every fusible body has a determinate melting point, a very few degrees above which it is quite fluid, though it may be pasty below it. The same observation applies to ordinary chemical affinities; charcoal, for example, which reduces the greater part of metallic oxides, begins to do so only at a determinate pitch of temperature, under which it is inoperative, but a few degrees above, it is in general lively and complete. It is unnecessary, in this article, to enter into any more details to show the influence of a few degrees of heat, more or less, in a furnace, upon chemical operations, or merely upon physical changes of state.

"These consequences might have been deduced long ago, and industry might thus have been enriched with a new application of science; but philosophers have been and still are too much estranged from the study of the useful arts, and content themselves too much with the minutiæ of the laboratory or theoretic abstractions. Within the space of seven years, the use of the hot-blast has been so much extended in Great Britain, as to have enabled many proprietors of iron-works to add 50 per cent. to their weekly production of metal, to diminish the weekly expenses of smelting by 50 per cent., and, in many cases, to produce a better sort of cast-iron from indifferent materials."

The following table is from a report of M. Dufresnoy, made to the director-general of mines in France in 1834.

Cost of iron by hot-blast.

[1] The accurate proportions are, by measure, oxygen 21, azote 79.

[2] A similar reasoning may be applied to lamps. An argand burner, whether used for consuming oil or gas, admits almost an unlimited quantity of air. It would deserve inquiry, whether a smaller quantity might not produce greater light; and, possibly, a different supply furnish more heat with the same expenditure of fuel.

[3] This mineral is very rich: the average produce of the iron mines of the Glasgow coal basin is 44 per cent. after calcination; in this state it costs from 8s. 6d. to 9s. per ton. The cost of the mineral will, therefore, be very nearly as stated in the table.

Smelting by hot-blast.

Since that period the cost has been rendered much lower, and those who have made good arrangements for mineral property, can manufacture iron at a cost of little more than L.2 per. ton.

Chemical constitution of hot-blast iron.

At the request of the British Association, Dr. Thomson of Glasgow examined the chemical constitution of hot-blast iron, and he gives the following as the result of his inquiry:

"(1.) The specific gravity of hot-blast iron is greater than that of cold-blast.

"The following are the specific gravities of eight specimens of cold blast iron:

1st. Muirkirk	6·410
2nd. Ditto	6·435
3rd. Ditto	6·493
4th. Ditto	6·579
5th. Ditto	6·775
6th. From pyrites	6·9444
7th. From Carron	6·9888
8th. Clyde Iron Works	7·0028

"The specific gravity of the Muirkirk iron is considerably less than of that smelted at Carron and the Clyde Iron-Works; the mean of the eight specimens is 6·7034.

"It has been hitherto supposed that the difference between cast-iron and malleable iron consists in the presence of carbon in the former, and its absence from the latter; in other words, that cast iron is a carburet of iron. But in all the specimens of cast iron which we analysed we constantly found several other ingredients besides iron and carbon. Manganese is pretty generally present in minute quantity, though in one specimen it amounted to no less a quantity than 7 per cent.; its average amount is 2 per cent. *Silicon* is never wanting, though its amount is exceedingly variable, the average quantity is about 1⅕ per cent.; some specimens contained 3⅕ per cent. of it, while others contain less than a half per cent. Aluminum is very rarely altogether absent, though its amount is more variable than that of silicon. Its average amount is 2 per cent.; sometimes it exceeds 4½ per cent., and sometimes it is not quite $\frac{1}{5000}$th part of the weight of the iron.

"Calcium and magnesium are sometimes present, but very rarely, and the quantity does not much exceed ⅕th per cent. In a specimen of cast iron which I got from Mr. Neilson, and which he had smelted from pyrites, there was a trace of copper, showing that the pyrites employed was not quite free from copper; and in a specimen from the Clyde Iron-Works there was a trace of sulphur. The following table exhibits the composition of six different specimens of cast iron, No. 1, analyzed in my laboratory, either by myself or by Mr. John Tennent.

	Muirkirk.	Muirkirk.	Muirkirk.	Pyrites.	Carron.	Clyde.	Mean.
Iron,	90·98	90·29	91·38	89·442	94·010	90·824	91·154
Copper,	...	...	...	0·288	...	...	
Manganese,	...	7.14	2·00	...	0·626	2·458	2·037

Aluminum,	0·48	0·016	...	3·776	1·032	4·602	1·651
Calcium,	...	0·018	0·20	...	...	...	
Magnesium,	...	...	...	...	...	0·340	

"The constant constituents of cold-blast cast-iron, No. 1, are iron, manganese, carbon, silicon, and aluminum. The occasional constituents are copper, sulphur, calcium, and magnesium. These occur so rarely, and in such minute quantity, that we may overlook them altogether.

"The constant constituents occur in the following mean atomic proportions:

22	atoms iron,	= 77·00
½	atom manganese,	= 1·75
4·36	atoms carbon,	= 3·27
1	atom silicon,	= 1·00
1⅛	aluminum,	= 1·40—84·42

"2. I examined only one specimen of cast-iron, No. 2. It was an old specimen, said to have come from Sweden, but I have no evidence of the correctness of this statement. Its specific gravity was 7·1633 higher than any specimens of cold-blast iron, No. 1. Its constituents were,

Iron,	93·594
Manganese,	0·708
Carbon,	3·080
Silicon,	1·262
Aluminum,	0·732
Sulphur,	0·038—99·414

"The presence of sulphur in this specimen leads to the suspicion that it is not a Swedish specimen; for as the Swedish ore is magnetic iron, and the fuel charcoal, the presence of sulphur in the iron is very unlikely.[1]

"In this specimen, the atoms of iron and manganese are to those of carbon, silicon, and aluminum, in the proportion of 4½ to one, instead of 3½ to one, as in cast-iron No. 1.

"The atoms of carbon, silicon, and aluminum, approach the proportions of 7, 2, and 1, so that in cast-iron, No, 2, judging from one specimen, there is a greater proportion of carbon, compared with the silicon and aluminum, than in cast-iron, No. 1.

"Mr. Tennent analyzed a specimen of hot blast-iron, No. 2, from Gartsherry. Its specific gravity was 6·9156, and its constituents,

		Atoms.	
Iron,	90·542	25·86	3·72
Manganese,	2·764	0·78	
Carbon,	3·094	4·05	1·
Silicon,	0·680	0·68	
Aluminum,	2·894	2·31	
Sulphur,	0·023	0·011	
	99·997		

So that it resembles cast-iron, No. 1, in the proportion of its constituents. The carbon is almost the same as in cold-blast iron, No, 2, but the proportion of aluminum is four times as great, while the silicon is little more than half as much. The atomic ratios are, carbon, 4·; silicon, 0·67; aluminum, 2·28.

"3. Five specimens of hot-blast cast iron, No. 1, were analyzed. Two of these were from Carron, and three from the Clyde Iron-Works, where the hot-blast originally began; and where, of course, it has been longest in use. The specific gravity of these specimens was found to be as follows:

1st. From Clyde Works	7·0028
2d. From Carron,	7·0721
3d. From Carron,	7·0721
4th. From Clyde Works,	7·1022
Mean,	7·0623

"It appears from this, that the hot-blast increases the specific gravity of cast-iron by about $\frac{1}{22}$nd part. It approaches nearer the specific gravity of cast iron No. 2, smelted by cold air, than to that of No. 1.

"The following table exhibits the constituents of these four specimens.

	Clyde.	Carron.	Carron.	Clyde.	Clyde.
Iron,	97·096	95·422	96·09	94·966	94·345
Manganese,	0·332	0·336	0·41	0·160	3·120
Carbon,	2·460	2·400	2·48	1·560	1·416
Silicon,	0·280	1·820	1·49	1·322	0·520
Aluminum,	0·385	0·488	0·26	1·374	0·599
Magnesium,	...	...	...	0·792	...
	100·55	100·466	100·73	100·174	100·

The mean of these analyses gives us,

		Atoms.	
Iron,	95·584 or	27·31	6·5
Manganese,	0·871 or	0·249	
Carbon,	2·099 or	2·79	1·
Silicon,	1·086 or	1·086	
Aluminum,	0·422 or	0·337	
	101·285		

Or, in the proportion of 6½ atoms of iron and manganese to 1 atom of carbon, silicon, and aluminum. In the cold-blast cast-iron we have,

	Iron.	Carbon. &c.
In No. 1,	3½ atoms	1 atom.
In No. 2,	4½	1 —
In hot-blast,	6½	1 —

"Thus it appears, that when iron is smelted by the hot-blast its specific gravity is increased, and it contains a greater proportion of iron, and a smaller proportion of carbon, silicon, and aluminum, than when smelted by the cold-blast.

---

[1] I have been told by Mr. Mushet that the Swedes add sulphur to their iron No. 2.

At the request of the British Association, Mr. Eaton Hodgkinson examined the mechanical properties of hot and cold-blast iron. The following are his general results.

Carron Iron, No. 2.

	Cold-Blast.	Hot-Blast.	Ratio representing Cold Blast by 1000.
Tensile strength in lbs. per square inch..............	16683 (2)	13505 (3)	1000 : 809
Compressive ditto in lbs. per inch from castings torn asunder....	106375 (3)	108540 (2)	1000 : 1020
Do. from prisms of various forms	100631 (4)	100738 (2)	1000 : 1001 Mean 997
Do. from cylinders	125403 (13)	121685 (13)	1000 : 970
Transverse strength from all the experiments	.... (11)	.... (13)	1000 : 991
Power to resist impact	.... (9)	.... (9)	1000 : 1005
Transverse strength of bars one inch square in ibs............	476 (3)	463 (3)	1000 : 973
Ultimate deflection of do. in in.	1·313 (3)	1·337 (3)	1000 : 1018
Modulus of elasticity in lbs. per square inch.....	17270500 (2)	16085000 (2)	1000 : 931
Specific gravity......	7066	7046	1000 : 997

Devon Iron, No. 3.

	Cold-Blast.	Hot-Blast.	Ratio representing Cold Blast by 1000.
Tensile strength.....	....	21907 (1)	
Compressive ditto	....	145435 (4)	
Transverse ditto from the experiments generally	.... (5)	.... (5)	1000 : 1417
Power to resist impact	.... (4)	.... (4)	1000 : 2786
Transverse strength of bars one inch square	448 (2)	537 (2)	1000 : 1199
Ultimate deflection ditto........	·79 (2)	1·09 (2)	1000 : 1380
Modulus of elasticity ditto.......	22907700 (2)	22473650 (2)	1000 : 981
Specific gravity......	7295 (4)	7229 (2)	1000 : 991

Buffery Iron, No. 1.

	Cold-Blast.	Hot-Blast.	Ratio representing Cold Blast by 1000.
Tensile strength......	17466 (1)	13434 (1)	1000 : 769
Compressive ditto...	93366 (4)	86397 (4)	1000 : 925
Transverse ditto....	.... (5)	.... (5)	1000 : 931
Power to resist impact	.... (2)	.... (2)	1000 : 963
Transverse strength of bars one inch square	463 (3)	436 (3)	1000 : 942
Ultimate deflection do..........	1·55 (3)	1·64 (3)	1000 : 1058
Modulus of elasticity ditto......	15381200 (2)	13730500 (2)	1000 : 893
Specific gravity......	7079	6998	1000 : 989

Coed-Talon Iron, No. 2.

	Cold-Blast.	Hot-Blast.	Ratio representing Cold Blast by 1000.
Tensile strength.....	18855 (2)	16676 (2)	1000 : 884
Compressive ditto...	81770 (4)	82739 (4)	1000 : 1012
Specific gravity.....	6955 (4)	6968 (3)	1000 : 1002

Carron Iron, No. 3.

	Cold-Blast.	Hot-Blast.	Ratio representing Cold Blast by 1000.
Tensile strength	14200 (2)	17755 (2)	1000 : 1250
Compressive ditto...	115442 (4)	133440 (3)	1000 : 1156
Specific gravity......	7135 (1)	7056 (1)	1000 : 989

"Of the three columns of numbers in the table above, the first is the strength or other quality in the cold-blast iron; the second is that in the hot-blast; and the third is the ratio of these quantities.

"The results in this table contain nearly the whole information relative to the question of hot and cold-blast-iron that the preceding research affords; and before adverting to them, it may be mentioned, that it is usual for the makers of cast-iron to divide it, when taken from the furnace, into three classes, called Nos. 1, 2, 3, differing from each other in the appearance and qualities of the material. No. 1 contains the softest and richest irons, those which have the largest crystals; No. 3, the hardest and densest irons, those with the least crystals; and No. 2, irons intermediate between the former two descriptions. Beginning with the No. 1 iron, of which we have a specimen from the Buffery Iron-Works, a few miles from Birmingham, we find the cold-blast iron somewhat surpassing the hot-blast in all the following particulars; direct tensile strength, compressive strength, transverse strength, power to resist impact, modulus of elasticity or stiffness, specific gravity; whilst the only numerical advantage possessed by the hot-blast iron is, that it bends a little more than the cold-blast before it breaks.

"In the irons of the quality No. 2, the case seems in some degree different; in these the advantages of the rival kinds seem to be more nearly balanced. They are still, however, rather in favour of the cold blast.

"Referring to the No. 2 iron, from the Carron Works in Scotland, we find the tensile, compressive, and transverse strengths, together with the modulus of elasticity and specific gravity, all higher in the cold-blast iron than the hot-blast, whilst the ultimate deflection and power of sustaining impact are greater in the hot-blast. The cold-blast iron is the better, but the difference is very small.

"In the iron No. 2, from the Coed-Talon Works in North Wales, the tensile strength is greater in the cold-blast than in the hot; but the resistance to compression is higher in the latter than the former, and that is the case with the specific gravity.

"So far as my experiments have proceeded, the irons of No. 1 have been deteriorated by the hot-blast; those of No. 2 appear also to have been slightly injured by it; while the irons of No. 3 seem to have benefited by its mollifying powers. The Carron iron No. 3, hot-blast, resists both tension and compression with considerably more energy than that made with the cold-blast; and the No. 3 hot-blast iron from the Devon Works, in Scotland, is one of the strongest cast-irons I have seen, whilst that made with the cold-blast is comparatively weak, though its specific gravity is very high, and higher than in the hot. The extreme hardness of the cold-blast Devon iron above prevented many experiments that would otherwise have been made upon it, no tools being hard enough to form the specimens. The difference of strength in the Devon irons is peculiarly striking.

"From the evidence here brought forward, it is rendered exceedingly probable that the introduction of a heated blast into the manufacture of cast-iron has injured the softer irons, whilst it has frequently mollified and improved those of a harder nature; and considering the small deterioration that the irons of the quality No. 2 have sustained, and the apparent benefit to those of No. 3, together with the great saving effected by the heated blast, there seems good reason for the process becoming as general as it has done." (C. A.)

SMITH, Sir Thomas, was born at Walden in Essex, in the year 1512. At fourteen he was sent to Queen's College, Cambridge, where he distinguished himself so much, that he was made Henry the Eighth's scholar, together with John Cheke. He was chosen a fellow of his college in 1531, and appointed two years afterwards to read the public Greek lecture. The common mode of reading Greek at that time was very faulty, the same sound being given to the letters and diphthongs, ι, η, υ, ει, οι, υι. Smith and Cheke had been for some time sensible that this pronunciation was wrong; and after a good deal of consultation and research, they agreed to introduce that mode of reading which prevails at present. Smith was lecturing on Aristotle *De*

Republica, in Greek. At first he dropped a word or two at intervals in the new pronunciation, and sometimes he would stop as if he had committed a mistake, and correct himself. No notice was taken of this for two or three days; but as he repeated it more frequently, his audience began to wonder at the unusual sounds, and at last some of his friends mentioned to him what they had remarked. He owned that something was in agitation, but that it was not yet sufficiently digested to be made public. They entreated him earnestly to discover his project, He did so, and in a short time great numbers resorted to him for information. The new pronunciation was adopted with enthusiasm, and soon became universal at Cambridge. It was afterwards opposed by Bishop Gardiner the chancellor; but its superiority to the old mode was so visible, that in a few years it spread over all England.

In 1539 he travelled into foreign countries, and studied for some time in the universities of France and Italy. At Padua he took the degree of LL.D. On his return, he was admitted *ad eundem* at Cambridge, and was appointed regius professor of the civil law. He was useful in promoting the reformation of religion as well as of learning. Having gone into the family of the duke of Somerset the protector, during the minority of Edward the Sixth, he was employed by that nobleman in public affairs; and in 1548 he was made secretary of state, and received the honour of knighthood. While Somerset continued in office, he was sent as ambassador, first to Brussels, and afterwards to France. Upon the accession of Mary, he lost all his places, but was fortunate enough to preserve the friendship of Gardiner and Bonner. He was exempted from persecution, and was allowed, probably by their influence, a pension of L.100. During Elizabeth's reign he was employed in public affairs, and was thrice sent to France in the capacity of an ambassador. He died in the year 1577.

Sir Thomas Smith was a man of excellent talents, united with solid and variegated learning. He obtained a respectable place among the scholars of the age, by the publication of his epistle to the bishop of Winchester, "De recta et emendata Linguae Graecae Pronuntiatione." Lutetiae, 1568, 4to. The same volume includes his dialogue, "De recta et emendata Linguae Anglicanae Scriptione." But the work by which he is best known in modern times, is entitled "*De Republiea Anglorum:* the Maner of Gouernment or Policie of the Realme of England." Lond. 1583, 4to. Of this treatise, which was translated into Latin, there are many editions.

SMITH, EDMUND, an English poet, the only son of Mr. Neale, an eminent merchant, by a daughter of Baron Lechmere, was born in 1668. By his father's death, he was left young to the care of Mr. Smith, who had married his father's sister, and who treated him with so much tenderness, that at the death of his generous guardian, he assumed his name. His writings are not many, and these are scattered in miscellanies and collections. His celebrated tragedy of Phædra and Hippolytus was acted in 1707; and being introduced at a time when the Italian opera so much engrossed the attention of the polite world, gave Mr. Addison, who wrote the prologue, an opportunity to rally the vitiated taste of the public. Notwithstanding the esteem in which it has always been held, it is perhaps rather to be considered as a fine poem than as a good play. This tragedy, with a poem to the memory of Mr. John Philips, three or four odes, with a Latin oration spoken at Oxford, *In laudem Thomæ Bodleii*, were published as his works by his friend Mr. Oldisworth. Mr. Smith died in 1710.

SMITH, ADAM, was born at Kirkcaldy, on the 5th of June 1723. His father, who held the situation of comptroller of customs in that town, died a few months before his birth; so that the charge of his early education devolved wholly on his mother, the daughter of Mr. Douglas of Strathenry, in the county of Fife. His constitution during infancy is said to have been extremely infirm and delicate, and required all the anxious attention of his mother, who treated him with the greatest indulgence. This did not, however, produce any unfavourable effect on his temper or dispositions; and he repaid the fond solicitude of his parent by every attention that filial gratitude and affection could dictate, during the long period of sixty years. When only three years of age, he was stolen from Strathenry, to which place he had been carried by his mother, by a party of gipsys. Fortunately, however, for the best interests of mankind, he was speedily recovered by the exertions of his uncle.

He received the first rudiments of his education in the grammar school of Kirkcaldy. The weakness of his constitution prevented him from indulging in the amusements common to boys of his age. But Mr. Stewart states, that he was even then distinguished by his passion for books, and by the extraordinary powers of his memory; that he was much beloved by his school-fellows, many of whom subsequently attained to great eminence, for his friendly and generous disposition; and that even then he was remarkable for those habits which remained with him through life, of speaking to himself when alone, and of mental absence in company. He continued at Kirkcaldy until 1737, when he was sent to the University of Glasgow, where he remained for three years. He then entered Balliol College, Oxford, as an exhibitor on Snell's foundation; and he continued for seven years to prosecute his studies at that celebrated seminary.

Mr. Stewart mentions, on the authority of Dr. Maclaine of the Hague, that mathematics and natural philosophy formed young Smith's favourite pursuits while at Glasgow. But subsequently to his removal to Oxford he seems to have entirely abandoned them, and to have principally devoted the time not consumed in the routine duty of the University to the study of polite literature, and of those moral and political sciences of which he was destined afterwards to become so great a master. Smith does not seem to have felt any very peculiar respect for his English *alma mater*. The severe remarks in the *Wealth of Nations* on the system of education followed in Oxford and Cambridge, had evidently been suggested by his own observation.

While he resided at Oxford, something had occurred to excite the suspicions of his superiors with respect to the nature of his private pursuits; and the heads of his college, having entered his apartment without his being aware, unluckily found him engaged reading Hume's *Treatise of Human Nature*. The objectionable work was, of course, seized; the young philosopher being at the same time severely reprimanded.

Subsequently to his return from Oxford in 1747, he continued to reside for nearly two years at Kirkcaldy with his mother. He had been sent to Oxford that he might be qualified for entering the church of England. The ecclesiastical profession was not, however, agreeable to his taste; and in opposition to the advice of his friends, he returned to Scotland, resolved to devote himself exclusively to literary pursuits. In the latter part of the year 1748, he fixed his residence in Edinburgh, where, in consequence of the encouragement and persuasion of Lord Kames, and some of his other friends, he was prevailed upon to deliver, during that and the two following years, a course of lectures on rhetoric and polite literature. The lectures were attended by a respectable auditory, composed chiefly of students of law and theology; and he had the honour to reckon among his pupils Mr. Wedderburne, afterwards Lord Loughborough, Mr. William Johnstone, afterwards Sir William Pulteney, and Dr. Blair; with all of whom he subsequently continued on the most intimate terms. It was also at this period that he laid the foundation of that friendship with David Hume, which lasted, without the slightest interruption, till the death of the latter.

No part of these lectures was ever published; but it would appear from the statement of Dr. Blair, who commenced his course of Lectures on rhetoric in 1758, ten years after Dr. Smith's first course, that they had been reduced into a systematic form. In a note to his eighteenth lecture, Dr. Blair mentions that he had borrowed several of the ideas respecting the general characters of style, particularly the plain and simple, and the characters of those English authors who are classed under them, from a manuscript treatise of Dr. Smith on Rhetoric, of which the author had shewn him a part.

In consequence of his increasing celebrity, Dr. Smith was elected, in 1751, professor of logic in the University of Glasgow; and the year following he was elevated to the chair of moral philosophy in the same University, vacant by the death of Mr. Craigie, the immediate successor of the celebrated Dr. Hutcheson, under whom Dr. Smith had formerly studied. He continued to hold this situation for thirteen years; and, as the studies and inquiries in which his academical duties daily engaged him, were the most agreeable to his taste, it is not surprising that he should have considered the period of his residence at Glasgow as the happiest portion of his life. At the same time, it seems reasonable to conclude that his professional pursuits must have had a great effect in maturing his speculations in morals and politics, and, consequently, in determining him to undertake those great works which have immortalized his name, and largely benefited the whole human race.

Mr. Millar, the distinguished author of the *Historical View of the English Government*, and professor of law in the University of Glasgow, had the advantage of hearing Dr. Smith's course of lectures on moral philosophy; of which he has given the following account: "There was no situation in which the abilities of Dr. Smith appeared to greater advantage than as a professor. In delivering his lectures, he trusted almost entirely to extemporary elocution. His manner, though not graceful, was plain and unaffected; and, as he seemed to be always interested in the subject, he never failed to interest his hearers. Each discourse consisted commonly of several distinct propositions, which he successively endeavoured to prove and illustrate. These propositions, when announced in general terms, had, from their extent, not unfrequently something of the air of a paradox. In his attempts to explain them, he often appeared, at first, not to be always interested in the subject, and spoke with some hesitation. As he advanced, however, the matter seemed to crowd upon him, his manner became warm and animated, and his expression easy and fluent. In points susceptible of controversy, you could easily discern, that he secretly conceived an opposition to his opinions, and that he was led upon this account to support them with greater energy and vehemence. By the fulness and variety of his illustrations, the subject gradually swelled in his hands, and acquired a dimension which, without a tedious repetition of the same views, was calculated to seize the attention of his audience, and to afford them pleasure, as well as instruction, in following the same object through all the diversity of shades and aspects in which it was presented, and afterwards in tracing it backwards to that original proposition or general truth from which this beautiful train of speculation had proceeded.

"His reputation as a professor was accordingly raised very high, and a multitude of students from a great distance resorted to the University, merely upon his account. Those branches of science which he taught became fashionable at this place, and his opinions were the chief topic of discussion in clubs and literary societies. Even the small peculiarities in his pronunciation or manner of speaking became frequently the objects of imitation."

It is understood that Dr. Smith made his debût as an author by contributing, anonymously, two articles to a publication entitled the *Edinburgh Review*, commenced in 1755, of which only two numbers were published. The first of these articles is a review of Dr. Johnson's Dictionary, and displays considerable acuteness; the second is in the form of a letter to the editor, and contains some general observations on the literature of the different European countries. It is chiefly remarkable as evincing the attention paid by the author to continental literature, at a period when it was comparatively neglected in this country.

In 1759 Smith published his *Theory of Moral Sentiments.* He had been engaged for a very considerable period in the composition of this work, which is throughout elaborated with the greatest care. The fundamental principle maintained by the author is, that *sympathy* forms the real foundation of morals; that we do not immediately approve or disapprove of any given action, when we have become acquainted with the intention of the agent and the consequences of what he has done, but that we previously enter, by means of that sympathetic affection which is natural to us, into the feelings of the agent and those to whom the action relates; that, having considered all the motives, and passions by which the agent was actuated, we pronounce, with respect to the *propriety* or *impropriety* of the action, according as we sympathize or not with him; while we pronounce, with respect to the *merit* or *demerit* of the action, according as we sympathize with the gratitude or resentment of those who were its objects; and that we necessarily judge of our own conduct by comparing it with such maxims and rules as we have deduced from observations previously made on the conduct of others.

Several, and, as it is now generally admitted, some unanswerable, objections have been urged against this most ingenious theory. But, whatever difference of opinion may exist with respect to the truth of the principle it involves, the *Theory of Moral Sentiments* has been universally allowed to abound in the most admirable disquisitions, in a faithful and skilful delineation of character, and in the soundest and most elevated maxims for the practical regulation of human life. The style various, but always eloquent, is worthy of the subject; and while it serves, by the beauty and richness of its colouring, to relieve the dryness of some of the more abstract discussions, it gives additional force to the powerful recommendations of generous, upright, and disinterested conduct to be found in every part of the work.

Dr. Brown, who has criticised this theory with his usual acuteness, and has shewn that though sympathy may diffuse moral sentiments, it can never originate them, bears, notwithstanding, the strongest testimony to the transcendent merits of Dr. Smith's work. "The *Theory of Moral Sentiments*," he observes, "is, without all question, one of the most interesting works, perhaps I should have said the most interesting work, in moral science. It is valuable, however, as I before remarked, not for the leading doctrine, of which we have seen the fallacy, but for the minor theories which are adduced in illustration of it; for the refined analysis which it exhibits in many of its details; and for an eloquence which, adapting itself to all the temporary varieties of its subject, familiar, with a sort of majestic grace, and simple even in its magnificence, can play amid the little decencies and proprieties of common life, or rise to all the dignity of that sublime and celestial virtue, which it seems to bring from heaven indeed, but to bring down gently and humbly, to the bosom of man."[1]

---

[1] Brown's Lectures, vol. iv. p. 132. edit. 1824.

Having published the substance of so important a part of his lectures, Smith was enabled to make considerable retrenchments from the ethical parts of his course, and to give a proportionally greater extension to the disquisitions on Jurisprudence and Political Economy. He had long been in the habit of embodying in his lectures the results of his studies and investigations with respect to both these departments of political science, and particularly the latter; and it appears from a statement which he drew up in 1755, in order to vindicate his claims to certain political and literary opinions, that he had been in the habit of teaching, from the time he obtained a chair in the University of Glasgow, and even when at Edinburgh, the same enlarged and liberal doctrines with respect to the freedom of industry, and the impolicy and injurious influence of artificial restraints and regulations, which he afterwards so fully established in the *Wealth of Nations*. His residence in a large commercial city, like Glasgow, gave him considerable advantage in the prosecution of his favourite studies, by affording means of easily obtaining that correct practical information, on many points, which cannot be learned from books, and by enabling him to compare his theoretical doctrines with the experimental conclusions of his mercantile friends. Notwithstanding the disinclination so common among men of business, to listen to speculative opinions, and the opposition of his leading principles to the old maxims of trade, he was able, before he quitted his situation in the University, to rank some very eminent merchants among his proselytes.

The publication of the *Theory of Moral Sentiments* brought a great accession of reputation to the author; and placed him, in the estimation of all who were qualified to form an opinion on such a subject, in the first rank of moralists, and of able and eloquent writers. In 1762 the Senate of the University of Glasgow unanimously conferred on him the degree of Doctor of Laws; in testimony, as it is expressed in the minutes of the meeting, of their respect for his universally acknowledged talents, and of the advantage that had resulted to the University from the ability with which he had for many years expounded the principles of jurisprudence. But the most important effect of his increasing celebrity, in so far at least as respected himself, was his receiving in 1763 an invitation from Mr. Charles Townsend, who had married the Duchess of Buccleugh, to attend her Grace's son, the young Duke, on his travels; and the advantageous terms that were offered, combined with the strong desire which he entertained of visiting the Continent, induced him to accept the offer, and to resign his chair at Glasgow. "With the connexion which he was led to form in consequence of this change in his situation," says Mr. Stewart, "he had reason to be satisfied in an uncommon degree, and he always spoke of it with pleasure and gratitude. To the public it was not, perhaps, a change equally fortunate; as it interrupted that studious leisure for which nature seems to have destined him, and in which alone he could have hoped to accomplish those literary projects which had flattered the ambition of his youthful genius."

Dr. Smith set out for France in company with his noble pupil in March 1764. They remained only a very few days at Paris on their first visit to that capital, but proceeded to Toulouse, where they resided for about eighteen months. The society of Toulouse, a considerable city, and at that time the seat of a parliament, must have been a good deal superior to that of most country towns; and Dr. Smith would, no doubt, avail himself of it, and of the leisure he then enjoyed, to perfect and extend his knowledge of the literature, internal policy, and state of France. He has told us that he was not disposed to place much confidence in the facts and reasonings of political arithmeticians; and it is evident from his rarely stating facts on the authority of others, and from the references he occasionally makes to circumstances connected with Toulouse, Geneva, and other places which he visited, that he was chiefly indebted to his own observation and inquiries for the accurate and extensive information he is universally acknowledged to have possessed with respect to the institutions, habits, and condition of the French people.

After leaving Toulouse, Dr. Smith and his pupil proceeded to Geneva, where they resided two months. They returned to Paris at Christmas, 1765, and remained in that city for nearly twelve months. During the whole of this period, Dr. Smith lived on the most friendly footing with the best society in Paris. Turgot, afterwards comptroller general of Finance, D'Alembert, Helvetius, Marmontel, the Abbé Morellet,[1] the Duc de la Rochefoucault, and Madame Riccoboni, were of the number of his acquaintances; and some of them he continued ever after to reckon among his friends. He was also on familiar terms with M. Quesnay, founder of the sect of the Economists; and there is every reason to think that he derived considerable advantage from his intercourse with that able and excellent person, than whom none was better qualified to strike out original and ingenious views. So sensible, indeed, was Dr. Smith of his great and various merits as a man and a philosopher, that he intended, had he not been prevented by Quesnay's death, to have left a lasting testimony of the estimation in which he held him, by dedicating to him the *Wealth of Nations*.

In October 1766, the Duke of Buccleugh and Dr. Smith returned to London. The latter soon after removed to his old residence at Kirkcaldy; where he continued to reside, with very little interruption, for about ten years, habitually occupied in study, and in the elaboration of his great work. The *Inquiry into the Nature and Causes of the Wealth of Nations* appeared in 1776; an æra that will be for ever memorable in the history of political philosophy. Of this invaluable work, it is sufficient to observe, that, notwithstanding the defects that have been discovered in some of its principles, and the objections that have been made, and, perhaps, with justice, to its arrangement, it will ever remain one of the noblest monuments of profound sagacity, great and varied learning, sound judgment, and persevering research, directed to the best, because the most useful, purposes. There can be no question with respect to the claim of Dr. Smith to be considered as the real founder of the modern system of Political Economy. Though he has not left a perfect work, he has left one which contains a greater number of useful truths than have ever been given to the world by any other individual; and he has pointed out and smoothed the route, by following which subsequent philosophers have been able to perfect much that he left incomplete, to rectify the mistakes into which he fell, and to make many new and important discoveries. Whether indeed we refer to the soundness of its leading doctrines, the liberality and universal applicability of its practical conclusions, or the powerful and beneficial influence which it has had on the progress of economical science, and on the policy and conduct of nations, the *Wealth of Nations* must be placed in

---

[1] The paragraph which follows is extracted from the Mémoires of the Abbé Morellet published in 1821. "J'avais connu Smith dans un voyage qu'il avait fait en France, vers 1762; il parlait fort mal notre langue; mais sa *Théorie des Sentimens Moraux*, publiée en 1759, m'avait donné und grande idée de sa sagacité et de sa profondeur. Et véritablement je le regarde encore aujourd'hui comme une des hommes qui a fait les observations et les analyses les plus complètes dans toutes les questions qu'il a traitées. M. Turgot, qui animait ainsi que moi la métaphysique, estimait beaucoup son talent. Nous le vîmes plusieurs fois; il fut présenté chez Helvétius: nous parlâmes théorie commerciale, banque, crédit public, et de plusieurs points du grand ouvrage qu'il méditait. Il me fit présent d'un fort joli portefeuille anglais de poche, qui était à son usage, et dont je me suis servi vingt ans." Tom. i. p. 237.

the foremost rank of those works that have helped to liberalize, enlighten, and enrich mankind.

Dr. Smith survived the publication of the *Wealth of Nations* fifteen years. He had the satisfaction to see it translated into all the languages of Europe; to hear his opinions quoted in the House of Commons; to be consulted by the minister; and to observe that the principles which he had expounded were beginning to produce a material change in the public opinion, and in the councils of this and other countries; and he must have enjoyed the full conviction that the progress of events would ensure their ultimate triumph, by showing that they were productive of signal advantage, not only to the general mass of mankind, but to the inhabitants of every country which should have good sense enough to adopt them.

Mr. Hume died very soon after the publication of the *Wealth of Nations*. Dr. Smith, with whom he had long lived on the most intimate terms, was most assiduous in his attentions to his illustrious friend during his illness; and he gave a brief account of the circumstances connected with his death, together with a sketch of his character, in a letter addressed to Mr. Strahan of London, which was soon after published as a supplement to Mr. Hume's autobiography. The unqualified eulogium pronounced in this letter on Mr. Hume's character excited the indignation of those who took offence at his religious opinions. Dr. Horne, bishop of Norwich, in an anonymous letter, attacked Dr. Smith on this ground; and very naturally ascribed to him the same sceptical opinions that had been entertained by his deceased friend. But he took no notice of this attack; and wisely declined entering upon a controversy that could have led to no useful result.

Dr. Smith resided principally in London during the two years immediately subsequent to the publication of the *Wealth of Nations;* caressed by the most distinguished persons in the metropolis, who were justly proud of his acquaintance, and who, though they could not always subscribe to the justice of his remarks, were equally delighted with the goodness of his heart, the simplicity of his manners, the vigour of his understanding, and the variety of his attainments. In 1788 he was appointed, through the unsolicited application of his old pupil and friend, the Duke of Buccleugh, a commissioner of customs for Scotland. In consequence of this appointment he removed to Edinburgh, where he continued afterwards to reside, possessed of an income more than equal to his wants, and in the enjoyment of the society of his earliest and most esteemed friends. His mother, then in extreme old age, and his cousin, Miss Douglas, accompanied him to Edinburgh, the latter superintending the domestic arrangements and economy of his family. But though his appointment to the customs reflects high credit on the nobleman by whose intervention it was procured, it may be doubted whether it was worthy of the country or of Dr. Smith. The philosopher who had produced a work in which the true sources of national wealth and prosperity were, for the first time, fully explored and laid open, deserved a different and a higher reward.

In 1787 Dr. Smith was elected Lord Rector of the University of Glasgow; on which occasion he addressed a letter to that learned body, which strikingly evinces the high sense he felt of this honour, and his affectionate regard for those from which it emanated. "No preferment," says he, "could have given me so much real satisfaction. No man can owe greater obligations to a society than I do to the University of Glasgow. They educated me; they sent me to Oxford. Soon after my return to Scotland, they elected me one of their own members; and afterwards preferred me to another office, to which the abilities and virtues of the never to be forgotten Dr. Hutcheson had given a superior degree of illustration. The period of thirteen years, which I spent as a member of that society, I remember as by far the most useful, and therefore as by far the happiest and most honourable, period of my life; and now, after three and twenty years' absence, to be remembered in so very agreeable a manner by my old friends and protectors, gives me a heartfelt joy which I cannot easily express to you."

His constitution, which had at no time been robust, began early to give way; and his decline was accelerated by the grief and vexation he felt on account of the death of his mother, to whom he had been most tenderly attached, in 1784, and of Miss Douglas, in 1788. He survived the latter only about two years, having died in July 1790. His last illness, which was occasioned by a chronic obstruction of the bowels, was both tedious and painful: but he bore it with the greatest fortitude and resignation: his cheerfulness never forsook him; and he had all the consolation that could be derived from the affectionate sympathy and attention of his friends.

His conduct in private life did not belie the generous principles inculcated in his works. He was in the habit of allotting a considerable part of his income to offices of secret charity. Mr. Stewart mentions that he had been made acquainted with some very affecting instances of his beneficence. "They were all," he observes, "on a scale much beyond what might have been expected from his fortune; and were accompanied with circumstances equally honourable to the delicacy of his feelings and the liberality of his heart."

Dr. Smith collected an exceedingly valuable and well-selected, though not a very extensive, library. He was very particular, not only with respect to the books themselves, but also with respect to the condition of the copies admitted into his collection. "The first time," says Mr. Smellie, "I happened to be in his library, observing me looking at the books with some degree of curiosity and perhaps surprise, for most of the volumes were elegantly and some of them superbly bound, 'You must have remarked,' said he, 'that *I am a beau in nothing but my books.*'"[1] His library is still in the possession of Lord Reston's widow.

Notwithstanding the apparent flow and artlessness of his style, and his great experience in composition, Dr. Smith stated, not long before his death, that he continued to compose as slowly, and with as great difficulty, as at first. He did not write with his own hand, but generally walked up and down his apartment, dictating to an amanuensis.[2]

Dr. Smith had been long resolved that none of his manuscripts, except those which he himself judged fit for publication, should ever see the light; and a few days before his death he carried this resolution into effect, by having all his papers committed to the flames, with the exception of the fragments of some essays, intended to illustrate the principles that lead and direct philosophical inquiries, which he left to the discretion of his friends to publish or not as they thought proper. The contents of the manuscripts that were destroyed are not exactly known; but they certainly contained the course of lectures on rhetoric delivered at Edinburgh in 1748, and the lectures on jurisprudence and natural religion, which formed a most important part of the course of moral philosophy delivered at Glasgow. The loss of the latter must ever be a subject of deep regret. We are ignorant of the motives which induced Dr. Smith to destroy them; but Mr. Stewart supposes that it was not so much on account of any apprehended injury to his literary reputation from the publication of such unfinished works, as from an anxiety lest the progress of truth should be retarded by the statement of doctrines of which the principles were not fully developed.

---

[1] Smellie's Lives, p. 296.

[2] Mr. Stewart states that all Hume's works were written with his own hand; and that the last volumes of his history were printed from the original copy, with only a few marginal corrections.

The following observations on the private character and habits of Dr. Smith proceed from the pen of Mr. Stewart, who knew him well, and who was the last survivor of that galaxy of illustrious men who shed, during the last century, so imperishable a glory over the literature of Scotland. "The more delicate and characteristical features of his mind," Mr. Stewart observes, "it is perhaps impossible to trace. That there were many peculiarities, both in his manners and in his intellectual habits, was manifest to the most superficial observer; but although, to those who knew him, these peculiarities detracted nothing from the respect which his abilities commanded; and although, to his intimate friends, they added an inexpressible charm to his conversation, while they displayed, in the most interesting light, the artless simplicity of his heart; yet it would require a very skilful pencil to present them to the public eye. He was certainly not fitted for the general commerce of the world, or for the business of active life. The comprehensive speculations with which he had been occupied from his youth, and the variety of materials which his own invention continually supplied to his thoughts, rendered him habitually inattentive to familiar objects, and to common occurrences; and he frequently exhibited instances of absence, which had scarcely been surpassed by the fancy of La Bruyere. Even in company he was apt to be engrossed with his studies; and appeared at times, by the motion of his lips, as well as by his looks and gestures, to be in the fervour of composition. I have often, however, been struck, at the distance of years, with his accurate memory of the most trifling particulars; and am inclined to believe, from this and some other circumstances, that he possessed a power, not perhaps uncommon among absent men, of recollecting, in consequence of subsequent efforts of reflection, many occurrences which, at the time when they happened, did not seem to have sensibly attracted his notice.

"To the defect now mentioned, it was probably owing, in part, that he did not fall in easily with the common dialogue of conversation, and that he was somewhat apt to convey his own ideas in the form of a lecture. When he did so, however, it never proceeded from a wish to engross the discourse, or to gratify his vanity. His own inclination disposed him so strongly to enjoy in silence the gaiety of those around him, that his friends were often led to concert little schemes, in order to engage him in the discussions most likely to interest him. Nor do I think I shall be accused of going too far when I say, that he was scarcely ever known to start a new topic himself, or to appear unprepared upon those topics that were introduced by others. Indeed, his conversation was never more amusing than when he gave a loose to his genius upon the very few branches of knowledge of which he only possessed the outlines.

"The opinions he formed of men, upon a slight acquaintance, were frequently erroneous; but the tendency of his nature inclined him much more to blind partiality than to ill-founded prejudice. The enlarged views of human affairs, on which his mind habitually dwelt, left him neither time nor inclination to study, in detail, the uninteresting peculiarities of ordinary characters; and accordingly, though intimately acquainted with the capacities of the intellect, and the workings of the heart, and accustomed, in his theories, to mark, with the most delicate hand, the nicest shades, both of genius and of the passions; yet, in judging of individuals, it sometimes happened that his estimates were, in a surprising degree, wide of the truth.

"In his external form and appearance there was nothing uncommon. When perfectly at ease, and when warmed with conversation, his gestures were animated, and not ungraceful; and, in the society of those he loved, his features were often brightened with a smile of inexpressible benignity. In the company of strangers, his tendency to absence, and perhaps still more his consciousness of this tendency, rendered his manner somewhat embarrassed;—an effect which was probably not a little heightened by those speculative ideas of propriety, which his recluse habits tended at once to perfect in his conception, and to diminish his power of realizing."

The following is a list of the published works of Dr. Smith.

1. Two articles in the *Edinburgh Review* for 1755, being, (1) a Review of Johnson's *English Dictionary*, and (2) *A Letter to the Editors*.

2. *The Theory of Moral Sentiments*. The first edition of this work was published in 8vo, early in 1759. The sixth edition was published a short time before the author's death. It contains several additions, most of which were executed during his last illness.

3. *Considerations concerning the first Formation of Languages, and the different Genius of Original and Compounded Languages*. This essay was originally subjoined to the first edition of the *Moral Sentiments*. It is an ingenious and pretty successful attempt to explain the formation and progress of language, by means of that species of investigation to which Dugald Stewart has given the appropriate name of *Theoretical* or *Conjectural History;* and which consists in endeavouring to trace the progress and vicissitudes of any art or science, partly from such historical facts as have reference to it, and, where facts are wanting, from inferences derived from considering what would be the most natural and probable conduct of mankind under the circumstances supposed.

4. *An Inquiry into the Nature and Causes of the Wealth of Nations*. The first edition was published at London in 1776, in two volumes 4to. The fourth edition, which was the last revised by the author, appeared in three volumes 8vo, in 1786.

5. *Essays on Philosophical Subjects*. Lond. 1795, 4to. These are the fragments which he exempted from the general destruction of his manuscripts, and which were published by his friends, Dr. Black and Dr. Hutton. In an advertisement prefixed to the publication, the editors state that, when the papers which Dr. Smith had left in their hands were examined, "the greater number appeared to be parts of a plan he once had formed for giving a connected history of the liberal sciences and elegant arts." "It is long," they add, "since he found it necessary to abandon that plan as far too extensive; and these parts of it lay beside him neglected until his death. The reader will find in them that happy connection, that full and accurate expression, and that clear illustration, which are conspicuous in the rest of his works; and though it is difficult to add much to the great fame he so justly acquired by his other writings, these will be read with satisfaction and pleasure." The papers in question comprise, I. fragments of a great work *On the Principles which lead and direct Philosophical Inquiries, illustrated* (1) *by the History of Astronomy;* (2) *by the History of the Ancient Physics;* and (3) *by the History of the Ancient Logics and Metaphysics*. II. An essay entitled, *Of the Nature of that Imitation which takes place in what are called the imitative Arts*. III. A short tract, *Of the Affinity between certain English and Italian Verses*. IV. A disquisition, *Of the External Senses*.

Of the historical dissertations, the first only, on the *History of Astronomy*, seems to be nearly complete. They are all written on the plan of the dissertation on the *Formation of Languages*, being partly theoretical and partly founded on fact. In the essay on the *History of Astronomy*, after premising some acute and ingenious speculations with respect to the effects of unexpectedness and surprise, and of wonder and novelty, the author proceeds to give a brief, masterly, outline of the different astronomical systems, from the earliest ages down to that of Newton. The fragments that remain of the other two historical essays are much less complete, and do not possess the interest of the former. The short essay, *Of the Affinity between certain English and Italian Verses*, is curious rather than valuable. It affords a striking illustration of the variety and extent of Dr. Smith's literary pursuits. The disquisition with respect to the *External Senses* is of considerable extent. It embraces some ingenious discussions, and is a valuable contribution to the science of which it treats.

The *Wealth of Nations* has passed through many editions, some of which have been accompanied with notes and illustrations; but the best that has yet appeared, is that which was edited by Mr. M'Culloch, with notes and dissertations, embodying the views of later economists, and adapting the work to the present state of that science of which it has so eminently contributed to advance the progress.

SMITHERY, a smith's shop; also the art of a smith, by which iron is wrought into any shape by means of fire, hammering, and filing.

SMITING-LINE, in a ship, is a small rope fastened to the mizen-yard-arm, below at the deck, and is always furled up with the mizen-sail, even to the upper end of the yard, and thence it comes down to the poop. Its use is to loosen the mizen-sail without striking down the yard, which is easily done, because the mizen-sail is furled up only with rope-yarns; and therefore when this rope is pulled hard, it breaks all the rope-yarns, and so the sail falls down of itself. The sailor's phrase is, *smite the mizen*, that is, haul by this rope that the sail may fall down.

SMOAKY CAPE, on the east coast of New Holland. Long. 153. 42. Lat. 30. 55. S.

SMOKE, a dense elastic vapour arising from burning bodies. As this vapour is extremely disagreeable, and often prejudicial to health, several contrivances have been devised for the purpose of enabling us to enjoy the benefit of a fire without being annoyed by smoke; hence the use of chimneys, which, when properly constructed, carry it off entirely, but when improperly constructed, allow a part of it to escape into the room.

Chimneys operate in carrying off smoke by the rarity of the gaseous fluids which escape from the fire, and which, owing to their being expanded, are lighter than the adjoining air, and are therefore pressed up by it, carrying the smoke along with them. So long, then, as the gaseous products of the fire are lighter than the air, they ascend, while at the same time cold air must rush in from below to supply their place, which air, being heated in its turn, consumed, and mixed with the smoke, must also rise. The more, therefore, that the air in the chimney can be kept warm, so much the better; not only will the draught become greater, but there will also be less chance of any of the smoke being thrown back. The worse the power of the material of which the chimney is constructed for transmitting heat, the longer will the air within it be kept warm, and therefore the chimney will work better; hence the superior efficacy of bricks.

It is evident from what has been said, that there is a certain height to which chimneys may be carried, beyond which any farther lengthening, instead of being beneficial, will prove injurious; because, when the air within the chimney and without become of the same weight, which must be at a particular height in each, then if that chimney be made higher, the air within does not escape, or escapes slowly; air must therefore enter in slowly from below, and consequently the draught must be diminished. There are many circumstances which prevent chimneys from working well, or in other words, which make them return a part of the smoke into the room.

The causes of the smoking of chimneys may be reduced to nine, differing from each other, and therefore requiring different remedies.

1. *Smoky chimneys in a new house are such frequently from mere want of air.* The workmanship of the rooms being all good, and just out of the workman's hands, the joints of the boards of the flooring, and of the panels of wainscotting, are all true and tight; the more so as the walls, perhaps not yet thoroughly dry, preserve a dampness in the air of the room which keeps the wood-work swelled and close. The doors and the sashes too, being worked with truth, shut with exactness, so that the room is as tight as a snuff-box, no passage being left open for air to enter except the key-hole, and even that is sometimes covered by a little dropping shutter. Now if smoke cannot rise but as connected with rarefied air, and a column of such air, suppose it filling the funnel, cannot rise unless other air be admitted to supply its place; and if therefore no current of air enter the opening of the chimney, there is nothing to prevent the smoke from being diffused in the room. If the motion upwards of the air in a chimney that is freely supplied be observed by the rising of the smoke or a feather in it, and it be considered that in the time such feather takes in rising from the fire to the top of the chimney, a column of air equal to the content of the funnel must be discharged, and an equal quantity supplied from the room below, it will appear absolutely impossible that this operation should go on if the tight room is kept shut; for were there any force capable of drawing constantly so much air out of it, it must soon be exhausted like the receiver of an air-pump, and no animal could live in it. Those therefore who stop every crevice in a room to prevent the admission of fresh air, and yet would have their chimney carry up the smoke, require inconsistencies, and expect impossibilities. Yet under this situation it is not uncommon to see the owner of a new house in despair, and ready to sell it for much less than it cost; conceiving it uninhabitable because not a chimney in any one of its rooms will carry off the smoke unless a door or window be left open. Much expense has also been incurred to alter and amend new chimneys which had really no fault. In one house particularly which Dr. Franklin knew that belonged to a nobleman in Westminster, that expense amounted to no less than L.300, after his house had been, as he thought, finished, and all charges paid. And after all, several of the alterations were ineffectual, for want of understanding the true principles.

Remedies. When you find on trial that opening the door or a window enables the chimney to carry up all the smoke, you may be sure that want of air from without is the cause of its smoking. "I say from *without*," adds Dr. Franklin, "to guard you against a common mistake of those who may tell you the room is large, contains abundance of air sufficient to supply any chimney, and therefore it cannot be that the chimney wants air. These reasoners are ignorant that the largeness of a room, if tight, is in this case of small importance, since it cannot part with a chimneyfull of its air without occasioning so much vacuum; which it requires a great force to effect, and could not be borne if effected."

It appearing plainly then, that some of the outward air must be admitted, the question will be, how much is absolutely necessary? for you would avoid admitting more, as being contrary to one of your intentions in having a fire, namely, that of warming your room. To discover this quantity, shut the door gradually while a middling fire is burning, till you find that before it is quite shut the smoke begins to come out into the room; then open it a little till you perceive the smoke comes out no longer. There hold the door, and observe the width of the open crevice between the edge of the door and the rabbet into which it should shut.

Suppose the distance to be half an inch, and the door eight feet high; you thence find that your room requires an entrance for air equal in area to ninety-six half inches, or forty-eight square inches, or a passage of six inches by eight. This, however, is a large supposition, there being few chimneys that, having a moderate opening and a tolerable height of funnel, will not be satisfied with such a crevice of a quarter of an inch. Dr. Franklin found a square of six by six, or thirty-six square inches, to be a pretty good medium that will serve for most chimneys. High funnels with small and low openings may indeed be supplied through a less space; because, for reasons that will hereafter appear, the force of levity, if one may so speak, being greater in such funnels, the cool air enters the room with greater velocity, and consequently more enters in the same time. This, however, has its limits; for experience shews, that no increased velocity so occasioned has made the admission of air through the key-hole equal in quantity to that through an open door, though through the door the current moves slowly, and through the key-hole with great rapidity.

It remains then to be considered how and where this necessary quantity of air from without is to be admitted so as to be least inconvenient; for if at the door, left so much open, the air thence proceeds directly to the chimney, and in its way comes cold to your back and heels as you sit before your fire. If you keep the door shut, and raise a little the sash of your window, you feel a similar inconvenience. Various have been the contrivances to avoid this, such as bringing in fresh air through pipes in the jams of the chimney, which pointing upwards should blow the smoke up the funnel; opening passages in the funnel above, to admit air for the same purpose. But these produce an effect contrary to that intended; for as it is the constant current of air passing from the room through the opening of the chimney into the funnel which prevents the smoke from coming out into the room, if you supply the funnel by other means or in other ways with the air which it requires, and especially if that air be cold, you diminish the force of that current, and the smoke in its efforts to enter the room finds less resistance.

The required air must then indispensably be admitted into the room, to supply what goes off through the opening of the chimney. M. Gauger, a very ingenious and intelligent French writer on the subject, proposes with judgment to admit it above the opening of the chimney; and to prevent inconvenience from its coldness, he directs that it may be so made, that it shall pass in its entrance through winding cavities made behind the iron back and sides of the fire-place, and under the iron hearth-plate; in which cavities it will be warmed, and even heated, so as to contribute much, instead of cooling, to the warming of the room. This invention is excellent in itself, and may be used with advantage in building new houses, because the chimneys may then be so disposed as to admit conveniently the cold air to enter such passages. But in houses built without such views, the chimneys are often so situated as not to afford that convenience without great and expensive alterations. Easy and cheap methods, though not quite so perfect in themselves, are of more general utility; and such are the following.

In all rooms where there is a fire, the body of air warmed and rarefied before the chimney is continually changing place, and making room for other air that is to be warmed in its turn. Part of it enters and goes up the chimney, and the rest rises and takes place near the ceiling. If the room be lofty, that warm air remains above our heads as long as it continues warm, and we are little benefited by it, because it does not descend till it is cooler. Few can imagine the difference of climate between the upper and lower parts of such a room, who have not tried it by the thermometer, or by going up a ladder till their heads are near the ceiling. It is then among this warm air that the requisite quantity of outward air is best admitted, with which being mixed, its coldness is abated, and its inconvenience diminished so as to become scarcely observable. This may be easily done by drawing down about an inch the upper sash of a window; or, if not moveable, by cutting such a crevice through its frame; in both which cases it will be well to place a thin shelf of the length to conceal the opening, and sloping upwards, to direct the entering air horizontally along and under the ceiling. In some houses the air may be admitted by such a crevice made in the wainscot, cornice, or plastering, near the ceiling and over the opening of the chimney. This, if practicable, is to be chosen, because the entering cold air will there meet with the warmest rising air from before the fire, and be soonest tempered by the mixture. The same kind of shelf should also be placed here. Another way, and not a very difficult one, is to take out an upper pane of glass in one of your sashes, set it in a tin frame, giving it two springing angular sides, and then replacing it, with hinges below, on which it may be turned to open more or less above. It will then have the appearance of an internal sky-light. By drawing this pane in, more or less, you may admit what air you find necessary. Its position will naturally throw that air up and along the ceiling. In England some have of late years cut a round hole about five inches diameter in a pane of the sash, and placed against it a circular plate of tin hung on an axis, and cut into vanes; which, being separately bent a little obliquely, are acted upon by the entering air, so as to force the plate continually round like the vanes of a windmill. This admits the outward air, and by the continual whirling of the vanes, does in some degree disperse it. The noise only is a little inconvenient.

2. A second cause of the smoking of chimneys is, *their openings in the room being too large*: that is, too wide, too high, or both. Architects in general have no other ideas of proportion in the opening of a chimney than what relate to symmetry and beauty respecting the dimensions of the room; while its true proportion respecting its function and utility depends on quite other principles; and they might as properly proportion the step in a staircase to the height of the storey, instead of the natural elevation of men's legs in mounting. The proportion then to be regarded, is what relates to the height of the funnel. For as the funnels in the different storeys of a house are necessarily of different heights or lengths, that from the lowest floor being the highest or longest, and those of the other floors shorter and shorter, till we come to those in the garrets, which are of course the shortest; and the force of draft being, as already said, in proportion to the height of funnel filled with rarefied air, and a current of air from the room into the chimney, sufficient to fill the opening, being necessary to oppose and prevent the smoke from coming out into the room; it follows, that the openings of the longest funnels may be larger, and that those of the shorter funnels should be smaller. For if there be a larger opening to a chimney that does not draw strongly, the funnel may happen to be furnished with the air which it demands by a partial current entering on one side of the opening, and leaving the other side free of any opposing current, may permit the smoke to issue there into the room. Much, too, of the force of draft in a funnel depends on the degree of rarefaction in the air it contains, and that depends on the nearness to the fire of its passage in entering the funnel. If it can enter far from the fire on each side, or far above the fire, in a wide or high opening, it receives little heat in passing by the fire, and the contents of the funnel are by those means less different in levity from the surrounding atmosphere, and its force in drawing consequently weaker. Hence, if too large an opening be given to chimneys in upper rooms, those rooms will be smoky. On the other hand, if too small openings be given to chimneys in the lower rooms,

the entering air operating too directly and violently on the fire, and afterwards strengthening the draft as it ascends the funnel, will consume the fuel too rapidly.

Remedy. As different circumstances frequently mix themselves in these matters, it is difficult to give precise dimensions for the openings of all chimneys. Our fathers made them generally much too large. We have lessened them; but still they are often of greater dimensions than they should be, the human eye not being easily reconciled to sudden and great changes. If you suspect that your chimney smokes from the too great dimensions of its opening, contract it by placing moveable boards, so as to lower and narrow it gradually, till you find the smoke no longer issues into the room. The proportion so found will be that which is proper for that chimney, and you may employ the bricklayer or mason to reduce it accordingly. However, as in building new houses something must be sometimes hazarded, Dr. Franklin proposes to make the openings in the lower rooms about thirty inches square, and eighteen deep, and those in the upper only eighteen inches square, and not quite so deep; the intermediate ones diminishing in proportion as the height of the funnel is diminished. In the larger openings, billets of two feet long, or half the common length of cordwood, may be burned conveniently; and for the smaller, such wood may be sawed into thirds. Where coals are the fuel, the grates will be proportioned to the openings. The same depth is nearly necessary to all, the funnels being all made of a size proper to admit a chimney-sweeper. If in large and elegant rooms custom or fancy should require the appearance of a larger chimney, it may be formed of expensive marginal decorations, in marble, or in any thing else. But in time, perhaps, that which is fittest in the nature of things may come to be thought handsomest.

3. Another cause of smoky chimneys is *too short a funnel.* This necessarily happens in some cases, as where a chimney is required in a low building; for, if the funnel be raised high above the roof, in order to strengthen its draft, it is then in danger of being blown down, and crushing the roof in its fall.

Remedies. Contract the opening of the chimney, so as to oblige all the entering air to pass through or very near the fire; whereby it will be more heated and rarefied, the funnel itself be more warmed, and its contents have more of what may be called the force of levity, so as to rise strongly and maintain a good draft at the opening.

Or you may in some cases, to advantage, raise additional storeys over the low building, which will support a high funnel. If the low building be used as a kitchen, and a contraction of the opening therefore inconvenient, a large one being necessary, at least when there are great dinners, for the free management of so many cooking utensils; in such cases the best expedient perhaps would be to build two more funnels joining to the first, and having three moderate openings, one to each funnel, instead of one large one. When there is occasion to use but one, the other two may be kept shut by sliding plates, hereafter to be described; and two or all of them may be used together when wanted. This will indeed be an expense, but not an useless one, since your cooks will work with more comfort, see better than in a smoky kitchen what they are about, your victuals will be cleaner dressed, and not taste of smoke, as is often the case; and to render the effect more certain, a stack of three funnels may be safely built higher above the roof than a single funnel.

The case of too short a funnel is more general than would be imagined, and often found where one would not expect. For it is not uncommon, in ill-contrived buildings, instead of having a funnel for each room or fire-place, to bend and turn the funnel of an upper room, so as to make it enter the side of another funnel that comes from below. By these means the upper room funnel is made short of course, since its length can only be reckoned from the place where it enters the lower room funnel; and that funnel is also shortened by all the distance between the entrance of the second funnel and the top of the stack; for all that part being readily supplied with air through the second funnel, adds no strength to the draft, especially as that air is cold when there is no fire in the second chimney. The only easy remedy here is, to keep the opening of that funnel shut in which there is no fire.

4. Another very common cause of the smoking of chimneys is, *their overpowering one another.* For instance, if there be two chimneys in one large room, and you make fires in both of them, with doors and windows close shut, you will find that the greater and stronger fire shall overpower the weaker, from the funnel of which it will draw down air to supply its own demand; which air descending in the weaker funnel, will drive down its smoke, and force it into the room. If, instead of being in one room, the two chimneys are in two different rooms, communicating by a door, the case is the same whenever that door is open. In a very tight house, a kitchen chimney on the lowest floor, when it had a great fire in it, has been known to overpower any other chimney in the house, and draw air and smoke into its room as often as the door communicating with the staircase was opened.

Remedy. Take care that every room have the means of supplying itself from without with the air which its chimney may require, so that no one of them may be obliged to borrow from another, nor under the necessity of lending. A variety of these means has been already described.

5. Another cause of smoking is, *when the tops of chimneys are commanded by higher buildings, or by a hill,* so that the wind blowing over such eminences falls like water over a dam, sometimes almost perpendicularly on the tops of the chimneys that lie in its way, and beats down the smoke contained in them.

Remedy. That commonly applied in this case is a turncap made of tin or plate iron, covering the chimney above and on three sides, open on one side, turning on a spindle; and which, being guided or governed by a vane, always presents its back to the current. This may be generally effectual, though not certain, as there may be cases in which it will not succeed. Raising your funnels, if practicable, so as their tops may be higher, or at least equal, with the commanding eminence, is more to be depended on. But the turning-cap, being easier and cheaper, should first be tied. "If obliged to build in such a situation, I would choose," says Dr. Franklin, "to place my doors on the side next the hill, and the backs of my chimneys on the farthest side; for then the column of air falling over the eminence, and of course pressing on that below, and forcing it to enter the doors on that side, would tend to balance the pressure down the chimneys, and leave the funnels more free in the exercise of their functions."

6. There is another case which is the reverse of that last mentioned. It is where the commanding eminence is farther from the wind than the chimney commanded.

Remedy. There is but one remedy, which is to raise such a funnel higher than the roof, supporting it if necessary by iron bars. For a turncap in this case has no effect, the dammed-up air pressing down through it in whatever position the wind may have placed its opening.

Dr. Franklin mentions a city in which many houses are rendered smoky by this operation. For their kitchens being built behind, and connected by a passage with the houses, and the tops of the kitchen chimneys lower than the tops of the houses, the whole side of a street when the wind blows against its back, forms such a dam as above described; and the wind so obstructed forces down those kitchen chimneys, especially when they have but weak fires in them, to pass through the passage and house into the street. Kitchen-chimneys so formed and situated have another inconvenience. In summer, if you open your upper-room windows for air, a light breeze blowing over your kitchen chimney towards the house, though not strong enough to force down its smoke as aforesaid, is sufficient to waft it into your windows, and fill the rooms with it, which, besides the disagreeableness, damages your furniture.

7. Chimneys, otherwise drawing well, are sometimes made to smoke by *the improper and inconvenient situation of a door*. When the door and chimney are on the same side of the room, if the door being in the corner is made to open against the wall, which is common, as being there, when open, more out of the way, it follows, that when the door is only opened in part, a current of air rushing in passes along the wall into and across the opening of the chimney, and flirts some of the smoke out into the room. This happens more certainly when the door is shutting, for then the force of the current is augmented, and becomes very inconvenient to those who, warming themselves by the fire, happen to sit in its way.

The *remedies* are obvious and easy. Either put an intervening screen, from the wall round great part of the fire-place; or, which is perhaps preferable, shift the hinges of your door, so that it may open the other way, and when open, throw the air along the other wall.

8. A room that has no fire in its chimney is sometimes filled with *smoke which is received at the top of its funnel and descends into the room*. Funnels without fires have an effect according to their degree of coldness or warmth on the air that happens to be contained in them. The surrounding atmosphere is frequently changing its temperature; but stacks of funnels covered from winds and sun by the house that contains them, retain a more equal temperature. If, after a warm season, the outward air suddenly grows cold, the empty warm funnels begin to draw strongly upwards; that is, they rarefy the air contained in them, which of course rises, cooler air enters below to supply its place, is rarefied in its turn, and rises; and this operation continues till the funnel grows cooler, or the outward air warmer, or both, when the motion ceases. On the other hand, if after a cold season the outward air suddenly grows warm, and of course lighter, the air contained in the cool funnels, being heavier, descends into the room; and the warmer air which enters their tops being cooled in its turn, and made heavier, continues to descend; and this operation goes on till the funnels are warmed by the passing of warm air through them, or the air itself grows cooler. When the temperature of the air and of the funnels is nearly equal, the difference of warmth in the air between day and night is sufficient to produce these currents. The air will begin to ascend the funnels as the cool of the evening comes on, and this current will continue till perhaps nine or ten o'clock next morning, when it begins to hesitate; and as the heat of the day approaches, it sets downwards, and continues so till towards evening, when it again hesitates for some time, and then goes upwards constantly during the night, as before mentioned. Now when smoke issuing from the tops of neighbouring funnels passes over the tops of funnels which are at the time drawing downwards, as they often are in the middle part of the day, such smoke is of necessity drawn into these funnels, and descends with the air into the chamber.

The remedy is to have a sliding plate that will perfectly shut the offending funnel. Dr. Franklin has thus described it. "The opening of the chimney is contracted by brick-work faced with marble slabs to about two feet between the jams, and the breast brought down to within about three feet of the hearth. An iron frame is placed just under the breast, and extending quite to the back of the chimney, so that a plate of the same metal may slide horizontally backwards and forwards in the grooves on each side of the frame. This plate is just so large as to fill the whole space, and shut the chimney entirely when thrust quite in, which is convenient when there is no fire. Draw it out, so as to leave between its further edge and the back a space of about two inches; this space is sufficient for the smoke to pass; and so large a part of the funnel being stopped by the rest of the plate, the passage of warm air out of the room, up the chimney, is obstructed and retarded; and by those means much cold air is prevented from coming in through crevices, to supply its place. This effect is made manifest three ways. 1. When the fire burns briskly in cold weather, the howling or whistling noise made by the wind, as it enters the room through the crevices, when the chimney is open as usual, ceases as soon as the plate is slid in to its proper distance. 2. Opening the door of the room about half an inch, and holding your hand against the opening, near the top of the door, you feel the cold air coming in against your hand, but weakly, if the plate be in. Let another person suddenly draw it out, so as to let the air of the room go up the chimney, with its usual freedom where chimneys are open, and you immediately feel the cold air rushing in strongly. 3. If something be set against the door, just sufficient, when the plate is in, to keep the door nearly shut, by resisting the pressure of the air that would force it open; then, when the plate is drawn out, the door will be forced open by the increased pressure of the outward cold air endeavouring to get in to supply the place of the warm air that now passes out of the room to go up the chimney. In our common open chimneys, half the fuel is wasted, and its effect lost; the air it has warmed being immediately drawn off."

9. Chimneys which generally draw well, do nevertheless sometimes give smoke into the rooms, *it being driven down by strong winds passing over the tops of their funnels*, though not descending from any commanding eminence. This case is most frequent where the funnel is short, and the opening turned from the wind. It is the more grievous, when it happens to be a cold wind that produces the effect, because when you most want your fire you are sometimes obliged to extinguish it. To understand this, it may be considered that the rising light air, to obtain a free issue from the funnel, must push out of its way or oblige the air that is over it to rise. In a time of calm or of little wind this is done visibly; for we see the smoke that is brought up by that air rise in a column above the chimney. But when a violent current of air, that is, a strong wind, passes over the top of a chimney, its particles have received so much force which keeps them in a horizontal direction, and follow each other so rapidly, that the rising light air has not strength sufficient to oblige them to quit that direction and move upwards to permit its issue.

Remedies. In Venice, the custom is to open or widen the top of the flue, rounding it in the true form of a funnel. In other places the contrary is practised; the tops of the flues being narrowed inwards, so as to form a slit for the issue of the smoke, as long as the breadth of the funnel, and only four inches wide. This seems to have been contrived on a supposition that the entry of the wind would thereby be obstructed; and perhaps it might have been imagined, that the whole force of the rising warm air being condensed, as it were, in the narrow opening, would thereby be strengthened, so as to overcome the resistance of wind. This, however, did not always succeed; for when the wind was at north-east and blew fresh, the smoke was forced down by fits into the room where Dr. Franklin commonly sat, so as to oblige him to shift the fire into another. The position of the slit of this funnel was indeed north-east and south-west. Perhaps if it had lain across the wind, the effect might have been different. But on this we can give no certainty. It seems a matter proper to be referred to experiment. Possibly a turncap might have been serviceable, but it was not tried.

With all the science, however, that a man shall suppose himself possessed of in this article, he may sometimes meet with cases that shall puzzle him. "I once lodged," says Dr. Franklin, "in a house at London, which in a little room had a single chimney and funnel. The opening was very small, yet it did not keep in the smoke, and all attempts to have a fire in this room were fruitless. I could not imagine the reason, till at length observing that the chamber over it, which had no fireplace in it, was always filled with smoke when a fire was kindled below, and that the smoke came through the cracks and crevices of the wainscoat, I had the wainscoat taken down, and discovered that the funnel which went up behind it had a crack many feet in length, and wide enough to admit my arm; a breach very dangerous with regard to fire, and occasioned probably by an apparent irregular settling of one side of the house. The air entering this breach freely, destroyed the drawing force of the funnel. The remedy would have been, filling up the breach, or rather rebuilding the funnel; but the landlord rather chose to stop up the chimney.

"Another puzzling case I met with at a friend's country-house near London. His best room had a chimney in which, he told me, he never could have a fire, for all the smoke came out into the room. I flattered myself I could easily find the cause and prescribe the cure. I opened the door, and perceived it was not want of air. I made a temporary contraction of the opening of the chimney, and found that it was not its being too large that caused the smoke to issue. I went out and looked up at the top of the chimney: Its funnel was joined in the same stack with others, some of them shorter, that drew very well, and I saw nothing to prevent its doing the same. In fine, after every other examination I could think of, I was obliged to own the insufficiency of my skill. But my friend, who made no pretension to such kind of knowledge, afterwards discovered the cause himself. He got to the top of the funnel by a ladder, and looking down found it filled with twigs and straw cemented by earth and lined with feathers. It seems the house, after being built, had stood empty some years before he occupied it; and he concluded that some large birds had taken the advantage of its retired situation to make their nests there. The rubbish, considerable in quantity, being removed, and the funnel cleared, the chimney drew well, and gave satisfaction."

Chimneys whose funnels go up in the north wall of a house, and are exposed to the north winds, are not so apt to draw well as those in a south wall; because, when rendered cold by those winds, they draw downwards. Chimneys enclosed in the body of a house are better than those whose funnels are exposed in cold walls. Chimneys in stacks are apt to draw better than separate funnels, because the funnels that have constant fires in them warm the others in some degree that have none.

Smoke-consuming. In manufacturing towns, where a great deal of fuel is used, it is of the utmost consequence to prevent, if possible, the production of smoke, so as not only to get quit of a great source of annoyance, but also to prevent the injury which it occasions to buildings; indeed to prevent the deterioration of property which in general occurs. Hence the clauses in acts of Parliament and in many police bills, compelling proprietors of steam engines, &c., to consume their smoke, if practicable; as also the numerous attempts which have been made to accomplish this object. Of course, if it could be done without an extra expenditure of fuel, so much the better; if with a saving of fuel, then the advantages to be gained are immense.

Numerous methods have been recommended, and many patents have been secured for accomplishing this desirable object. The principle of most of them depends on causing the smoke, immediately when given off from the coal, when fresh put on the fire, to pass over the half-burned or charred fuel, and thus be consumed.

Smoke is merely carbonaceous matter evolved from fuel; for when the whole of the inflammable gaseous product is not brought into contact with air at a proper degree of heat, it is not burned, and therefore escapes in the state of smoke. Now it is evident, that if that smoke or carbonaceous particles, as it flows over the burning fuel, be supplied with air, it also will be burned, provided they are brought together at a high temperature; but this is not done in the usual way of combustion, because the air passing up from the ash pit through the fuel, is almost entirely deprived of its oxygen before it reaches the upper part of the furnace. In addition to the air, therefore, which is requisite for the combustion of the fuel, air must also be admitted *above the fire* for the consumption of the smoke.

The most common method in practice for consuming smoke is, instead of throwing the fuel back into the furnace, to place it always on the dead plate or charring plate at the mouth, gradually pushing it on upon the bars, as it is charred, or deprived of its bituminous principle, and again supplying more on the dead plate, which is in general inclined, so as to allow the fuel placed on it to fall, and come into contact with that on the bars. For the success of this process, air must be admitted into the furnace, above the fuel, so as to mix with the flame and smoke; but this is attended with disadvantage, for being cold, it not only acts injuriously, as in lessening the production of steam, but by bringing down the temperature, prevents the action on the smoke itself, which is consequently not all destroyed. Hence the practice of heating the air to be thus admitted. When this is done by an additional fire, though the smoke may to a certain extent be consumed, yet it is attended with expense; but this is obviated in a great measure by the introduction of tubes into the flues or chimney, one end communicating with the atmosphere, the other terminating in the furnace, over the fuel, by which the air that passes through them derives a part of that heat which is otherwise carried up the vent.

This method of preventing smoke has not been attended with the success at first expected from it, as is proved by its not having come into general use. Perhaps one source of failure is the difficulty of getting the firemen to supply the coal carefully on the front of the furnace; and hence it has been recommended to employ hoppers, by which the coal is always thrown on the dead-plate; but even when these are used, the consumption of smoke is not complete. As to the heating of the air, by passing it through tubes in the chimney or vent, one great objection to them is the powerful influence they have over the draught. It is well known, that when cold air is allowed to rush into the chimney, the draught is instantly diminished. Now these tubes must operate in the same way; for though the air does not mingle with that in the vent, yet by withdrawing heat from it, it must reduce its temperature, and thus prevent it from being forced up.

By far the most effectual method of consuming smoke is that lately recommended and patented by Ivison. It consists in throwing steam into the fore-part of the furnace, *above the fuel*, by means of a fan-shaped distributor, in the front of which are small apertures, varying in size and number, according to the width of the furnace and the pressure of the steam. In general they are from five to eight or ten in number, and about an eighth or a twelfth of an inch in diameter. The quantity of steam thus admitted is very trifling; and by its passage through the flame and smoke given off from the coals on the charring-plate, it instantly causes the disappearance of the smoke, and accordingly none whatever escapes from the chimney-top, except just when fresh coal is thrown in, and then it is barely perceptible, and only for a few seconds.

When applied to furnaces with boilers, steam is easily procured, by taking from the top of the boiler a small tube, which is carried into the furnace, and connected with the distributor, and by means of a stop-cock the supply is regulated. In cases where there is no boiler, a very small one must be erected, which can be placed on some part of the furnace, and will thus give off steam without any extra expenditure of fuel.

The most remarkable circumstance attending the use of this patent process, is the almost total absence of draught through the ash-pit, consequently little or no air passes up through the fire, while there is a rush of air *over the surface of the fuel*. Hence the necessity of allowing air to flow in by the door of the furnace, or, which is better, by means of tubes placed in the chimney or flues, by which it is heated previous to its entrance; because, as before stated, the admission of cold air must have a prejudicial effect. It is evident from this, that the combustion must proceed almost entirely by air supplied on the surface. Indeed, when properly applied, the supply of air through the ash-pit is almost reduced to nothing; and accordingly the fire can be kept in good condition, even though the ash-pit is closed in front.

In addition to the consumption of smoke, the application of steam in this way is attended with another advantage; the saving of fuel, which is certainly a great recommendation in its favour. Different statements have been given of the amount of saving effected; but if we can place reliance in the reports given by the patentee, it seems to be considerable.

Watt, from his numerous experiments, concluded, that for each pound of coal (English caking) consumed, rather more than eight pounds of water could be evaporated, thus requiring about eight pounds of coal for the cubic foot of water. Since his time, however, improvements in the construction of furnaces have been introduced, which have increased the amount of evaporation.

Mr. Watt's maximum result with Wallsend caking coal, conducted with the greatest care, was 8.9 pound of water to the pound of coal. The lowest was 5.93, the mean 7.4.

Mr. Parkes of Warwick states the ordinary result with one pound of caking coal to be 7.5 pounds, evaporated from 212°, but by his improved method in the furnaces of other persons, it was 8.7, while by a similar mode with his own furnace, it was 10.32 pounds.

With one of the Cornish boilers, coated and covered with the greatest care, and in all other respects rendered as perfect as possible, the result was 11.8 pounds, and a similar result was more recently obtained by Henwood.

The following is a tabular view of the results of Watt and others, shewing the quantity of water evaporated, and the quantity of fuel required for the horse-power of an engine:

EXPERIMENTS.	lbs. water to 1 lb. of English coal.	lbs. English coal to cubic foot water, or horse-power per hour.	Cubic feet of water to 84 lb. English coal.	Cubic feet water to 112 lb. English coal.
Watt's average,..	7.4	8.4	10.	13.33
United Mines Loam (Ed. Phil Jour., July 1839),...	9.58	6.23	12.93	17.24
Parkes of Warwick's method,........................	10.32	6.03	13.9	18.5
Huel Towan (Ed. Phil. Jour., July 1839),..........	10.55	5.9	14.23	18.97
Mr. Henwood's experiment,..........................	11.87	5.32	15.8	21.

By the use of the Ivison patent, when properly applied, the amount of evaporation becomes much greater, as has been certified by repeated trials, by scientific men of eminence, as the following table shews. The experiments were conducted with Scotish coal; and considering the heat given out by it, as compared to English caking coal, to be as three to four, the results will shew the amount of evaporation, or, which is the same thing, the quantity of fuel, used in comparison with what is given in the preceding table.

EXPERIMENTS.	lbs. water to 1 lb. of *Scotish* coal.	lbs. water to 1 lb. of English coal.	lbs. English coal to cubic foot water, or horse-power per hour.	Cubic feet of water to 84 lb. English coal.	Cubic feet water to 112 lb. English coal.
Average of 8 experiments, certified April 13, 1839,....................	11.41	15.21	4.09	20.5	27.4
Average of 3 experiments, certified May 10, 1839,....................	13.94	18.58	3·35	25.	33.46
Average of 12 workings, certified July 1839,........................	13.25	17.66	3.52	23.91	31.78
Maximum result of do.,..............	14.72	19.62	3.12	26.47	35.3
Average of the four preceding lines,.	13.43	17.96	3.46	24.02	32.3

From the above tables it appears, that the greatest quantity of water evaporated by the pound of English coal is 11.37; the maximum result by Ivison's process is, using Scotish coal, 14.72; the average 13.43; which, if we consider the English to the Scotish as four to three, gives 17.9, or equal to only about 3.46 of English coal to the cubic foot of water or horse power of an engine, certainly by far the largest and most economical result on record.

That this mode of consuming smoke is accompanied with saving of fuel, is also proved by comparative trials made with and without the use of steam, on the same furnace, as is shewn by the following table:

Workings with the Patent.			
Date.	Time.	Period of day.	Pounds of Coal used.
Sept. 25, 1838.	5 h. 15 m.	P.M.	560
— 26, —	5 – 15 –	A.M.	449
— 27, —	5 – 15 –	A.M.	612
Average,.................558			

Workings without the Patent.			
Date.	Time.	Period of day.	Pounds of Coal used.
Sept. 25, 1838.	5 h. 15 m.	A.M.	812
— 26, —	5 – 15 –	P.M.	812
— 27, —	5 – 15 –	P.M.	812
Average,.................812			

For the same time, then, and for the same amount of work done, the consumpt of fuel, as shewn by the above table, is in the ratio of 812 to 540, or as 100 to 66, thus indicating a saving of about 33 per cent.

By the admission of steam into the furnace in this way of consuming smoke, the draught is prodigiously increased; hence the absolute necessity, when applied to furnaces having tall chimneys, of resorting to means to counteract it. It is remarkable that the damper in common use has comparatively little or no effect. The means found to answer best are the admission of cold air into the chimney, by apertures, which can be varied in size, according to circumstances; or when this is found not to be sufficient, to have covers to the ash-pit, by which the draught up through the bars may be prevented; for it is only when the draught is properly checked, and a due quantity of air admitted above the fuel, that none flows into the ash-pit. In furnaces to be erected for the purpose, the draught can be sufficiently checked, by making the chimney much narrower and shorter than those now in use. In fact, were it not for the necessity of having a vent to carry off the gaseous products, the chimney might be dispensed with, as the steam of itself creates sufficient draught to carry in air for the combustion. Hence one very great advantage, in addition to the many others, to be derived from this mode; as, independently of economy in fuel, there must be an immense saving in the outlay in constructing furnaces; the application of the steam-tube with its distributor costing very little.

Different opinions are entertained with regard to the *rationale* of this process. Some suppose that the steam merely acts mechanically, by carrying along with it a sufficient quantity of air to maintain the combustion; and that that air flowing *over* the fuel, not only carries on its consumption there, but, acting on the smoke, causes its combustion also, by which of course there is an additional supply of heat. Besides, as the upper part of the furnace is free from smoke, the radiation from the fire must have a more powerful effect on the bottom of the boiler, and those parts of it exposed in the flues being also free from soot, will more easily transmit the heat. If, however, we place reliance on the results of the trials stated above, and the names of the scientific gentlemen by whom they were conducted is a proof of their accuracy, it is difficult to conceive how so large a result should be obtained, were there no further action than the consumption of the fuel. It is generally admitted, that were the whole of the heat from coal undergoing combustion rendered available, about fourteen pounds of water would be evaporated on an average by each pound of coal. But this cannot be done, because part of the heat must necessarily pass off by the chimney; but even with this waste, the quantity of water evaporated by Scotish coal was in some trials beyond fourteen pounds. This has given rise to the idea, that the steam, in addition to its mechanical action of carrying air into the upper part of the furnace, acts also chemically, that in fact it is decomposed and consumed. It has been long known, that when steam is passed through tubes stuffed with incandescent carbon, it is decomposed, and resolved into gaseous products. In a paper published by Dr. Fyfe in the *Edinburgh Phil. Journal*, 1837, it is shewn, that these gaseous products are not carbonic acid and carburetted hydrogen, as at one time supposed, but carbonic oxid and pure hydrogen. Now a similar decomposition may be effected on the steam in the Ivison process; for when it is brought into contact with the carbonaceous matter of the smoke, as given off at a high temperature from the coal on the charring-plate, it may be decomposed, and give, by its action on the smoke, carbonic oxid and hydrogen; and these being freely supplied with air, will be burned, and by their combustion give out an additional supply of heat, and it is well known that the heat given forth by hydrogen is very great. If this explanation be the correct one, (and it is strengthened by the fact, that when the coal is thrown far back in the furnace, so as to be beyond the influence of the steam, it is not consumed), then the smoke is not burned by the direct action of the air, but by first getting oxygen from the steam, so as to form carbonic oxid, and which oxid then receives oxygen from the atmosphere. An additional quantity of oxygen is thus required; and hence most probably the additional amount of heat evolved by the process.

Smoke-Silver. Lands were held in some places by the payment of the sum of sixpence yearly to the sheriff, called *smoke-silver* (Par. 4. Edw. VI.) Smoke-silver and smoke-penny are to be paid to the ministers of divers parishes as a *modus* in lieu of tithe-wood; and in some manors formerly belonging to religious houses, there is still paid, as appended to the said manors, the ancient Peter-pence, by the name of *Smoke money*. (Twisd. *Hist. Vindicat.* 77.)

SMOLENSKO, a circle or government of the eastern side of the Russian empire. It was formerly a part of Lithuania, and being gained by Russia in 1654, was then called White Russia. It is 10,980 square miles in extent, and contains 1,031,860 inhabitants, who are a mixture of Russians, Poles, and Jews. The city from which the province takes its name, stands in a valley, watered by the river Dnieper, which runs from east to west, and which is navigable for barges. The city, which has been rebuilt since the war, is now said to contain 15,000 inhabitants. For this population there are upwards of twenty churches. It has a cathedral for both Catholic and Greek Christians, an ecclesiastical seminary, and a gymnasium or high grammar school. It is a frontier and fortified town, and is remarkable for the great battle fought under the walls of the city, on the 16th of August 1812.

SMOLLETT, Tobias, whose writings have conferred distinguished honour upon the literature of his country, was descended from a family of considerable antiquity and opulence in the county of Dunbarton. His grandfather, Sir James Smollett of Bonhill, married a daughter of Sir Aulay Macaulay of Ardincaple, and by that lady had four sons, of whom Archibald, the youngest, was the father of the novelist. Archibald, who had been bred to no profession, died at an early age, leaving his family, consisting of a widow and three children, one of whom was an infant daughter, solely dependent on the bounty of his father. Smollett was born in 1721, in the old mansion-house of Dulquhurn, now a ruin. It is situated near the village of Renton, in the parish of Cardross. He was baptized Tobias George. The valley of the Leven, in which Smollett first saw the light, is surpassed by no other spot in our island, either for the grandeur of its scenery, or for the venerable associations with which it is connected. Nor was the ground which had been dignified by the tread of Wallace, Bruce, Napier, and Buchanan, dishonoured by the steps of Smollett.

From the grammar-school of Dunbarton, in which he had imbibed the rudiments of classical learning, Smollett was transferred to the University of Glasgow, where he prosecuted his more advanced studies with application and success. He was afterwards bound an apprentice to Mr. John Gordon, an eminent medical practitioner in that city. His elder brother James had adopted the profession of arms, an example which he was ambitious of following; but the old knight probably illustrated the advantages of the study of physic by reasoning which it would have been vain to controvert. When the young student had attained his eighteenth year, his grandfather died, without having made any adequate provision for the children of his youngest son. For this omission, his descendant furnished him with a niche in *Roderick Random*, more conspicuous than desirable.

The term of his apprenticeship having expired in his nineteenth year, and being now thrown upon his own resources, Smollett proceeded to London, where he attracted the notice of Lord Lyttelton. He had carried with him his tragedy of *The Regicide*, a juvenile performance of uncommon merit, but indifferently adapted to the purpose of representation. The various efforts which he ineffectually used to bring his play upon the stage, are detailed with indignant prolixity in the preface to that production, which he sent to the press some years afterwards, with a view of heaping confusion upon the lukewarm patronage of Lyttelton, and upon the shuffling evasions of Garrick. The patron and the manager were visited with many other tokens of his displeasure; but he lived to repent of the severe retribution which he had exacted for trivial wrongs, and made honourable mention of both in his History of England.

Thwarted in his expectations of earning fame and profit as a writer for the stage, Smollett was glad to accept the situation of surgeon's mate on board the Cumberland. That vessel, an eighty-gun ship, belonged to the armament which was bound to the West Indies, to join the fleet under the command of Admiral Vernon. Of the disastrous expedition against Carthagena, Smollett inserted an animated narrative in *Roderick Random*, and afterwards published a more detailed account in the *Compendium of Voyages*. When the discomfited squadrons returned to Jamaica, he quitted the service in disgust, and fixed his residence on the island. With Miss Lascelles, a fascinating West Indian, he there formed an acquaintance, which afterwards ripened into a matrimonial union. In 1746 he returned to London, which then resounded with acclamations occasioned by the victory at Culloden. With these were mingled some expressions of indignation at the atrocities inflicted by the royal army upon the helpless families of the insurgents. The voice of Smollett swelled the weaker cry, and he produced his pathetic ode, *The Tears of Scotland.* During the same year was published, *Advice, a Satire*. His next literary effort was *Alceste, an Opera*, which he wrote at the suggestion of Mr. Rich of Covent Garden Theatre. In consequence of some dispute with that patentee, the piece was withdrawn, and has never appeared in print. In 1747 he published *Reproof*, a second part of his former satirical production. The versification of these poems is sufficiently harmonious, and they abound with impetuous invective; but the rage of the satirist is without dignity, and rabid, without being infectious to readers of the present day. About this period he married Miss Lascelles, who was possessed of a small estate in the island of Jamaica; a precarious species of property, from which her husband appears to have derived little or no ultimate benefit.

In the year 1748, appeared *The Adventures of Roderick Random*. Fielding had already evinced himself a noble follower of Cervantes, and Smollett now stood forth, a no less worthy disciple of Le Sage. It must be owned that in this, and in all the other novels of Smollett, humour frequently appears in very loose attire. These scenes, however, like sheet-lightning, are alarming, but perfectly innocuous. The solemn depravity of Rousseau is more dangerous than the ludicrous indecorum of Smollett. In 1749, *The Regicide* was published by subscription. During the same year Smollett took the degree of M.D., in what University has not been ascertained. In 1750 he went to Paris, where he is supposed to have occupied himself in composing *The Adventures of Peregrine Pickle*, which were published in 1751. This admirable novel is disfigured by the introduction of an impertinent episode, in which are detailed, with unrelenting minuteness, the tedious intrigues of Lady Vane; who is said to have rewarded Smollett handsomely for the drudgery of compiling that durable record of her infamy. To compensate for this blemish, and for some rash sallies of humour, *Peregrine Pickle* is an absolute mine of character and adventure. The entertainment prepared by the learned physician, in the manner of the ancients, is perhaps the most irresistible piece of pleasantry that was ever devised by a ludicrous fancy. In his heroes and heroines, Smollett is not happy. For Random we have no respect; for Pickle we have no esteem; and Narcissa and Emilia are only the objects of appetite. Since the days of Tom Bowling and the Commodore, we have seen many sailors in print, who display an accurate and profound knowledge of technical *minutiae;* but their humour, if they have any, will not pass muster ashore, the medium through which it is conveyed being to uninstructed ears a mere succession of unintelligible gibberish. And these modern tars have all a striking family likeness to each other, with the exception of some sentimental rope-haulers of the American school, who are evidently monsters of the imagination. But each of Smollett's seamen, though drawn to the life, exhibits the strongest idiosyncrasy of character, and converses in a dialect which can be readily understood by those who have never seen a ship.[1]

The next production of Smollett's pen was "An Essay on the External Use of Water, in a letter to Dr. ——; with particular remarks upon the present method of using the Mineral Waters at Bath, in Somersetshire; and a plan for rendering them more safe, agreeable, and efficacious." 1752, 4to. At the period of this publication, Smollett resided at Bath, where he solicited professional employment; but the reputation of the satirist effectually marred the prospects of the physician. Despairing of success in his profession, Dr. Smollett now hired a house at Chelsea, where he entirely devoted himself to literary pursuits. The first fruits of his retirement were, *The Adventures of Ferdinand Count Fathom*, which appeared in 1753. The author's object in this production is, to set up the principal character "as a beacon for the benefit of the inexperienced and unwary." This personage is as much below, as one of Richardson's heroes is above, the standard of general nature. Few men are so virtuous or depraved as to have much sympathy with either; and it may very reasonably be questioned, whether any one was ever allured to virtue by viewing the unattainable perfections of Grandison, or deterred from vice by contemplating the superlative villany of Fathom. Besides, a picture of insipid excellence is at least harmless; but there is a moral insanity about some men, which leads them not only to delight in, but sometimes to emulate the achievements of fictitious desperadoes. The most striking passage in this novel, is the adventure in the forest, which creates terror as strong as the convulsions of laughter which reward the exploits of Trunnion and his myrmidons.

---

[1] The incident of Tom Pipes's concealing in his shoe his master's letter to Emilia, it is curious to trace to the following passage in Ovid's Art of Love; which has not escaped the laborious research of Hugo, *De prima Scribendi Origine*, p. 154.

Cum possit solea chartas celare ligatas,
Et vincto blandas sub pede ferre notas.

But although master of the passions of others, Smollett's own were under very indifferent control. A wretch, called Peter Gordon, whom he had maintained for a series of years, and in support of whose credit he had been prevailed upon to indorse notes, suddenly withdrew into the verge of the court, where, by means of insulting letters and messages, he provoked his benefactor to chastise him in such manner as to furnish grounds for an action of damages. The Hon. Alexander Hume Campbell, who was counsel for the plaintiff, having opened the proceedings with much gratuitous insolence towards the defendant and his witnesses, Smollett addressed a letter to that barrister, couched in very indignant and sarcastic terms, which afterwards found its way into the fifth volume of the European Magazine. This infamous prosecution terminated in the discomfiture of Gordon, but the issue of Smollett's dispute with Campbell is involved in obscurity. In the beginning of the year 1755, Smollett published his translation of Don Quixote, which was executed amid the anxiety of pecuniary embarrassment, and for which he had been paid by advance. This version is infinitely more spirited and elegant than that of his immediate predecessor Jarvis. But if Smollett has surpassed Motteux in maintaining the solemn fatuity of the knight, he is less happy in rendering the proverbial humour of the squire; for the corresponding phrases in English had already been appropriated, and he was reduced to the necessity of alteration, when there was no room for improvement. After the publication of Don Quixote, Smollett paid a visit to his native country. Upon his return to England, he undertook the superintendence of the Critical Review. The editorship of that journal involved him in a thousand vexatious disputes with persons who were utterly unworthy of being promoted to the rank of his antagonists. A contemptuous critique on the Rosciad, of which he was entirely innocent, provoked the spleen of Churchill, whose brief career was a perpetual crusade against genius and virtue, and whose coarse and rancorous effusions are now consigned to merited oblivion; for posterity has not realized the hopes of an undying name, so confidently expressed by the reverend bard, who proposed to annihilate the reputation of Pope, and who launched his slight javelins at the massy buckler of Johnson.

In 1757, Smollett published a popular compilation, entitled *A Compendium of Authentic and Entertaining Voyages.* 7 vols. 12mo. During the same year was performed and printed *The Reprisal*, a comedy in two acts. The characters in this piece are strongly marked, and the dialogue is extremely spirited, but the situations are conceived with little dramatic artifice; a species of knowledge which often enables the humble retainer of a playhouse to concoct a drama, which shall be admirably well adapted for the stage, and yet prove not more entertaining in the closet than a book of arithmetic. In the same year was published the "Complete History of England, deduced from the Descent of Julius Cæsar to the Treaty of Aix-la-Chapelle, 1748, containing the transactions of one thousand three hundred and three years." 4 vols. 4to. This surprising effort of industry and genius, is said to have been begun and completed in the course of fourteen months. If not the most accurate and philosophical of historians, Smollett yields to few in the unaffected elegance of his style, and in the graceful animation of his narrative. He had been bred a Whig, and whatever were the motives that led to the political tergiversation which is manifested in this work, it would be uncharitable to suppose that they were those of self-interest; a consideration which does not seem to have influenced any one action of his life.

In 1759, an article appeared in the Critical Review, animadverting in strong terms upon the conduct of Admiral Knowles, who had written a pamphlet to vindicate himself from the popular odium which attached to his character, in consequence of his share in a secret expedition to the French coast, which was planned and miscarried in 1757.[1] The admiral having commenced a prosecution against the printer, of which the avowed object was to induce the writer to declare himself, and give him satisfaction of another kind, Smollett, in this dilemma, solicited the good offices of his friend Wilkes, whose rhetoric made no impression on the incensed commander. At this juncture, Smollett stepped boldly forth, and proclaimed himself the author of the obnoxious article, offering the aggrieved party any satisfaction that he might desire. Upon this declaration, the magnanimous flag-officer immediately withdrew his action against the printer, and entered a fresh suit against the reviewer. The result of the action was, that Smollett was fined one hundred pounds, and sentenced to three months imprisonment in the King's Bench.

To cheer the gloom of his confinement, this indefatigable writer employed himself in composing *The Adventures of Sir Launcelot Greaves*, which first appeared in the *British Magazine* for 1760 and 1761, and was published in a separate form in 1762. The eye of criticism has always looked coldly upon this performance. Although it is one of those works, of which the execution must be admitted to surpass the conception, the story of the modern Don Quixote is no such incredible figment as it has been pronounced. Sir Launcelot Greaves is represented as a person of diseased understanding; and who shall set bounds to the vagaries of insanity? Nor does Captain Crowe appear to act out of character, in becoming a candidate for the honours of chivalry. For that original is in a state of happy ignorance concerning all terrestrial affairs; and the profession of a knight-errant appears to his unsophisticated understanding to be as lawful a calling as that of a tide-waiter; and it is one which is not at all discordant with the headlong courage and extravagant generosity of a British seaman.

To the modern part of Universal History, which was begun in 1759, and completed in 1764, Smollett contributed the histories of France, Italy, and Germany. In 1761 had appeared the first number of his *Continuation of the History of England*, which he finished in 1765; the narrative comprehending the transactions down to that period.

Upon the accession of George III., Smollett appeared in the character of a political partisan, and drew his pen in defence of the administration of Lord Bute, in a weekly paper, entitled *The Briton.* But being speedily tired of protecting from obloquy a minister who was indifferent to public opinion, he retired from the strife, leaving his antagonist, *The North Briton*, master of the field. This contest terminated an intimacy of long standing between Smollett and Wilkes. Notwithstanding his inferiority in talents, that demagogue had some decided advantages over his opponent. Wilkes was a cool political pugilist, who gathered courage from the applauses of the mob; while Smollett was greeted with a general burst of popular execration, which worked him into a phrensy that deprived him of his strength.

---

[1] The offensive words were, "He is an admiral without conduct, an engineer without knowledge, an officer without resolution, and a man without veracity." Knowles was one of the heroes of Carthagena, at which memorable expedition he commanded the Weymouth, of 60 guns.

Smollett's name stands in the title-page of a translation of the works of Voltaire, and also in that of a compilation, entitled *The Present State of all Nations.* These works, to which he contributed sparingly, were published in 1763. In that year he sustained an irreparable loss in the death of his only child, a daughter named Elizabeth, who had attained the fifteenth year of her age. This calamity threw an impenetrable gloom over the brief remainder of his life. In the hope of dissipating his own grief and that of his wife, by change of scene, he passed over into France; in which country, and in Italy, he resided for two years. In 1766, he published his *Travels through France and Italy.* This production displays his usual acuteness of observation, and felicity of expression, but he appears to have contemplated every object through the distorted medium of disease and lacerated feelings. Sterne, who had met the bereaved father abroad, took an opportunity of exulting over the infirmities of rival genius in his Sentimental Journey.

In 1766, Smollett visited Scotland for the last time. At this period, he was a martyr to asthma and rheumatic pains, and afflicted with a virulent ulcer on his arm. In the following year, while residing at Bath, he enjoyed a short interval of convalescence, during which he wrote *The Adventures of an Atom.* In this political romance, he has blended, with greater dexterity than judgment, the reckless jollity of Rabelais with the withering sarcasm of Swift. With much wit and humour, this production betrays great physical indelicacy, a latent ferocity of sentiment, and an unqualified abhorrence of the lower order of the community, which is far from edifying. It may here be remarked, that the learning which is scattered through the fictitious narratives of Smollett, would, with proper management, make a most imposing show in works of much graver pretensions. Neither does he ever, like Fielding, hover on the verge of pedantry; nor resort to the disingenuous artifice of dazzling unlettered eyes with borrowed erudition, like Sterne, who had cool effrontery enough to express his sovereign contempt of literary larceny, in the unacknowledged words of Burton.[1]

After the publication of this romance, Smollett's complaints returned with increased violence, and his medical friends declared that his only chance of life lay in a more salubrious climate. To the great he never applied in vain, for he never applied at all. His friends however made some fruitless efforts to interest the ministry in his behalf. But from Smollett was sternly withheld that bounty which has often, before and since, been lavished with a prodigal hand upon the most worthless and foolish of mankind. With a constitution worn to the dregs in the service of literature, and with a purse which had been emptied in the lap of indigence, Smollett proceeded to Italy in 1770.

The last, and perhaps the best of all his works, was *The Expedition of Humphrey Clinker*, published in 1771. Each character in the galaxy of originals which are there pourtrayed, may submit without apprehension to Ben Jonson's test of humour:

> When some one peculiar quality
> Doth so possess a man, that it doth draw
> All his affects, his spirits, and his powers,
> In their conflictions, all to run one way,
> This may be truly said to be a humour.

Having bequeathed this legacy to the public, Smollett died at Monte Nero, a village in the neighbourhood of Leghorn, on the 21st of October 1771, in the fifty-first year of his age. A monument was erected to his memory by his widow, and a cenotaph on the banks of the Leven by his cousin, Mr. Smollett of Bonhill.

To a handsome person, and an address at once dignified and engaging, Smollett added colloquial powers of the highest order. His irascible passions were strong, but his social affections were not less so. If it is remembered that his personal and political prejudices were intense, let it not be forgotten that zealous friendship and ardent patriotism were among the number. He was improvident, for his hand was only closed to the necessities of others when he had nothing to bestow. He was a man of undaunted resolution, and lofty independence of mind. He was vindictive, but not implacable, and melted at the first appearance of contrition in those who had injured him. He was jealous of his fame, his sole possession, but he envied that of no other man, whether deserved or otherwise. Of Smollett, as an author, it may be truly said, that of the many different kinds of composition which he has attempted, there is none to which he has not communicated peculiar graces; nor can we hesitate for a moment in adding his name to the scanty list of those who have extended the limits of intellectual enjoyment.[2]

SMOOTH ISLAND, on the east coast of Van Diemen's Land, in Norfolk Bay, about three-quarters of a mile long.

SMUGGLERS, persons who import or export prohibited goods without paying the duties appointed by the law. When we consider the nature, and still more the history of mankind, we must allow that the enacting of severe penal laws is not the way to prevent crimes. It is indeed much to be wished that there were no such thing as a political crime; for the generality of men, but especially the poorer classes, not discerning the propriety or utility of such laws, consider them as oppressive and tyrannical, and never hesitate to violate them when they can do it with impunity. Instead therefore of punishing smugglers, it would be much better to remove the temptation. But the high duties which have been imposed upon the importation of many different sorts of foreign goods, in order to discourage their consumption in Great Britain, have in many cases served only to encourage smuggling; and in all cases have reduced the revenue of the customs below what more moderate duties would have afforded. The saying of Dr. Swift, that in the arithmetic of the customs two and two, instead of making four, make sometimes only one, holds perfectly true with regard to such heavy duties, which never could have been imposed, had not the mercantile system taught us, in many cases, to employ taxation as an instrument, not of revenue, but of monopoly.

The bounties which are sometimes given upon the exportation of home produce and manufactures, and the drawbacks which are paid upon the re-exportation of the greater part of foreign goods, have given occasion to many frauds, and to a species of smuggling more destructive of the public revenue than any other. In order to obtain the bounty or drawback, the goods, it is well known, are sometimes shipped and sent to sea, but soon afterwards clandestinely relanded in some other part of the country.

Heavy duties being imposed upon almost all goods imported, our merchant importers smuggle as much, and make entry of as little as they can. Our merchant exporters, on the contrary, make entry of more than they export; sometimes out of vanity, and to pass for great dealers in goods which pay no duty; and sometimes to gain a bounty or a drawback. Our exports, in consequence of these different frauds, appear upon the custom-house books greatly to overbalance our imports; to the unspeakable comfort of those politicians who measure the national prosperity by what they call the balance of trade.

---

[1] See Scott's Biographical Memoirs of eminent Novelists, vol. i. p. 294.

[2] For more circumstantial details of the life of Smollett, the reader is referred to the narratives of Dr. Anderson and Dr. Moore.

SMYRNA, a large commercial city of Asia Minor, situated at the head of a long and winding gulph on the western coast of the Grecian Archipelago, and, with the exception of Constantinople, the most important sea-port of the Turkish empire. It has an imposing appearance from the sea; and its bay, besides numerous small craft, is frequented by ships from the chief ports of Europe. The present town is about four miles in circuit, and extends about a mile along the water. The bay is so completely landlocked, that nothing is seen from the town but the projecting points that enclose it. The interior of the city is not so inviting as its aspect from without. The streets are narrow, dirty, and ill-paved, and the houses are for the most part unseemly wooden edifices; but though their external appearance is rather gloomy, the situation of those built along the water is delightful, as they have all gardens attached to them, at the foot of which are summer-houses overlooking the sea. Of late years Smyrna has been greatly improved, and well-built hotels and excellent lodging-houses now invite the traveller to a city where, we are assured, not only the "decencies of house-keeping and house-furnishing, but the comforts and luxuries of life flow in abundantly from London and from Paris." The houses of painted wood, which were so unworthy of its ancient fame, are rapidly giving way to palaces of stone, which are rising in all directions; and in the course of a few years Smyrna will really be an elegant city, with every indication of prosperity and opulence. The bazaars, though well provided with goods, are by no means splendid in their structure. There are two very fine caravanseras, enclosing square courts, which, being covered with cupolas, make a handsome appearance. The shops are also arched over, and are very fine. The principal buildings are the mosques, the baths, the inns, and the market-place. Some of the mosques are very noble edifices; and likewise the inns, as already remarked. At the east end of the city is a large hill, about three quarters of a mile in circumference, on which the castle was built. The edifice appears to have been the work of the Genoese, and to have been by no means magnificent. Along its circumference, however, may still be traced the remains of a very thick and strong wall, apparently that of the ancient castle, and corresponding in its appearance with another which appears to have surrounded the whole city. Behind the city is an extensive plain, most luxuriant and highly cultivated, and crowned with numerous olive-trees; it is watered by a small river, from fifty to a hundred yards broad, which contains little water, unless when artificially confined. Of the former magnificence of this ancient city, scarcely any traces are now to be seen. The reason of this is stated by Pococke to be, that the ancient structures have been demolished to furnish materials for modern ones; and a more recent traveller, Arundel, assigns much the same reason. The present does not occupy the site of the ancient city. The latter was situated on the hills, to the south of the present town; but the earthquakes to which it is subject, and by which it was more than once nearly destroyed, together with the greater convenience of trade, occasioned its removal to the plain below, and to the lower declivities of the mountains; and accordingly it is observed by Mr. Arundel, that "few of the Ionian cities have furnished more relics of antiquity, or of greater merit, than Smyrna. But the convenience of transporting them, with the number of investigations, have exhausted the ruins; it is therefore not at all wonderful, that of the stoas and temples, the very ruins have vanished; and it is now extremely difficult to determine the sites of any of the ancient buildings, with the exception of the stadium, the theatre, and the temple of Jupiter Acræus, which was within the Acropolis." Of the stadium here mentioned, the ground-plan only remains, stript of its marble seats and decorations; and only the foundations can be seen of the splendid theatre, built on the slope of a hill, the site of which is now covered with houses. On a gateway belonging to the castle is a colossal statue of very fine workmanship, though much mutilated, which has been supposed to be that of the Amazon Smyrna, from which the city is reported to have derived its name. Marks of a very extensive aqueduct may also be traced, though a late traveller doubts of its very high antiquity.

Smyrna is increasing in population and in wealth. It is a great commercial emporium, and a crowded resort of merchants from all countries, with their various costumes, language, and religion. It is the most general entrepôt for the productions of the Levant, and its port is crowded with ships from the most distant ports. It has a safe and capacious roadstead, where there is good anchorage, and where the largest ships can load and unload close to the wharfs. Nearly every power in Europe has a consul at Smyrna, who is vested with more than ordinary authority. There are about twenty commercial houses at Smyrna; and the Venetians, Genoese, and other Italians, the Dalmatians, Dutch, French, and Americans, have also establishments. No other town in Asiatic or European Turkey has so great a trade. All classes are engaged in business. The higher order of Franks deal often to a great extent; while the lower classes, consisting of persons from nearly every country in the Mediterranean, obtain employment as boatmen, carpenters, tailors, shoemakers, and the trade is carried on by Jews, mostly brokers. The Greek dealers are in general petty shopkeepers, very cunning, and not remarkably trustworthy. The Jews are liable to the same objections, but they often guarantee each other's transactions. The Armenians are the largest traffickers, but though usually strict at a bargain, they are generally solvent, and honourable as well as honest. The Turkish dealers, are, however, superior to them in all moral qualities, as they are inferior in means and in talents for business; yet they sometimes deal largely, and their bond is punctually discharged the day it becomes due.

The largest article of import is coffee, the favourite beverage of all classes in Turkey and Western Asia. The chief supply is derived from America, from England, France, also in smaller quantities from Holland, Trieste, Leghorn, and Genoa. Sugar is the next article in importance, and the supply is furnished by the same countries which supply coffee. Indigo is exclusively imported from England. The exports from Smyrna consist of silk from Brassa, about two hundred miles from Smyrna, which is forwarded by caravans to this port, and is the richest article of export. This branch of trade promises to increase, as there is so great a demand for the raw material in Britain. Opium is largely exported, particularly to America, whence it has found its way to China, though the trade is now vigorously proscribed by the Chinese authorities, and has caused the expulsion of the English from the port of Canton. Drugs and gums are exported to the English market; galls for England, Germany, France, and Valona or Avlona, a sea-port in European Turkey at the entrance of the Gulf of Venice. British shipping receives full cargoes of this more than of any other article, with the exception of fruit. These, with madder, sponges, olive-oil, wax, hare-skins, goats and sheep's wool, complete the articles of export. Figs and raisins may be considered as the great staple article of Smyrna, which are celebrated for their excellence, and are exported in large quantities. The exports from this country to Smyrna are increasing. From 1827 to 1830, they had increased from L.531,704 to L.1,139,616, nine-tenths of which were cotton goods, for which there is a great desire, being cheaper than those from any other quarter; and the late commercial treaty concluded with Turkey in 1838 will extend this trade.

Smyrna is well supplied with provisions, with fish and fruit of all kinds, and with excellent wines from the interior or from the islands. Of late years a great change has taken place in the manners and character of its inhabitants. Mr. Arundel, who resided many years in the place as British chaplain, has stated that numerous printing-presses, and journals in the different languages, viz. French, English, Greek, and Italian, have familiarised the inhabitants of Smyrna with the politics and literature of Europe. Even a few years ago, the Greek youths of Smyrna had no other means of acquiring knowledge, but very inferior day-schools and private instruction. There are now not only several seminaries, one dignified with the name of a college, for the education of the French youth of both sexes, but likewise for the Greeks there are various free schools, where numerous pupils not only learn the rudiments of knowledge, but also every branch of polite literature. There is a public dispensary, where persons of all nations are gratuitously relieved without regard to any distinction of religion. It is not easy to form an accurate account of the population. Mr. Arundel estimates the number of inhabitants from 100,000 to 120,000. There are twenty mosques, three Greek churches, two for Roman Catholics, one Armenian, one Protestant Episcopal, and one Dutch. The Jews have numerous synagogues, and the environs are adorned with cypress groves, the burial-places of the Mahometans.

Smyrna was one of the most celebrated cities in the ancient world, and claims, along with others, to be the birthplace of Homer. It is said originally to have been a colony from Ephesus, and soon attained to great prosperity. The original city was destroyed by the Lydians, and was rebuilt by Antigonus and Lysimachus, though on a somewhat different spot. It surpassed its former splendour: the streets were beautifully laid out, well paved, and adorned with porticoes. Under the Roman emperors, Smyrna, which was esteemed one of the most beautiful of the Ionian cities, was ruined by the desolations of the barbarians. It was captured by Tamerlane, and sacked, with great slaughter of the inhabitants. When the Turks gained undisputed possession of the Greek empire, and peace was restored, commerce again revived, owing to the favourable position of the place; and from that period it enjoyed almost uninterrupted repose, until the era of the Greek revolution. That event has now passed away, and Smyrna is prospering as the greatest commercial city in the Levant. Long. 27. 4. 45. E. Lat. 38. 29. N.

SNAFFLE, in the manege, is a very slender bit-mouth without any branches. It is much used in England, the true bridles being reserved for war.

SNAITH, a town in the Wapentake of Osgoldcross, in the West Riding of the county of York, one hundred and seventy-four miles from London. It stands on the navigable river Aire, in a pleasant situation. The inhabitants were in 1801, 688; in 1811, 743; in 1821, 834; and in 1831, 885; but the inhabitants of the whole parish are 8530.

SNAKE, in *Zoology*. See SERPENTS.

SNARES, a cluster of seven craggy islands in the South Pacific Ocean, discovered by Vancouver. Long. 166. 20. E. Lat. 48. 3. S.

SNEEK, a town in the Netherlands, in the province of Friesland, the capital of a circle of the same name. It is situated on a canal connected with Leuwarden, a place of much activity, having many saw and oil mills, and some manufactories of pottery ware, and exporting much corn. It contains two churches, a stadthouse, and 6455 inhabitants.

SNEEZING, a convulsive motion of the muscles of the breast, by which the air is expelled from the nose with much vehemence and noise. It is caused by the irritation of the upper membrane of the nose, excited by acrid substances floating in the air, or by medicines called *sternutatory*.

This irritation is occasioned either externally, by strong smells, or by dust floating in the air, and taken in by inspiration; or by sharp pungent medicines, as cresses and other sternutatories, which vellicate the membrane of the nose; or internally, by the acrimony of the lympha or mucus, which naturally moistens that membrane. The matter cast forth in sneezing comes primarily from the nose and throat, the pituitary membrane continually exuding a mucus; and, secondarily, from the breast, the trachea, and the bronchia of the lungs.

The practice of saluting the person who sneezed existed in Africa, among nations unknown to the Greeks and Romans. The accounts we have of Monomotapa inform us,[1] that when the prince sneezes, all his subjects in the capital are advertised of it, that they may offer up prayers for his safety. The author of the *Conquest of Peru* assures us, that the cacique of Guachoia having sneezed in presence of the Spaniards, the Indians of his train fell prostrate before him, stretched forth their hands, and displayed to him the accustomed marks of respect, while they invoked the sun to enlighten him, to defend him, and to be his constant guard.

Every body knows that the Romans saluted each other on these occasions: and Pliny relates,[2] that Tiberius exacted these signs of homage when drawn in his chariot. Superstition, whose influence can debase every thing, had degraded this custom for several ages, by attaching favourable or unfavourable omens to sneezing, according to the hour of the day or night, according to the signs of the zodiac, according as a work was more or less advanced, or according as one had sneezed to the right or to the left.[3] If a man sneezed at rising from table or from his bed, it was necessary for him to sit or lie down again. You are struck with astonishment, said Timotheus to the Athenians, who wished to return into the harbour with their fleet,[4] because he had sneezed; you are struck with astonishment, because among ten thousand there is one man whose brain is moist.

Polydore Virgil pretends, that in the time of Gregory the Great, there reigned in Italy an epidemic distemper, which carried off by sneezing all those who were seized by it; and that this pontiff ordered prayers to be made against it, accompanied by certain signs of the cross. But besides that there are very few cases in which sneezing can be considered as dangerous, and that it is frequently a favourable symptom,[5] it is evident, that we ought not to date from the sixth century the origin of a custom which loses itself in the obscurity of antiquity. Avicenna and Cardan aver that it is a sort of convulsion, which gives occasion to dread an epilepsy, and that this disease is endeavoured to be warded off by prayers. Clement of Alexandria considers it as a mark of intemperance and effeminacy, which ought to be proscribed; and he inveighs bitterly against those who endeavour to procure sneezing by external aid. Montaigne, on the contrary, explains this fact in a tone rather cynical. It is singular enough, that so many ridiculous, contradictory, and superstitious opinions, have not abolished those customary civilities which are still preserved equally among high and low; and which only the Anabaptists and Quakers have rejected, because they have renounced salutations in every case.

Among the Greeks sneezing was almost always a good omen. It excited marks of tenderness, of respect, and attachment. The genius of Socrates informed him by sneezing, when it was necessary to perform any action. The young Parthenis, hurried on by her passion, resolved to write to Sarpedon an avowal of her love; she sneezes in the most tender and impassioned part of her letter: this is sufficient for her; this incident supplies the place of an answer, and persuades her that Sarpedon is her lover. Penelope, harassed by the vexatious courtship of her suitors, begins to curse them all, and to pour forth vows for the return of Ulysses. Her son Telemachus interrupts her by a loud sneeze. She instantly exults with joy, and regards this sign as an assurance of the approaching return of her husband. Xenophon was haranguing his troops; a soldier sneezed in the moment when he was exhorting them to embrace a dangerous but necessary resolution. The whole army, moved by this presage, determined to pursue the project of their general; and Xenophon ordered sacrifices to Jupiter the preserver.

This religious reverence for sneezing, so ancient, and so universal even in the times of Homer, always excited the curiosity of the Greek philosophers, and of the rabbins. These last have spread a tradition, that, after the creation of the world, God made a general law to this purport, that every living man should sneeze but once in his life, and that at the same instant he should render up his soul into the hand of his Creator, without any preceding indisposition. Jacob obtained an exemption from the common law, and the favour of being informed of his last hour. He sneezed and did not die; and this sign of death was changed into a sign of life. Notice of this was sent to all the princes of the earth; and they ordained that in future sneezing should be accompanied with forms of blessing, and vows for the persons who sneezed.

Aristotle likewise remounts to the sources of natural religion. He observes, that the brain is the origin of the nerves, of our sentiments, our sensations, the seat of the soul, the image of the Divinity; that upon all these accounts, the substance of the brain has ever been held in honour; that the first men swore by their head; that they durst not touch nor eat the brains of any animal; that it was even a sacred word which they dared not to pronounce. Filled with these ideas, it is not wonderful that they extended their reverence even to sneezing. Such is the opinion of the most ancient and sagacious philosophers of Greece.

According to mythology, the first sign of life Prometheus's artificial man gave was by sternutation. This supposed creator is said to have stolen a portion of the solar rays; and filling with them a phial, which he had made on purpose, sealed it up hermetically. He instantly flies back to his favourite automaton, and opening the phial, holds it close to the statue; the rays still retaining all their activity, insinuate themselves through the pores, and set the fictitious man a-sneezing. Prometheus, transported with the success of his machine, offers up a fervent prayer, with wishes for the preservation of so singular a being. His automaton observed him, and, remembering his ejaculatious, was very careful, on the like occasions, to offer these wishes in behalf of his descendants, who perpetuated it from father to son in all their colonies.

SNIGGLING, a method of fishing for eels, chiefly used in the day time, when they are found to hide themselves near wears, mills, or flood-gates.

SNIPE. See ORNITHOLOGY.

SNOW, a well-known meteor, formed by the freezing of the vapour of water in the atmosphere. It differs from hail and hoar-frost, in being as it were crystallized, which they are not. This appears in examining a flake of snow by a magnifying glass; when the whole of it will appear to be composed of fine shining spicula diverging like rays from a centre. As the flakes fall down through the atmosphere, they are continually joined by more of those radiated spicula, and thus increase in bulk like the drops of rain or hailstones. Dr. Grew, in a discourse of the nature of snow, observes, that many parts thereof are of a regular figure, for the most part stars of six points, and are as perfect and transparent ice as any we see on a pond. Upon each of these points are other collateral points, set at the same angles as the main points themselves; among which there are divers other irregular, which are chiefly broken points, and fragments of the regular ones. Others also, by various winds, seem to have been thawed and frozen again into irregular clusters, so that it seems as if the whole body of snow were an infinite mass of icicles irregularly figured; that is, a cloud of vapours being gathered into drops, the said drops forthwith descend; upon which descent, meeting with a freezing air as they pass through a colder region, each drop is immediately frozen into an icicle, shooting itself forth into several points; but these still continuing their descent, and meeting with some intermitting gales of warmer air, or in their continual waftage to and fro, touching upon each other, some of them are a little thawed, blunted, and again frozen into clusters, or entangled so as to fall down in what we call flakes.

The lightness of snow, although it is firm ice, is owing to the excess of its surface, in comparison to the matter contained under it; as gold itself may be extended in surface till it ride upon the least breath of air.

The whiteness of snow is owing to the small particles into which it is divided; for ice, when pounded, will become equally white. An artificial snow has been made by the following experiment. A tall phial of aquafortis being placed by the fire till it is warm, and filings of pure silver, a few at a time, being put into it, after a brisk ebullition, the silver will dissolve slowly. The phial being then placed in a cold window, as it cools, the silver particles will shoot into crystals, several of which running together, will form a flake of snow, which will descend to the bottom of the phial. While they are descending, they represent perfectly a shower of silver snow, and the flakes will lie upon one another at the bottom, like real snow upon the ground.

According to Signor Beccaria, clouds of snow differ in nothing from clouds of rain, but in the circumstance of cold that freezes them. Both the regular diffusion of the snow, and the regularity of the structure of its parts, particularly some figures of snow or hail which fall about Turin, show that clouds of snow are acted upon by some uniform cause like electricity; and he endeavours to show how electricity is capable of forming these figures. He was confirmed in his conjectures by perceiving, that his apparatus for observing the electricity of the atmosphere never failed to be electrified by snow as well as rain. Professor Winthrop sometimes found his apparatus electrified by snow when driven about by the wind, though it had not been affected by it when the snow itself was falling. A more intense electricity, according to Beccaria, unites the particles of hail more closely than the more moderate electricity does those of snow, in the same manner as we see that the drops of rain which fall from thunder-clouds are larger than those which fall from others, though the former descend through a less space.

But we are not to consider snow merely as a curious and beautiful phenomenon. The Great Dispenser of universal bounty has so ordered it, that it is eminently subservient, as well as all the works of creation, to his benevolent designs. Were we to judge from appearances only, we might imagine, that so far from being useful to the earth, the cold humidity of snow would be detrimental to vegetation. But the experience of all ages asserts the contrary. Snow, particularly in those northern regions where the ground is covered with it for several months, fructifies the earth, by guarding the corn or other vegetables from the intenser cold of the air, and especially from the cold piercing winds.

Snow or ice water is always deprived of its fixed air, which escapes during the process of congelation. Accordingly, as some of the inhabitants of the Alps who use it for their constant drink, have enormous wens upon their throats, it has been ascribed to this circumstance. If this were the cause of these wens, it would be easy to remove it by exposing the snow-water to the air for some time. But several eminent physicians have rejected the notion that snow-water is the cause of these wens; for in Greenland, where snow-water is commonly used, the inhabitants are not affected with such swellings; and on the other hand, they are common in Sumatra, where snow is never seen.

SNOWDON, one of the highest mountains in Wales. It is within the county of Carnarvon, but extends to the borders of Merionethshire. The highest point of the range is 3571 feet above the level of the sea. The snow begins to fall on it in November, and is seldom melted till the middle of June. It is easily accessible in several directions. The view from the summit is extensive and grand, on a clear day, which does not often occur. The hills of Scotland are to be seen, with a part of the coast, as well as the Isle of Man; and the hills of Lancashire, Westmoreland, and Cumberland, and, in some very translucent days, the hills of Kerry, in Ireland, have been perceived. The mountain of Snowdon was held sacred by the ancient Britons.

SNYDERS, Francis, a Flemish painter, born at Antwerp in 1579, and bred under his countryman Henry Van Balen. His genius first displayed itself in painting fruit; he afterwards attempted animals, huntings, &c., in which he exceeded all his predecessors. He also painted kitchens, &c., and gave dignity to subjects that seemed incapable of it. He was made painter to Ferdinand and Isabella, archduke and duchess, and became attached to the house of the cardinal infant of Spain. The king of Spain and the elector Palatine adorned their palaces with huntings by this artist. Rubens, Jordaens, and Snyders, used to co-operate in the enriching of each other's pictures according to their several talents; and thus they became more valuable than if finished by either of them singly. Snyders died in 1657.

SOAGHIM, a town of Hindustan, in the Mahratta territories, province of Malwah, sixty miles west from Ooojain. Long. 74. 50. E. Lat. 23. 12. N.

SOANE River has its rise on the east of the table land of Omercuntire, in the province of Gundwana. It flows through Pindarah, where, being joined by numerous other streams from the north-east side of this mountainous territory, it proceeds in a northerly course to the Ganges, which it joins in the province of Bahar, after a winding course of about five hundred miles.

SOANK, a small river of Hindustan, in the province of Bahar, whence it flows in a southerly direction, and being joined by the small river Borkee, their united streams form the Braminy Nuddy river.

SOAP, a composition of caustic, fixed alkaline salt, and oil, sometimes hard and dry, sometimes soft and liquid; much used in washing, whitening linens, and by dyers and fullers. Soap may be made by several methods, which however all depend upon the same principle. The soap which is used in medicine is made without heat.

In manufactures where large quantities of it are prepared, soap is made with heat. A lixivium of quicklime and soda is made, but is less concentrated than that above referred to, and only so much that it can sustain a fresh egg. A part of this lixivium is to be even diluted and mixed with an equal weight of oil of olives. The mixture is to be put on a gentle fire, and agitated, that the union may be accelerated. When this mixture begins to unite well, the rest of the lixivium is to be added to it; and the whole is to be digested with a very gentle heat, till the soap be completely made. A trial is to be made of it, to examine whether the just proportion of oil and alkali has been observed. Good soap of this kind ought to be firm, and very white when cold; not subject to become moist by exposure to air, and entirely miscible with pure water, to which it communicates a milky appearance, but without any drops of oil floating on the surface. When the soap has not these qualities, the combination has not been well managed, or the quantity of salt or oil is too great, which faults must be corrected.

In soft or liquid soaps, green or black soaps, cheaper oils are employed, as oil of nuts, of hemp, of fish, &c. These soaps, excepting in consistence, are not essentially different from white soap. Fixed alkalies are much disposed to unite with oils that are not volatile, both vegetable and animal, since this union can be made even without heat. The compound resulting from this union partakes at the same time of the properties of oil and of alkali; but these properties are modified and tempered by each other, according to the general rule of combinations. Alkali formed into soap has not nearly the same acrimony as when it is pure; it is even deprived of almost all its causticity, and its other saline alkaline properties are almost entirely abolished. The same oil contained in soap is less combustible than when pure, from its union with the alkali, which is an inflammable body. It is miscible, or even soluble, in water, to a certain degree, by means of the alkali. Soap is entirely soluble in spirit of wine; and still better in aquavitæ sharpened by a little alkaline salt, according to an observation of Mr. Geoffroy.

The manufacture of soap in London first began in the year 1524; before which time this city was served with white soap from foreign countries, and with gray soap speckled with white from Bristol, which was sold for a penny a pound; and also with black soap, which sold for a halfpenny a pound.

Concerning the decomposition of soap by means of acids, we must observe, first, that all acids, even the weakest vegetable acids, may occasion this decomposition, because every one of them has a greater affinity than oil with fixed alkali. Secondly, these acids, even when united with any basis, excepting fixed alkali, are capable of occasioning the same decomposition; whence all ammoniacal salts, all salts with bases of earth, and all those with metallic bases, are capable of decomposing soap, in the same manner as disengaged acids are; with this difference, that the oil separated from the fixed alkali, by the acid of these salts, may unite more or less intimately with the substance which was the basis of the neutral salt employed for the decomposition.

Soap may also be decomposed by distillation, as Lemery has shown. When first exposed to fire, it yields a phlegm called by him a *spirit;* which nevertheless is neither acid nor alkaline, but some water which enters into the composition of soap. It becomes more and more coloured and empyreumatic as the fire is increased, which shows that it contains the most subtle part of the oil. It seems even to raise along with it, by help of the oil and action of the fire, a small part of the alkali of the soap: for, as the same chemist observes, it occasions a precipitate in a solution of corrosive sublimate. After this phlegm the oil rises altered, precisely as if it had been distilled from quicklime, that is, empyreumatic, soluble in spirit of wine, at first sufficiently subtle and afterwards thicker. An alkaline residuous coal remains in the retort, consisting chiefly of the mineral alkali contained in the soap, and which may be disengaged from the coal by calcination in an open fire, and obtained in its pure state.

Alkaline soaps are very useful in many arts and trades, and also in chemistry and medicine. Their principal utility consists in a detersive quality that they receive from their alkali, which, although it is in some measure saturated with oil, is yet capable of acting upon oily matters, and of rendering them saponaceous and miscible with water. Hence soap is very useful to cleanse any substances from all fat matters with which they happen to be soiled. Soap is therefore daily used for the washing and whitening of linen, for the cleansing of woollen cloths from oil, and for whitening silk and freeing it from the resinous varnish with which it is naturally covered. Pure alkaline lixiviums being capable of dissolving oils more effectually than soap, might be employed for the same purposes; but when this activity is not mitigated by oil, as it is in soap, they are capable of altering, and even of destroying entirely, by their causticity, most substances, especially animal matters, as silk, wool, and others; whereas soap cleanses from oil almost as effectually as pure alkali, without danger of altering or destroying; a circumstance which renders it very useful.

Soap was imperfectly known to the ancients. It is mentioned by Pliny as made of fat and ashes, and as an invention of the Gauls. Aretæus and others inform us, that the Greeks obtained their knowledge of its medical use from the Romans.

The following Table shows the quantity of Soap charged with the duties of Excise in the United Kingdom during the years 1835, 1836, *and* 1837, *and the number of Soap-makers during the same period, with the duties paid by them.*

	Quantities Charged.			Amount of Duty.								
	1835.	1836.	1837.	1835.			1836.			1837.		
Hard Soap, lbs.	148,806,207	146,539,210	140,822,611	£930,038	15	8	£915,860	18	4½	£880,141	6	3
Soft Soap........	12,103,109	13,358,894	11,794,834	50,429	12	5	55,662	1	2	49,145	2	10
Soap-makers....	450	432	402	1,800	0	0	1,728	0	0	1,608	0	0

The direct duty charged on hard soap is 1½d. per lb., and on soft soap 1d. per lb. Previously to June 1833, the duty on hard soap was 3d. per lb. The exorbitant amount of the tax, which was fully 100 per cent. on the cost, gave occasion to a great deal of smuggling, which is still carried on to some extent, and is facilitated by the injudicious regulation of taxing this commodity in one part of the kingdom, and leaving it untaxed in another; no duty being charged on soap manufactured in Ireland, and the duty being drawn back from such quantities as are imported into Ireland from Britain.

SOCAGE, in its most general and extensive signification, seems to denote a tenure by any certain and determinate service. And in this sense it is by our ancient writers constantly put in opposition to chivalry or knight-service, where the tenure was precarious and uncertain. The service must therefore be certain, in order to denominate it socage; as to hold by fealty and twenty shillings rent; or, by homage, fealty, and twenty shillings rent; or, by homage and fealty without rent; or, by fealty and certain corporal service, as ploughing the lord's land for three days; or, by fealty only without any other service; for all these are tenures in socage.

Socage is of two sorts: *free*-socage, where the services are not only certain but honourable; and *villein* socage, where the services, though certain, are of a baser nature. Such as hold by the former tenure are called, in Glanville and other subsequent authors, by the name of *liberi sokemanni*, or tenants in free-socage. The word is derived from the Saxon appellation *soc*, which signifies liberty or privilege, and, being joined to an usual termination, it forms *socage*, in Latin *socagium*, signifying a free or privileged tenure.

It seems probable that the socage-tenures were the relics of Saxon liberty; retained by such persons as had neither forfeited them to the king, nor been obliged to exchange their tenure for the more honourable, as it was called, but at the same time more burthensome, tenure of knight-service. This is peculiarly remarkable in the tenure which prevails in Kent, called *gavelkind*, which is generally acknowledged to be a species of socage-tenure; and its preservation from the innovations of the Norman conqueror is a fact universally known. And those who thus preserved their liberties were said to hold in free and common socage.

Society.

SOCIETY, a number of rational and moral beings, united for their common preservation and happiness. There are shoals of fishes, herds of quadrupeds, and flocks of birds. We call crows and beavers, and several other species of animals, *gregarious;* but it is hardly good English to say that they are *social.* It is only human society that can be regarded in this light, and the phenomena which it presents are highly worthy of our notice.

Mankind the only social beings subject to our observation.

Such are the advantages which each individual evidently derives from living in a social state; and so helpless does any human being appear in a solitary state, that we are naturally led to conclude, that if there ever was a period at which mankind were solitary beings, that period could not be of long duration; for their aversion to solitude and love of society would soon induce them to enter into social union. Such is the opinion which we are led to conceive when we compare our own condition as members of civilised and enlightened society with that of the brutes around us, or with that of savages in the earlier and ruder periods of social life.

A social and a savage state.

When we hear of Indians wandering naked through the woods, destitute of arts, unskilled in agriculture, scarcely capable of moral distinctions, void of all religious sentiments, or possessed with the most absurd notions concerning superior powers, and procuring means of subsistence in a manner equally precarious with that of the beasts of prey, we look down with pity on their condition, or turn from it with horror. When we view the order of cultivated society, and consider our institutions, arts, and manners, we rejoice over our superior wisdom and happiness. Man in a civilized state appears a being of a superior order to man in a savage state; yet some philosophers tell us, that it is only he who, having been educated in society, has been taught to depend upon others, that can be helpless or miserable when placed in a solitary state. They view the savage who exerts himself with intrepidity to supply his wants, or bears them with fortitude, as the greatest hero, and possessing the greatest happiness.

Whatever be the supposed advantages of a solitary state, certain it is that mankind, at the earliest periods, were united in society. Various theories have been formed concerning the circumstances and principles which gave rise to this union; but it has been sufficiently proved, that the greater part of them are founded in error; that they suppose the original state of man to have been that of savages; and that such a supposition is contradicted by the most authentic records of antiquity. For though the records of the earlier ages are generally obscure, fabulous, and imperfect, yet happily there is *one* free from the imperfections of the rest, and of undoubted authenticity, to which we may safely have recourse. This record is the Pentateuch of Moses, which presents us with a genuine account of the origin of man and of society.

SOCIETIES, associations voluntarily formed by a number of individuals for promoting knowledge, industry, or virtue. They may therefore be divided into three classes; societies for promoting science and literature, societies for encouraging and promoting arts and manufactures, and societies for diffusing religion and morality and relieving distress. These, however, are so numerous and fluctuating, that it would be difficult to offer any thing like an accurate account of them. The reader is referred for information on the subject to the articles, LONDON, DUBLIN, EDINBURGH, and the other towns and countries where these institutions have been established. We shall only notice the Royal Societies of London and Edinburgh.

The Royal Society of London is an academy or body of persons of eminent learning, instituted by Charles II., for the promoting of all the different branches of physical knowledge. The origin of this society is traced by Dr. Sprat, its earliest historian, no farther back than to "some space after the end of the civil wars" in the seventeenth century. The scene of the first meetings of the learned men who laid the foundation of it, is by him fixed in the university of Oxford, at the lodgings of Dr. Wilkins, warden of Wadham College. But Dr. Birch, on the authority of Dr. Wallis, one of its earliest and most considerable members, assigns it an earlier origin. According to him, certain worthy persons, residing in London about the year 1645, being "inquisitive into natural and the new and experimental philosophy, agreed to meet weekly on a certain day, to discourse upon such subjects, and were known by the title of *The Invisible* or *Philosophical College*." In the years 1648 and 1649, the company who formed these meetings was divided, part retiring to Oxford and part remaining in London; but they continued the same pursuits as when united, corresponding with each other, and giving a mutual account of their respective discoveries. About the year 1659 the greater part of the Oxford society returned to London, and again uniting with their fellow-labourers, met once, if not twice a-week at Gresham College, during term-time, till they were scattered by the public distractions of that year, and the place of their meeting made quarters for soldiers. On the restoration in 1660 their meetings were revived, and attended by a greater concourse of men eminent for their rank and learning. They were at last taken notice of by the king, who having himself a considerable taste for physical science, was pleased to grant them an ample charter, dated the 15th of July 1662, and afterwards a second dated 15th April 1663, by which they were erected into a corporation, consisting of a president, council, and fellows, for promoting natural knowledge; and to give their investigations, against which strange prejudices were entertained, every possible support, he sometimes honoured their meetings with his presence.

Their manner of electing fellows is by balloting. Their council consists of twenty-one, including the president, vice-president, treasurer, and two secretaries, eleven of which are continued for the next year, and ten more added to them; all being chosen on St. Andrew's day.

The services which this illustrious society has rendered to the public are very great. They have improved naval, civil, and military architecture; advanced the security and perfection of navigation; improved agriculture; and put not only this kingdom, but also Ireland, the plantations, &c., upon planting. They have registered experiments, histories, relations, observations, &c., and reduced them into one common stock; and have, from time to time, published those which they reckoned most useful, under the title of *Philosophical Transactions*, &c. They have a library adapted to their institution; towards which Mr. Henry Howard, afterwards duke of Norfolk, contributed the Norfolcian library, and which has been vastly increased by a continual series of benefactions.

The Royal Society of Edinburgh was incorporated by royal charter on the 29th of March 1783, and has for its object the cultivation of every branch of science, erudition, and taste. Its rise and progress towards its present state was as follows. In the year 1718 a literary society was established in Edinburgh by the learned Ruddiman and others, which in 1731 was succeeded by a society instituted for the improvement of medical knowledge. In the year 1739 the celebrated Maclaurin conceived the idea of enlarging the plan of this society, by extending it to subjects of philosophy and literature. The institution was accordingly new-modelled by a printed set of laws and regulations, the number of members was increased, and they were distinguished from that time by the title of *The Society for Improving Arts and Sciences*, or more generally by the title of *The Philosophical Society of Edinburgh*. Its meetings, however, were soon interrupted by the disorders of the country during the rebellion in 1745; and they were not renewed till the year 1752. Soon after this period the first volume of the Transactions of the Philosophical Society of Edinburgh was published, under the title of *Essays and Observations, Physical and Literary*, and was followed by other volumes of acknowledged merit. About the end of the year 1782, in a meeting of the professors of the university of Edinburgh, many of whom were likewise members of the Philosophical Society, and warmly attached to its interests, a scheme was proposed by the late Dr. Robertson, principal of the university, for the establishment of a new society on a more extended plan, and after the model of some of the foreign academies. It appeared an expedient measure to solicit the royal patronage to an institution of this nature, which promised to be of national importance, and to request an establishment by charter from the crown. The plan was approved and adopted; and the Philosophical Society, joining its influence as a body in seconding the application from the university, his majesty, as we have already observed, was graciously pleased to incorporate The Royal Society of Edinburgh by charter.

Members are elected by ballot. The general business of the society is managed by a president, two vice-presidents, with a council of twelve, a general secretary, and a treasurer. These officers are chosen by ballot annually on the last Monday of November. All public deeds, whether of a civil or of a literary nature, are transacted by this board, and proceed in the name of the president or vice-president.

As it was thought that the members would have a greater inducement to punctual attendance on the meetings of the society, if they had some general intimation of the nature of the subjects which were to be considered, and made the topics of conversation, it was therefore resolved to divide the society into two classes, which should meet and deliberate separately. One of these classes is denominated the *Physical Class*, and has for its department the sciences of mathematics, natural philosophy, chemistry, medicine, natural history, and whatever relates to the improvement of arts and manufactures. The other is denominated the *Literary Class*, and has for its department literature, philology, history, antiquities, and speculative philosophy. There are many valuable papers in the volumes that have been published of the *Transactions* of this society.

SOCIETY Isles, a cluster of isles, so named by Captain Cook in 1769. They are situated between the latitudes of 16. 10. and 16. 55. south, and between the longitudes of 150. 57. and 152. west. See POLYNESIA.

SOCINIANS, in church history, a sect of Christian heretics, so called from their founder Faustus Socinus. They maintain, "that Jesus Christ was a mere man, who had no existence before he was conceived by the Virgin Mary; that the Holy Ghost is no distinct person, but that the Father is truly and properly God. They own, that the name of God is given in the Holy Scriptures to Jesus Christ; but contend, that it is only a deputed title, which however in-

Socotara, Socrates.

vests him with an absolute authority over all created beings, and renders him an object of worship to men and angels. They deny the doctrines of satisfaction and imputed righteousness; and say that Christ only preached the truth to mankind, set before them in himself an example of heroic virtue, and sealed his doctrines with his blood. Original sin and absolute predestination they esteem scholastic chimeras. They likewise maintain the sleep of the soul, which they say becomes insensible at death, and is raised again with the body at the resurrection, when the good shall be established in the possession of eternal felicity, while the wicked shall be consigned to a fire that will not torment them eternally, but for a certain duration in proportion to their demerits."

This sect has long been indignant at being styled *Socinians*. They disclaim every human leader; and professing to be guided solely by the word of God and the deductions of reason, they call themselves *Unitarians*, and affect to consides all other Christians, even their friends the Arians, as *Polytheists*. Modern Unitarianism, as taught by Dr. Priestley, is, however, a very different thing from Socinianism, as we find it in the Racovian Catechism and other standard works of the sect.

SOCINUS, Lælius, the first author of the sect of the Socinians, was born at Sienna in Tuscany in 1525. Being designed by his father for the law, he began very early to search for the foundation of that science in the word of God; and by that study discovered that the Romish religion taught many things contrary to revelation. Being desirous of penetrating farther into the true sense of the scriptures, he studied Greek, Hebrew, and even Arabic. In 1547 he left Italy, to go and converse with the Protestants; and spent four years in travelling through France, England, the Netherlands, Germany, and Poland, and at length settled at Zürich. He by this means became acquainted with the most learned men of his time, who testified by their letters the esteem which they had for him; but as he discovered to them his doubts, he was greatly suspected of heresy. He however conducted himself with such address, that he lived among the capital enemies of his opinions, without receiving the least injury. He met with some disciples, who heard his instructions with respect; these were Italians who had left their native country on account of religion, and wandered about in Germany and Poland. He communicated likewise his sentiments to his relations by his writings, which he caused to be conveyed to them at Sienna. He died at Zürich in 1562. Those who were of sentiments opposite to his, and were personally acquainted with him, confess that his outward behaviour was blameless. He wrote a paraphrase on the first chapter of St. John; and other works are ascribed to him.

Socinus, *Faustus*, nephew of the preceding, and principal founder of the Socinian sect, was born at Sienna in 1539. The letters which his uncle Lælius wrote to his relations, and which infused into them many seeds of heresy, made an impression upon him; so that, knowing himself not innocent, he fled as well as the rest when the inquisition began to persecute that family. He was at Lyon when he heard of his uncle's death, and he departed immediately to take possession of his writings. He returned to Tuscany; and made himself so agreeable to the grand duke, that the charms which he found in that court, and the honourable posts which he filled there, hindered him for twelve years from remembering that he had been considered as the person who was to put the last hand to the system of divinity, of which his uncle Lælius had made a rough draught. At last he went into Germany in 1547, and paid no regard to the grand duke's advices to return. He stayed three years at Basel, and there studied divinity; and having adopted a set of principles very different from the system of Protestants, he resolved to maintain and propagate them; for which purpose he wrote a treatise *De Iesu Christo Servatore*. In 1579 Socinus retired into Poland, and desired to be admitted into the communion of the Unitarians; but as he differed from them in some points, on which he refused to be silent, he met with a repulse. He did not however cease to write in defence of their churches against those who attacked them. At length his book against James Palcologus furnished his enemies with a pretence to exasperate the king of Poland against him; but though the mere reading of it was sufficient to refute his accusers, Socinus thought proper to leave Cracow, after having resided there four years. He then lived under the protection of several Polish lords, and married a lady of a good family; but her death, which happened in 1587, so deeply afflicted him as to injure his health; and to complete his sorrow, he was deprived of his patrimony by the death of Francis de' Medici, great duke of Florence. The consolation which he found in seeing his sentiments at last approved by several ministers, was greatly interrupted in 1598; for he met with a thousand insults at Cracow, and was with great difficulty saved from the hands of the rabble. His house was plundered, and he lost his goods; but this loss was not so uneasy to him as that of some manuscripts, which he extremely regretted. To deliver himself from such dangers, he retired to a village about nine miles distant from Cracow, where he spent the remainder of his days at the house of Abraham Blonski, a Polish gentleman, and died there in 1604. All Faustus Socinus's works are contained in the first two volumes of the great collection entitled *Bibliotheca Fratrum Polonorum*.

SOCOTARA, an island of the Indian Ocean, about forty leagues to the eastward of Cape Guardafui. It is mountainous, with a bold shore and excellent harbours, and the inhabitants are in general civil to strangers. The principal produce is aloes. The town has a handsome appearance, the houses being built of stone, and some with several mosques. The residence of the king is in long. 53. 33. E. Lat. 12. 39. N.

SOCRATES. The name of Socrates is familiar to every one among his earliest classical recollections. Who has not heard of the Athenian sage, the great moralist of heathenism, and his persecution and constancy even to death? There is no name indeed which stands forth more conspicuously in the history of the philosophy, or of the religion, or of the general civilization of the ancient world. It marks a distinct era in the progress of the human race. The character of a great period in the history of man is concentrated, in fact, in the life and teaching of this extraordinary individual; and his name accordingly has descended to us with all the importance of the crisis itself at which he flourished; recommended as it is to our affection and admiration, not so much by the characteristics of his personality, as by the tradition of his influence and authority.

For when we come to consider his particular biography, we find our attention arrested by little that belongs merely to the individual. We read of a long life passed for the most part in uniform tenour within the walls of his native Athens; and until we come to its tragical close, scarcely distinguished in point of incident from that of the mass of his contemporaries. When, again, we ask for writings from which, as from the proper mirror of the philosopher's mind, we may collect some express lineaments of his character and teaching, we find nothing even on this ground on which our curiosity can fasten; so little have we derived that interest, which the mention of Socrates now awakens, from himself immediately; and so much, on the other hand, are we indebted for our acquaintance with this philosopher to a popular feeling preserving and handing down to us the name which represents the thought and character of an age.

The conjuncture of events at the time of Socrates was peculiarly favourable to the development of such a character. Socrates, born at Athens in the year 469 or 470 B.C. grew up to manhood during those years when Athens, standing on the proud eminence of her victories of Marathon and Salamis, was consolidating her power as a sovereign state and seat of empire. In the course of the fifty years which intervened between her triumphant resistance to the Persian invasion and the commencement of the Peloponnesian war, Athens, like Rome in her struggle with her Italian neighbours, had gradually converted her allies in the islands and on the coasts of Asia Minor and Thrace into dependent subjects and tributaries. But Athens had not, like Rome, the prudence to combine these scattered members of her empire, elements of discord and trouble as much as of strength to the sovereign state, by the free communication of the rights of citizenship. Nor indeed could this wise expedient have availed in the case of Athens as in that of Rome. For the states over which the empire of Athens extended were either independent governments reluctantly submitting to her yoke, or the weak dependencies of a rival power, and indisposed to acknowledge the sovereignty of Athens but so long as that power wanted the vigour and the enterprize to head a coalition against the common oppressor. There were thus in the very constitution of the Athenian empire, materials of jealousy and disunion, which no line of conduct but the impolitic one of surrendering an arbitrary rule into the hands of the people who had groaned under it, could long have kept from explosion. And, in fact, it was not the policy of Athens (masterly as that policy was under the hands of her great leaders) which sustained her empire for more than fifty years, so much as the inertness of her great rival, Lacedemon, and the difficulty of bringing the several grievances of the subject-states to bear on some decisive point, capable of influencing the movement of the whole in a strenuous concerted effort of resistance. At length we see this effort in the outbreak of the Peloponnesian war, as well as the difficulty of it in the complicated diplomacy by which that great movement was preceded, and in the reluctance of Lacedemon to bring home to herself the necessity of exertion.

But, whilst Athens was thus aggrandizing herself against a day of retribution from the insulted states of Greece, she enjoyed the sunshine of her day of empire, in the brilliant assemblage, which she then witnessed within her walls, of the great, and the learned, and the eloquent, from all parts of Greece.[1] While her arms and her enterprize were setting foot on every sea and land, her attractiveness as a home of genius and civilization, was evidenced in the number of strangers frequenting her porticoes, and groves, and theatres, and temples, and the houses of her nobles. During thirty years of this period of glory, the philosopher Anaxagoras was employed in propagating there the doctrines of the Ionic school, honoured by the patronage of her great men, and the revered master of her choicest spirits in the newly-acquired taste for philosophical inquiry. During, also, a considerable portion of the same period, the sophist Prodicus was domesticated within her walls, surrounded by crowds of admiring pupils from the highest ranks of her citizens, eagerly catching the inspiration of that rhetorical ability for which he was famed. Occasionally, too, amongst the distinguished visitors of the city, might be seen other illustrious professors of the day, also familiarly known by the name of sophists, then a complimentary designation,—Protagoras of Abdera, Gorgias of Leontium, Hippias of Elis,—drawn there by the demand for that literary merchandize, of which they claimed the monopoly. There also were now collected, as in a school of all arts, the great masters of the drama, of sculpture, and painting, and music, and the gymnastic exercises. So that Athens, at this time, contained within her own bosom abundant resources for the enlargement of the mind, whether in the eminent men who formed her society, in the lectures and conversation of the professors of science, or in noble works, the specimens and examples of what genius could effect. Athens contained, also, doubtless, much to enervate and corrupt the moral judgment, whilst she presented every thing to exalt the imagination and refine the taste. Her political institutions, well-balanced as they had been left by Solon, were now violently disturbed. In the course of these years of imperial greatness and prosperity, they received a large infusion of that licentious spirit, which the naval successes of the Athenians had engendered in the lower order of the citizens,[2] and the flattery of successive demagogues had fostered and diffused through the whole of the state. Now, also, faction divided the ties of family and kindred, and formed associations of the people for every lawless purpose of private ambition and cupidity. Their highest and purest court,—one principal anchor of the state, according to the intention of their great legislator,[3]—the Areopagus, was mutilated in its powers. And whilst numerous courts of law, thronged by their hundreds of judges, chosen by lot from the whole body of citizens, were constantly open,[4] and an idle populace were encouraged, by pay from the public treasury, to attend on the business of these courts, the functions of the legislative and deliberative bodies were virtually suspended. The peremptory power of these judicial committees, in which the people at large felt and exercised a despotic authority, became the real executive of the state. Then came into intense activity the vile system of sycophancy,—a system, under which the life and property of the wealthy were at the mercy of every needy adventurer who could speak to the passions of the people, and earn a livelihood for himself by a career of successful prosecutions.

Nor was public corruption unattended by its usual evils of private luxury and debauchery. At this time too, there might be observed in the heart of a city which prided itself on its pious feeling,[5] and amidst the frequency and splendour of festivals and external rituals of religion,[6] a profane scepticism with regard to the fundamental principles of religion and morality. A spirit of self-conceit and of presumption of knowledge, already natural to the Athenians, had now widely spread among the people; and every one was by turns dogmatist or sceptic,—according as it was his own opinion that he asserted,—or as he might display his ingenuity in questioning some received principle, or disputing some opinion proposed by another.

Add to these circumstances, the effect of a large slave population, the degraded ministers to the wants and the wealth of an insolent body of citizens, and of a number of resident foreigners engaged in carrying on the manufactures and trade of the city, paying a tax for their protection, and contributing to the military strength of the state, though excluded from its franchise. The slave, indeed, and the foreigner, lived more happily at Athens than at Lacedemon, or perhaps any other city of Greece, especially during a time of war, when their services were needful to the state.[1] Slavery, therefore, acted probably less injuriously on the character of the Athenian master, than it did elsewhere in Greece. It was tempered by the social humour of the people. But the facility thus afforded to the citizens of living in indolence and ease, and abandoning all domestic employment for the excitement of the public assemblies, and the courts, and the spectacles, naturally induced a neglect of the private and domestic duties. There is reason to believe, that whilst the Athenians appeared in the face of the world the most light-hearted of men, they were secretly unhappy in their homes; living in listlessness from day to day on the alms of their public pay; many of them reduced from affluence to poverty through the loss of lands and property by the ravages and pressure of war, and yet unable or unwilling to use the necessary exertions to relieve themselves from their distress. It is evidently no singular instance which Xenophon has given of this state of things at Athens, when he tells us of Aristarchus complaining to Socrates of the number of poor female relatives who, from losses in the course of the Peloponnesian war, were thrown on him for support. The difficulty which Aristarchus felt, was, that he could not expect persons who were free-born and his own kindred, to undertake any manual labour, so as to assist in maintaining themselves. Happily, however, he adopts the friendly suggestion of Socrates, and makes the experiment of setting them actively to work. The experiment succeeds; and thus contentment and cheerfulness are introduced to a home where before all was gloom and mutual suspicion.[2]

[6] Xenophon, in his *Memorabilia*, i. c. 4, gives an instance in Aristodemus of one who not only had a contempt for all religion, but even derided those who concerned themselves with it.

In the meantime, a great number of mechanics and tradesmen had risen to wealth and importance, in consequence of the demand for every species of labour and trade, resulting from the multiplied population of the city and its numerous foreign dependencies and connexions, and, in particular, from the magnificent public works carried on during the administration of Pericles. All this while, Athens was becoming more and more a mercantile community, in the midst of strong aristocratic prejudices, still surviving, and rendered, indeed, more intense by the opposition growing up around them. In many instances, the older families would be declining in wealth, exhausted by the burthens of the state or the extravagance of individual expenditure; whilst new families, the creations of successful trade and enterprize, would be obtaining influence by the force of their wealth, and encroaching on the privileged ground hitherto occupied only by right of birth. It may be easily conceived, therefore, that the mass of the society of the city would be now all fermentation and restlessness; the one class pushing their interests and their claims to equality founded on their personal title, whilst the other obstinately clung to the exclusiveness and the pride of hereditary right.

But we shall best judge of the distempered state of the social atmosphere of Athens, by adverting to the character of female society as it existed there. It has often been remarked, as the glory of modern and Christian civilization, that it has restored woman to her due place in the scale of social importance, and thus most effectually chastened and elevated the general intercourse of human life. In a country so essentially social as Greece, and especially at Athens, it was practically impossible to impose on the women the absolute seclusion of eastern despotism. Still it was even at Athens considered the rule of propriety, that the wives and daughters of citizens should live in the strict privacy of their homes, and be known and noticed as little as possible among the other sex, even for their virtues.[3] But whilst the virtuous matron was excluded from the social circles, the place which she should have held in Athenian society was filled by other females, strangers to family ties, and attracted to Athens by the licentiousness and wealth of an imperial city. The union of high intellectual endowments, and a masculine dignity of understanding, in some distinguished individuals of this class, with the graces of female loveliness, appealed with a powerful interest to the sensual elegance of Grecian taste. We find, accordingly, at Athens, at this time, forming, as it were, the female court of the sovereign people, the Milesian Aspasia, and others of less name, living in the profession of a scandalous course of life, not only without shame, but even in the enjoyment of public respect. It was not the general of the commonwealth only that felt the spell of the charms of Aspasia, but grave philosophers resorted to her house; and even the ladies of private families, in violation of the restrictions of custom, were taken there by their friends; all eager to hear those interesting conversations, and lectures in political and rhetorical science for which she was famed.[4] We may judge how deeply corrupted must have been the standard of public opinion in Greece, when female profligacy could thus veil itself from the eye of moral observation, under the graces of splendid accomplishments of mind and person. So thoroughly had refinement of intellectual taste and of manners, together with the grossest impurity of morals, pervaded the whole society of Athens, that even those who were elevated above the world around them in talents, and strength of character, and kindliness of disposition, as Socrates was, imbibed in some measure the poison of the infected atmosphere which they breathed.

Such, then, was that state of things in which Socrates was trained, and which will greatly account to us for that peculiar form which the character of his philosophical teaching exhibits. For he was ever an Athenian instructing Athenians. He spoke as one fully conversant with the habits of thought and action of his countrymen; as knowing what kind of instruction they most needed, and by what mode of address he might best win their attention. We might expect, therefore, to see in him some leading traits of the Athenian civilization of his time; a teaching, admirable indeed in its main features, but bearing, at the same time, some marks of that corrupt state of society which called it forth, and to which it was immediately addressed.

The son of Sophroniscus a sculptor, and Phænareté a midwife, and himself brought up in his father's art, he yet enjoyed those advantages of mental culture and social refinement which were common to every citizen of the democratic Athens. The meanness of his birth and his poverty, much as high birth and wealth were esteemed there, would not exclude him from familiar intercourse with persons of the highest rank and consideration in the state. Nor, indeed, could the advantages of education be restricted to a privileged few, where every one lived in public, and where knowledge was for the most part acquired and communicated by conversation and oral discussion.

If, in the general relaxation of discipline at Athens, the citizen was no longer obliged to submit himself to a prescribed course of education under the eye of the state, and it was left to each person to avail himself, or not, of the sources of instruction presented in the intellectual society of the city, Socrates was not a person to neglect the advantages placed in his way. Money he had not, to pay to the Sophists, the great masters of his day. But he had from childhood an inquisitive mind. He felt that he was thrown on his own resources of thought, and that he must be his own master in the art of education. And to this great object he appears to have bent, from the earliest time, all the powers of his energetic mind. making it his constant employment to inquire from every one,[1] and collect on every occasion, some hint towards the right prosecution of it. We may picture to ourselves the young Socrates, resembling the Socrates of mature life, freely entering into conversation with all to whom he had access; feeling and acknowledging his own ignorance; listening attentively to all that he heard; weighing and discussing it in his own mind with patience and acuteness; and not resting until he had traced it out in all its bearings to the utmost of his power. Thus would he gradually form and strengthen that faculty of observation, and that analytical acumen for which he was afterwards so eminently distinguished.

Nor has Plato improbably put a prophecy of his future eminence in the mouth of one of the great masters of the day, when he makes Protagoras say of him, with the self-complacency of the man of established reputation: "For my part, Socrates, I commend your spirit, and the method of your reasoning; for whilst in other points I am no bad sort of person, as I think, I am the farthest from being an envious one. For concerning you in particular, I have already observed to many, that of all I meet, I admire you by far the most; of those of your own age, even to the extreme; and I say too, I should not be astonished if you were to turn out a man of celebrity for philosophy."[2] To the same effect is the story, that his father, being at a loss how to educate him, consulted the Delphic oracle, and was advised to leave him entirely to his own bent, inasmuch as he had a director in himself superior to a thousand teachers.[3] The simple interpretation of what is here thrown into the form of marvel probably is, that he gave, even when a child, striking indications of a devotedness to those studies which became the business of his manhood.

The notice of a wealthy individual of Athens, the excellent Crito, appears to have been early attracted to Socrates. Crito was of about the same age as Socrates;[4] and an attachment to the pursuit of philosophy, and an admiration of the character of Socrates, naturally led to that intimacy which he now commenced with the young philosopher, and steadily maintained through his subsequent life. Through him Socrates was relieved from the necessity of earning his livelihood by the profession of a sculptor; or, as Laertius expresses it, "was raised from the workshop."[5] Sculpture, indeed, was in high honour at Athens, especially at this time. For Phidias, enjoying the protection of Pericles, was now adorning the city with the immortal productions of his own chisel, as well as other noble works of art executed under his taste and direction. But to follow up the profession with success, required a devotion of mind and hand that must preclude the opportunities indispensable for the moral student. And though, for a time, Socrates worked at the art,—and with success, if a statue of the Graces in the citadel of Athens, attributed to him, were really his workmanship;[6]—we may imagine how distasteful the occupation, however intellectual in itself, must have been to a mind, so eager for observation on living man, so intent on mental and moral phenomena, as that of Socrates; and how gladly he would exchange the labour of his paternal art for that philosophic leisure which the friendship of Crito held out to him.

The world of that day reproached the philosophers with servility, taunting them with being ever seen at the "gates of the rich." In some instances, the reproach may have been just. But in general, the fact was the reverse. Their society rather was courted by the great and wealthy, who were proud of the reputation of being patrons of philosophy. To Socrates, indeed, the patronage of a man of wealth would be peculiarly acceptable, not so much for the means of subsistence, about which he was absolutely thoughtless and indifferent, as for the society itself to which he would thus be introduced, and the opportunity of carrying on his researches into philosophy, both by books and by the oral instructions of its living professors. To him it would be the very means by which he would enlarge his field of moral observation. The social evenings of Athens were the natural sequences of the mornings of the agora, and the courts, and the council, and the assembly. They prolonged in festive conversation that strife of words and competition of argument, which had been begun in the busy and serious discussions of the morning, and of which the last murmurs had scarcely died away on the ear of the assembled guests. For Athenian life was a life of constant excitement. What Demosthenes observed an hundred years afterwards, and an apostle four hundred years later still,—that the Athenians did nothing but go about and ask the news of the day,—was a characteristic of the people already strongly developed at this period of their history. Socrates, who, in his own person, gave a philosophical cast to this inquisitive spirit, would be peculiarly interested by such opportunities of exercising it as were presented in the animated encounters of the symposium. There he would see human nature displayed in some of its most striking forms. There he would meet the citizen full of years and honours, experienced in the arts of government and diplomacy, and in the service of the state by land and sea; the poet flushed with his victories in the dramatic contest; the sophist armed at all points for the display; the philosopher expounding his theories; the orator, the idol of the people in his day; the courtly patron of literature; and a circle of young men, the flower of the highest rank in the state; each bearing his part in the free and lively interchange of thought, emulously provoking one another to discussion, and contending for the mastery in the conflict of debate.

By such society Socrates would be effectually prepared for that active enterprize of philosophy, which formed the whole engagement of his life. In the meagre information handed down to us respecting the details of his history, we are not able to ascertain at what precise period of life he began his career of public teaching, or at least attracted notice as the philosopher of Athens. The transition would probably be gradual, from the youthful inquirer, to the mature and expert teacher of others. This transition would be the less perceptible in the case of Socrates, from the circumstance, that he never professed to *teach*, even when he was most actively employed in teaching; but still, at the last, as he had done from the first, merely to *inquire*.[7] For his part, he disdained the *profession* of philosophy. He was disgusted with the vain pretension advanced by the Sophists, of being masters of every science, and capable of imparting instruction on any given subject. He accordingly set out with the antagonist position, that he *knew nothing:* that his only wisdom, if he possessed any beyond other men, consisted in his being *aware* of his real ignorance, whilst others ignorantly presumed on the possession of a knowledge which they had not. His teaching, therefore, was only a continuation of the process of educa-

tion of his own mind, by extending it to the minds of others. He was fond of describing it as an *examination* or *scrutiny* of the mind; a method of finding out the real condition of each mind, and so of preparing it for the due exercise of its powers in the practical emergencies of human life. He saw that the evils of life arose, in great part, from the wrong judgments of men,—from their mistaking their own powers, presuming on their knowledge, and ability, and the truth of opinions adopted without inquiry. He endeavoured then to effect the cure of human error and unhappiness by a reformation of the intellect. The first step towards this would be taken, if men could be only divested of this vain self-confidence; if they could be brought to *suspect* that they might be mistaken in their judgments, and so to *question* themselves. This preliminary labour was employment enough for any one man's life, especially in a society such as that of Athens, so entirely infected with the sophistical leaven. Socrates wisely confined his exertions to this simple object. He is content to excite inquiry,—to provoke discussion,—and thus to suggest the necessity of self-discipline in order to right judgment. He does not, like other philosophers, quit the seclusion of a study, or the field of foreign travel, to come forth to the world the accomplished teacher of the accumulated wisdom of years of solitary thought and reflection. Whilst philosophizing in the agora and the streets of Athens, in the workshops of the artizan, or at the banquets of the rich, he is still employed in the work of *disciplining* the mind. Thus he passes on insensibly from the education of himself to the education of others, and it is difficult consequently, or rather impossible, to say in his case, where the character of the learner ends, or where that of the philosopher and teacher begins.

Yet, entirely as Socrates disregarded all positive knowledge, and threw himself on the resources of a shrewd and extensive observation of human nature, we must not suppose that he neglected to inform himself in the existing systems of philosophy, and the particular sciences as they were then understood and taught. There is reason to believe, that he had accurately studied the systems of the early physical philosophers of the Ionic school, as well as the moral and mathematical theories of the Pythagoreans, and the dialectics of the school of Elea. Without supposing him so deeply versed in the doctrines of the several schools, as would be inferred from his exact discussions in the dialogues of Plato, there is still ample evidence, from the more direct account of Xenophon, that he was by no means ignorant of them. He had doubtless read much,[1] as well as observed much, when he commenced his philosophic mission. Xenophon indeed tells us that Socrates considered the physical and dialectical theories of his predecessors as unprofitable. But he takes care to add, that Socrates was not unacquainted with these theories. And in particular, as to the sciences of astronomy and geometry, he thought the attention of the student wasted in investigating their more abstruse theorems. But he was able (as Xenophon further observes), to speak on the subjects of these sciences also from his own knowledge of them.[2]

Nor are we to suppose that, whilst he had properly no master in that line of philosophical study which he had marked out for himself,[3] he had no aid in the cultivation of his mind, from the living masters of philosophy in his day. The long residence of Anaxagoras at Athens, probably coincides in time with part of the early life of Socrates.[4] To him, therefore, Socrates would naturally have access, as well as to Archelaus,[5] his disciple, and the inheritor of his doctrines. If he had no personal intercourse with Anaxagoras, it is at least highly probable, from the testimony of Plato, that he was acquainted with the famous treatise of Anaxagoras, which contained his theory of the universe.[6] And perhaps we may distinctly trace the early and abiding influence of the lessons of this great philosopher throughout the teaching of Socrates, in his uniform maintenance of the principle of an all-disposing mind, the glory of the system of Anaxagoras.

To the writings of Heraclitus, his attention appears to have been drawn by the poet Euripides; if the anecdote be true, as related by Laertius, that on being asked by Euripides, who had put them into his hand, what he thought of them, he replied, alluding to the studied obscurity of that philosopher; "What I understand is excellent; so also, I suppose, is what I do not understand; only there is need of some Delian diver to reach the sense."[7] He had also opportunities of conversing with Zeno the Eleatic, and Theodorus of Cyrene; the former eminent for his dialectical skill, the latter the most distinguished geometrician of the time. And though his scanty means precluded his attendance on the professional lectures of Prodicus, the fashionable teacher of rhetoric at that day at Athens, it cannot be doubted that he would on several occasions have been among the company assembled at the house of some wealthy citizen, and there heard from the lips of that accomplished master of language those elaborate oratorical displays which made his name proverbial for wisdom.[8] With the poet Euripides, indeed, the disciple of Anaxagoras and Prodicus, and who was his senior only by a few years, he appears to have lived in habits of intimacy. With Euripides he would probably often have discussed those ethical topics which the poet so greatly delighted to transfuse into his tragic scenes, and associate with the interest of dramatic incident. They were in fact brother-labourers in the same cause, though in different ways. For whilst Euripides endeavoured to work a reformation of his countrymen, by didactic addresses insinuated through their feelings, amidst the interest of tragic story, Socrates appealed at once to their understandings, and amidst the business or pastime of real life. The envy of contemporaries was prone to attribute the excellence of the poet in some of his dramatic efforts, to the aid of his philosopher-friend.[9] The truth probably is, that the benefit of their intercourse was mutual; that, whilst the poet's imagination was informed and chastened by the shrewd and severe wisdom of the philosopher, the philosopher also, ever intent on his calling, would enlarge his mind with riches drawn from the genius, and taste, and learning of the poet.

The co-existence of literary and philosophic elegance with the most disgusting coarseness of moral feeling and conduct, in the character of the Athenian courtesan, has been already noticed. To Aspasia, the heroine of her class, as we may call her, when we refer to her influence over Pericles, and the encomiums of her by Plato and others, Socrates is expressly stated to have been indebted for instruction in rhetoric, as also in other subjects.[1] Whilst Xenophon also introduces him familiarly conversing with Theodota, whom he describes as living in great splendour at Athens, the object of general admiration for her personal charms, and inviting her to become his disciple,[2]—Plato leads us to believe that Socrates was himself the disciple of another of the same class, the Mantinean Diotimè, who, among her other accomplishments, was distinguished in particular for her skill in the art of divination.[3]

[2] Xenoph. Mem. iv. 7.

[3] He reckons himself in Xenoph. Conviv. i. 5. among the αὐτουργὸι τῆς φιλοσοφιάς.

[4] It must be admitted, however, that the chronology of the life of Anaxagoras is very doubtful.

[5] Archelaus is called both a Milesian and an Athenian. The probability is that he was a Milesian, since philosophy had scarcely yet found a home at Athens.

[6] See the Phædo, p. 97. The writings of Anaxagoras appear to have been extensively circulated. Socrates is made in Plato's *Apology* to say to Melitus, ὄιει αὐτοὺς ἀπειρους γραμμάτων εἶναι, ὥστε ὀυκ ἐιδέναι ὅτι τ᾽ Ἀναξαγόρου βιβλία τοῦ Κλαζομενίου γέμει τουτων τῶν λόγων.

[9] Aristoph. Nub. Diog. Laert. in vit. ii. 5.

Instruction in music formed an important part of Athenian education. Socrates, it seems, did not neglect the opportunities which the presence of the great masters of the art in Athens afforded him of learning its principles. Connus accordingly is claimed for him, as his master in music.[4] Damon, another celebrated musician, though not more eminent in the science which he professed, than as a politician and sophist, was resident at Athens during part of the administration of Pericles, the intimate and counsellor of that great statesman, as well as his instructor in music.[5] From him also, we are told, Socrates received instruction in the art. By these accounts, however, we may probably understand, not that he became a proficient in the musical art, but that he had listened to Damon as well as to Connus, discoursing on the subject, and studied its theories under them, so far, at least, as music entered into the general pursuit of philosophy.[6]

It should be observed, indeed, that though Socrates strongly discouraged the *presumption* of knowledge in all with whom he conversed, he did not disapprove of the acquisition of particular kinds of knowledge. He communicated whatever he knew to every one that came in his way; and where he was himself unacquainted with any subject, he referred his hearers to those who possessed the information.[7] He was not in fact opposed to knowledge in itself. He was glad to embrace it wherever it could be found. But he was an enemy to the substitution of mere intellectual acquisitions,—and those often superficial and unreal,—for *education* of the mind and character. He felt, and justly felt, that knowledge by itself was vanity. The tendency of the age was to ascribe value exclusively to mental acuteness and dexterity. Ingenuity and cleverness obtained the merit and the prize of wisdom. His labour was to draw his countrymen from thinking too highly of their boasted knowledge. He wished them to see how greatly they overrated intellectual acquirements,—how much they had yet to learn if they would be real proficients in wisdom.

Socrates indeed appears to have regarded philosophy in the light of a sacred mission, to which he was specially called, rather than of a study and exercise of the mind. This notion of philosophy had already been exemplified by Pythagoras and his followers. But they had realized it by forming themselves into distinct communities or colleges; separating themselves from the world around, by a solemn initiation, and the practice of an ascetic discipline. Socrates, however, had no thought of changing the outward form of society. He did not propose, like Pythagoras, to institute a refuge from the pollutions and misery of the world, or to educate a peculiar brotherhood, who should afterwards act on the social mass. He did not address himself to the few. His school was all Athens. or rather indeed all Greece. Leaving society as it was, he sought to infuse a new spirit into it, by carrying his philosophy into every department of it. He therefore went about among all classes of people, preferring none, despising none, but adapting his instructions to every variety of condition and character. Thus did he in truth, according to the observation commonly applied to him from the time of Cicero, bring down philosophy from heaven to earth; but not so much by being the first to give a moral tone to philosophy, as by the universality and philanthropy of his teaching. Philosophy in his hands was no longer an exclusive and privileged profession. It no longer spoke as from an oracular shrine, and in the language of mystery. It now conversed with every man at his own home,—submitted to be familiarly approached and viewed without reserve,—and, instead of waiting to be formally consulted by its votaries only, volunteered to mingle in the business, and interests, and pleasures of every-day life.

His manner of life and of teaching is thus described by Xenophon.[8]

"He was constantly in public. For early in the morning he would go to the walks and the gymnasia; and when the agora was full, he was to be seen there; and constantly during the remainder of the day, he would be wherever he was likely to meet with the most persons; and for the most part he would talk, and all that would might hear him."

The nature of his conversations is thus further reported by the same faithful authority:

"No one ever saw Socrates doing, or heard him saying, any thing impious or profane. For not only did he not discourse about the nature of all things, as most others, inquiring how, what by the sophists is called the universe, consists, and by what laws each heavenly thing is produced; but he would point out the folly of those who studied such matters. And the first inquiry he would make of them was, whether they proceeded to such studies from thinking themselves already sufficiently acquainted with human things; or whether they thought they were acting becomingly in passing by human things, and giving their attention to divine. He would wonder, too, it was not evident to them, that it was not possible for men to find out these matters; since even those who most prided themselves on discoursing of them, did not agree in opinion with each other, but were affected like madmen in relation to one another. For of madmen, whilst some did not fear even the fearful, others were terrified at things not terrible; whilst some were not ashamed to say or do any thing even before the multitude, others objected even to going out into the world; whilst some paid no honour to sacred things, or altars, or any other religious object, others worshipped even stones, and common stocks, and brutes. So of those who speculated on the nature of the universe, whilst some thought that Being was one only, others thought it was infinite in number; whilst some thought that all things were in perpetual motion, others thought it impossible for any thing to be moved; whilst some thought that all things were in a course of generation and destruction, others thought that nothing could possibly be generated or destroyed. He would further consider respecting them thus: whether, as the learners of human things think they shall be able to make practical use of their knowledge for themselves and any one else at pleasure, so also the searchers into divine things hold, that having ascertained by what laws each thing is generated, they shall be able to produce at pleasure winds, and waters, and seasons, and whatever else of the kind they may want; or whether they have no such expectation, but it suffices them only to know how every thing of this kind is generated. Such, then, was his manner of speaking about those who busied themselves with these matters. But, for his part, he was ever discoursing about human things, inquiring what was pious, what impious, what honourable, what base, what just, what unjust, what sobriety, what madness, what courage, what cowardice, what a state, what a statesman, what a government of men, what the character of a governor; and about other subjects, which, by being known, would make men honourable and virtuous, whilst those who were ignorant of them, would justly be called slavish."

Xenophon has thus fully touched the character of the teaching of Socrates in its leading points, and the nature of his constant occupation at Athens. The intermissions of military service appear to have been the only occasions of any variation in this uniform course of life. No other country had any charms for him, as no other afforded such rich opportunities of conversing with men, and studying human nature.[1] His activity was essentially different from that either of his predecessors or successors in the path of philosophy. They travelled from place to place searching for knowledge, storing their minds with various observations, and making philosophy their formal business. Socrates, as he had no stated school or place of audience, so he had no design of framing any system of philosophy, or of enlarging the researches and discoveries of former philosophers, or of pursuing knowledge as an ultimate object. He regarded himself as called by the voice of Deity, to undertake the reformation of men, and especially of his fellow-citizens, as constituting his proper sphere of duty, from their corruptions of sentiment and conduct. He stood, therefore, by the great stream of human life which was ever flowing at Athens, and watched its course. He is said once to have visited Samos in company with Archelaus, the disciple of Anaxagoras, and also to have gone to the Pythian and the Isthmian games. With these exceptions, and those of the occasions of military service abroad, he appears to have constantly remained at home, unattracted from the town, the seat of his philosophic mission, by invitations even to the courts of princes. In vain did Scopas of Cranon, and Eurylochus of Larissa, offer him money, and invite him to visit them.[2] He could refuse also the hospitality of Archelaus, king of Macedonia, the same with whom the poet Euripides found a kind and honourable refuge in his old age, from the envy of his countrymen, and domestic grievance. His refusal of the invitation of Archelaus is said indeed to have been accompanied with the declaration of his feeling, that he could not brook the acceptance of a favour which it was entirely out of his power to return.[3] Nay, so entirely engrossed was he in the work to which he had devoted himself, that he was a stranger, as Plato represents him, even to the immediate neighbourhood of the city. The banks of the Ilyssus, even then classic ground, rich with legendary associations, could not seduce him from the agora and the crowd; so that he seemed scarcely at home beyond the walls of Athens.[4]

No Athenian, however, could decline the military service of the state. And this service, at the time of Socrates, often engaged the citizen in hazardous enterprizes and long absences far from his home. The first occasion on which Socrates is related to have served, was in the Chersonese at Potidæa, just before the opening of the Peloponnesian war. The service in which the Athenian soldiers were engaged here was one of great hardship. It was in the winter season, and the climate in those parts was most severe. Amongst those who distinguished themselves by their resoluteness and gallantry, none was so conspicuous as the philosopher. Whilst others were clothing themselves with additional garments, and wrapping their feet in wool, he was observed in his usual dress, and walking barefoot on the ice, with more ease than others with their shoes. Nor even amidst these circumstances, did he merge the character of the philosopher in that of the soldier. He was seen one morning at sun-rise fixed in contemplation. At noon he was in the same position, and still in the evening, and so continued through the night, until the sun-rise of the following day. Such, too, was his bravery in the engagements at Potidæa, that he earned for himself the prize of distinction, but readily sacrificed his claim to the wishes of the generals, in favour of a more illustrious candidate in the person of Alcibiades. Alcibiades himself would have refused the honour as due rather to Socrates; for to the unwillingness of Socrates to leave him wounded on the field, he had been even indebted for his own life, and the preservation of his arms, after the battle. But the philosopher, with a true magnanimity, insisted on the award of the generals.[5]

The next occasion of military service, in which he was scarcely less distinguished than at Potidæa, was in the eighth year of the Peloponnesian war, at the battle of Delium in Bœotia. The battle was an unsuccessful one to the Athenians, and they were forced to retreat in disorder. Alcibiades was also present on this occasion, and overtook Socrates in company with Laches, one of the generals, on the way. He was on horseback, and comparatively therefore out of danger, whilst they were on foot. He had opportunity, therefore, of admiring the presence of mind which Socrates displayed on the occasion, even beyond Laches, and the steadiness and vigilance with which he kept the enemy from pressing upon them, and so secured their retreat.[6]

These incidents seem to rest on indisputable evidence. The account of them is put into the mouth of Alcibiades by Plato, in that most ingenious of his dialogues, the *Banquet*. The very form in which they are introduced, related as they are by an eye-witness, and that witness Alcibiades, the person, next to Socrates himself, most interested in them, may justly be regarded as giving a sanction to their history, independent of the fictitious circumstances of the dialogue.

The third occasion on which Socrates served as a soldier was again in Thrace, at Amphipolis,[1] in the same year as that of the unfortunate expedition to Delium. No particulars are mentioned of this adventure. But the fact itself is sufficiently attested. Nor, though it follows immediately on the affair of Delium, is it improbable on that account. For at this busy period of the war, when the Athenians were making demonstrations of their power, by the presence of their forces in different places at once, and when Brasidas was pushing his successes against them in Thrace, no individual of the military age, (and Socrates was not more than forty-six or forty-seven years of age at this time), would enjoy any long interval of relaxation from foreign service.

[5] Plato, Conviv. 220, a. p. 266; also Charmides.

[6] Plato, Conviv. p. 270. The story is again alluded to by Plato, in the dialogue, *Laches*. Laches is made to say that he had had experience of the *actions* of Socrates, and reminds Socrates of the day of their common danger, ᾗ μετ᾽ ἐμόυ συνδιεκινδύνευσας, κ. τ. λ. P. 182. Laertius says that Socrates saved Xenophon, who had fallen from his horse in the battle of Delium, (in vit. Soc. ii. 5–7.) But this cannot be true, as Xenophon would be much too young at that time for military service. In the Deipnosophists of Athenæus, (v. 55), doubt is thrown on these accounts of the military service of Socrates, and instances are given of the historical inaccuracy of Plato. The objections, however, as there given, are evidently thrown out in the wav of discussion, and not with perfect seriousness, as if the speaker really thought them of weight.

With these exceptions, Socrates appears then to have constantly resided at Athens. All this time, throughout his whole life indeed, he lived in great poverty, content with the least that might suffice for mere sustenance and clothing from day to day.

Yet it was no artificial, and melancholy, and fanatical life that he led. He accustomed himself to a strict moderation, not with any view to the mortification of the body, or as thinking that abstinence was in itself a virtue, but in order to self-command; by rendering himself as independent as possible of the circumstances of the body, to disencumber the soul of every burthen and obstruction to its free operation. There was nothing, indeed, of austerity in his life or manner. He might be seen walking barefoot, but it was not for the pain that it might inflict. It was only that he might bear cold and privations of every kind the better, and suffer the less inconvenience when exposed to necessary hardships, and require the less for his ordinary subsistence. So far was he from studying a discipline of bodily severity for its own sake, that he was observed at times mingling in the social festivities of his fellow-citizens with the full freedom of Athenian conviviality, and shewing that he could bear excesses which mastered others, without losing his self-command.[2]

One account, indeed, but not a very credible one, as it rests on the authority of Aristoxenus, an invidious writer, states that he was supported by the alms of friends, contributed from time to time for his relief. With his very limited wants, and his ready access to the house of Crito and other liberal patrons of philosophy at Athens, he would not have to depend on this precarious charity. The pittance which sufficed for the humblest citizen would suffice for him. He is said to have inherited a patrimony of seventy or eighty minæ.[3] But this sum, it is added, he lost (though the time is not stated when the loss occurred) by the failure of the person with whom it had been placed at interest. He possessed also a house in Athens; and he was able, however scantily, to support a family. So that we cannot suppose he was absolutely destitute of all resources of subsistence. He appears then rather to have voluntarily renounced every kind of worldly possession, so far as his own personal comfort was concerned, than to have been absolutely reduced to want by the pressure of circumstances. Poverty, in fact, was his profession, and not the mere necessity of his case. If he prided himself in any thing, it was in his avowal of his contempt for riches, and disregard of domestic interests and comforts, in contrast with the general habits of an age of selfish activity and profusion. The means of enriching himself, at least of extricating himself from want, were often placed in his power, and he as often rejected them. Alcibiades offered him land on which he might build a house, but he refused it pointedly, observing, "Had I wanted shoes, would you have offered me leather to make shoes for myself?—and ridiculous should I have been in taking it." Charmides would have given him slaves, as a source of revenue by their labour. This offer also he refused.[4] In the same spirit, he would often cast a look at the number of things that were sold, and say to himself, "Of how many things I have no need!"[5] Thus was his whole plan of life studiously opposed to the acceptance of any provision for his comfort or ease. It was a service of the Deity in which he felt himself engaged, and in the prosecution of that, solemnly devoted to a course of hardy poverty.[6]

In the domestic relations of life, he lived an Athenian among Athenians. He differed from other heads of families at Athens in this respect, that in his dedication of himself to his philosophic mission, he took no thought about the management of his private affairs. His home was abroad; his household the people of Athens. Still he discharged the duties of a husband, and the father of a family; and that under trying circumstances, unless the proverbial severity of temper of his wife Xanthippe be esteemed an idle scandal of the day. No Athenian, indeed, was truly domestic, in the sense of making his home the scene of his highest interest and enjoyment. Nor was Socrates domestic in this sense. Still less was he so than other Athenians; inasmuch as his very profession of life was a call from the bosom of his family. But in the midst of these avocations from his immediate home, and the vexations to which he was subjected there, he was not estranged from the ties of domestic affection. Xenophon has recorded a simple and touching trait of the character of Socrates under this particular point of view—a trait the more interesting, as almost every thing else that we know of the philosopher is drawn from his life in public. It occurs in the course of a conversation between Socrates and his son Lamprocles, who had complained of the insufferable temper of his mother Xanthippe. "What," said he to the youth, "do you think it more annoying to you to hear what she says, than it is to the actors, when in the tragedies they say every thing bad of one another?" "But they, I conceive," replied the son, "bear it easily, because they do not suppose that the speaker, in contradicting them, intends to hurt them, or that, in threatening, he intends to do them any ill." "Then are you," resumed Socrates, "vexed, when you well know that what your mother says to you, she says, not only intending no evil, but even wishing more good to you than to any one else; or do you regard your mother as unkindly affected towards you?" Lamprocles disclaiming this latter supposition; "Do you, then," he added, "say of her, who is both kind to you, and takes every possible care of you when you are sick, that you may recover, and want nothing proper for you, and who, moreover, prays to the gods in your behalf for many a good, and pays vows,—that she is vexatious? For my part, I think, if you cannot bear such a mother, you cannot bear what is good for you."[7]

From the description given by Plato of the family of Socrates in the prison-scene, it would appear, that Socrates had other three children besides Lamprocles,—for Lamprocles died at an early age, before his father,[1]—who were yet children, one of them a boy, another a child in the arms, at the time of their father's death.[2] We learn from other authorities,[3] that two of his children were named Sophroniscus and Menexenus; but they are said to have been the children, not of Xanthippe, but of another wife, Myrto, the grand-daughter of Aristides the just.[4] To account for this, it has been stated, that after their disasters in Sicily, the Athenians made a decree authorizing double marriages, with the view of recruiting their exhausted population. But this statement does not appear to be borne out by the earlier authorities on the subject of Athenian legislation. Nor is it probable that a law should have been enacted, directly sanctioning a form of polygamy. It appears, that during the pressure and confusion of the Peloponnesian war, persons obtained the freedom of the city of Athens, whose title was objectionable on the constitutional ground of their not being born of citizen-parents on both sides. Thus had Pericles, after the death of his two legitimate sons, obtained the admission of his son, Pericles, by Aspasia, to the privilege of citizenship;[5] though he had himself carried, some time before, a law of strict limitation, under which, nearly four thousand were deprived of the franchise.[6] Such extension of the privilege to the offspring of illegal unions, possibly gave a pretext to the supposition, that a decree passed at Athens sanctioning bigamy.

[3] About L.400 of our money. Plutarch (in his life of Aristides) finds fault with Demetrius Phalereus for having endeavoured to remove the imputation of poverty from Socrates, by stating that Socrates had land of his own and seventy minæ put out to interest by Crito. Demetrius, however, seems only to have stated what he believed to be the truth. The idea of his extreme indigence originated probably with the caricatures of his profession of poverty by the comic poets; and true as it was substantially, was afterwards, it seems, maintained by his friends and admirers, as the evidence of the consistency of his life with his avowed contempt for worldly possessions.

[7] Xenoph. Mem. ii. 2.

Some difficulty, however, arises on the subject of the marriage of Socrates, from the conflict of authorities. Whilst it is asserted on the one hand, that he was married to Myrto and Xanthippe at the same time; on the other hand, others assign them both as his wives, but in succession, and also differ as to the order of succession. But the silence of Plato and Xenophon respecting any other wife of Socrates but Xanthippe, and their coincidence in speaking of her only as the mother of his children, may be regarded as sufficiently decisive of the point against every subsequent authority. Indeed, the reference to Aristotle, given by Laertius, which is the chief ground for believing that Socrates was married also to Myrto, is very questionable. Plutarch doubts whether the treatise to which Laertius appeals for the fact, is the genuine work of Aristotle. From the manner, too, in which the name of Myrto appears to have been introduced in the account, nothing more may have been intended, than that Socrates found her in a state of widowhood and distress from poverty, and took care of her at his own home.[7] Aristides belonged to the same tribe and the same demus or borough, as Socrates; and a reverence for the virtues of the grandfather, may have combined with these almost domestic ties, to call forth such an act of friendliness to the disconsolate Myrto. And, if this be the case, as is probable, it would only add an interesting instance of that liberal benevolence which characterized the whole conduct of Socrates.[8]

It is a confirmation of this conclusion, that all the anecdotes of the private life of Socrates, with one exception, and that evidently a fabricated instance,[9] bring Xanthippe on the scene. On his inviting some wealthy persons to supper, it is Xanthippe who is distressed by their deficient means of hospitality, and to whom he replies, "Take courage; if they are worthy people, they will be satisfied; if they are worthless, we shall care nothing about them."[10] It is Xanthippe whom he reproves for her particularity about her dress on the occasion of some public spectacle, as more desirous of "being seen than to see."[11] It is of her again that Alcibiades expressed his wonder how he could bear with her, when he simply, but pointedly referred him to her just claims on his affection as the mother of his children.[12] On another occasion, his disciple, Antisthenes, is said to have asked him, with reference to Xanthippe, why he did not study to improve the disposition of his wife, whose violence of temper (he observed) was unexampled in the history of domestic life. Instead of confirming the censorious remark, he turned it, according to his usual method, to a practical illustration of his philosophy. "If Xanthippe was hard to be controlled," was the tenour of his answer, "it was only a proper discipline to him for the management of men; as those who would be masters in horsemanship, began with managing the most spirited horse, after which, every other would be tractable."[13] These stories, and the like, handed down or invented by the humour of the times, may be merely exaggerations of the fact of the inconvenience and dissatisfaction occasionally felt at the philosopher's home, by his habitual neglect of his domestic concerns, and the duty of exertion consequently imposed on Xanthippe beyond Athenian women in general. She appears indeed to have tenderly loved her husband, if Plato has faithfully traced the picture of her visit to his prison, and her extreme anguish at that trying hour. And he also knew her value, if his affection may be judged of, as surely it may, by the kind and gentle considerateness of his manner in committing her to the care of his friends at parting, and his absolute reserve of his feelings on that occasion.[14] The picture indeed is drawn by the hand of a consummate master; and Plato, it is true, was not present on the occasion. But we must believe, that in painting a scene that must have been impressed on the mind of the disciples of the philosopher, above every other incident of his life, and of which persons then living must have retained a lively recollection, he took his outlines at least of these interesting particulars from the real state of the case.

But the allusion to these circumstances brings us prematurely to the solemn tragedy which closed his intrepid and energetic career. We have yet to contemplate him pursuing for many a year his unwearied labour of awakening his countrymen from their dreams of knowledge and happiness to the realities of their condition in the world. Great indeed must have been the address, which could recommend the severe and wholesome truths inculcated by him, to the hearing of the vain and volatile Athenians. To none is the practical application of a principle, so condemnatory of human folly and impertinence, as the maxim, "know thyself," truly welcome. And yet this was the burthen of the teaching of Socrates for a series of years, among a people, whom it was far easier to please by praising to excess, than not to displease by censuring ever so slightly. They would listen, indeed, patiently to general invectives on their public conduct, conveyed in the impassioned eloquence of their orators; as persons will even now sympathize with general descriptions of the depravity of human nature, or of whole classes of men. But all refuse the pain of direct self-application of the truth; and Athenians, especially, regarded with invidiousness every attempt to impart to them moral instruction. Every Athenian, they thought, was capable of communicating this kind of knowledge, at least every educated Athenian, every individual of the higher order of citizens.[1] They wanted no one to teach them virtue. Hence the allusion made on so many occasions by Socrates to the question, whether virtue could be taught or not. It was, indeed, part of the profession of the Sophists to teach virtue;[2] but it was as an accomplishment or art, and not as a *discipline of life*, that it entered into the system of the Sophists. Socrates uprooted this vain notion. He laboured to impress on the Athenians, that so far from their being able to teach virtue, there were none who knew what virtue was. They had yet to learn *themselves* in order to that purpose. This, then, was his great difficulty. It was not the difficulty of communicating *new* knowledge, but that of leading men to unlearn their presumptions and conceits, and to *feel the necessity* of moral instruction.[3] That he should have succeeded then in any degree in such an attempt,—that he should have been able to carry on the effort for so many years, in the very centre of Greek civilization,—that, proceeding on so broad and fundamental a principle of reformation, presenting no definite system on which a sect might fasten, no specific lure to the zeal of party, he should have drawn around him so many followers and admirers,—this is the extraordinary effect in the case of Socrates, which shows the powerful charm of his address. To persons offering any particular instruction, or professing to qualify them for the office of statesmen and orators, the Athenians were most ready to attend; and many doubtless did attend to the conversations of Socrates with this view. They could not but admire the skill which he displayed in arguing with every one that came in his way; not with the vulgar only, but with those who had the highest reputation for talent in reasoning, and for the extent of their knowledge. They saw his superiority to the Sophists, on the very ground on which the Sophists set up their pretensions. Many, accordingly, flocked to him as the best master in political science and dialectical skill, particularly as he was always accessible, and his instructions were perfectly gratuitous. Some, too, of a better nature than the rest, were won by the honest and manly purpose which shone through his teaching and manner on all occasions; whatever disguise of irony, or humour, or sophistry, he might assume. There were even some of the young men, whose habits of life were reproved, and principles condemned, by his searching interrogatories, but who yet were won to attention by the charm of his instruction, and patiently heard from him truths which they would not have listened to from any other lips. For who else could stay, even for a moment, the wild impetuosity of Alcibiades, or the ferocious arrogance of Critias? Their motives in resorting to Socrates were chiefly selfish and political. It was in pursuit of their schemes of ambition that they sought his society. Still he was able to retain them for a time at least, though they found his instructions very different from what they calculated on receiving; and so long as they continued to associate with him, they exercised a degree of self-restraint which strikingly contrasted with the habitual profligacy of their lives.[4] Alcibiades is represented by Plato, as confessing that he, to whom the feeling of shame was scarcely known, yet felt abashed before Socrates; that he was enchanted by him as by the flute of Marsyas, and constrained to acknowledge his own deficiences and neglect of private duty in the midst of his officious zeal for the public service. And this feeling, Alcibiades says, was general; for that there was no one, woman, or man, or boy, that could hear him, or even his words repeated by the most indifferent speaker, but felt taken by surprize, and riveted in attention.[5]

This attention, too, it should be observed, was excited by the address of Socrates, amidst much in his outward form and mien, that, by exciting ridicule, might have repelled the sentiment of respect. The comparison of him to the satyr Marsyas, with all allowance made for comic exaggeration, was true in more respects than that of the enchantment of his conversation. His countenance, strongly marked by that arch intelligence, which half-concealed, half-betrayed, the earnest deep thought, under the light veil of irony and humour, presented features resembling those of the grotesque images of the Sileni. There were the prominent dilated eyes, scarcely parted by the low ridge of the nose, the broad expanded nostrils, the wide mouth with its thick lips, such as the sculptors delighted to represent in those rude but poetic forms.[6] Then his manner of looking about him, his head fixed, whilst his eyes traversed the space around, glancing from side to side, excited the smile of wonder in the spectator, as to what this strange solemnity of aspect might portend. Add to this, the clumsy protuberance of his figure, so repugnant to Grecian notions of the symmetry of form, and the awkwardness of his movement[7] before the eyes of a people who had a lively perception of elegance in every gesture and motion.[8] These were circumstances which, to the fastidious taste of the Greeks, would appear more important than we, in these times, can well conceive. They judged of intellectual character more from physiognomy[9] (physiognomy, that is, considered as a science, of mental indications from bodily forms in general) than we are apt to do. Thus in regard to Socrates, the physiognomist, Zopyrus, who, as Cicero informs us,[10] professed to discern the manners and natures of men from their body and features, pronounced that Socrates was stupid and heavy, because the outline of his throat was not con-

cave, but full and obtuse. Prejudices accordingly drawn from the personal appearance of Socrates may reasonably be believed to have tended to render his teaching unwelcome in its first impressions. But soon this fastidiousness would give way as he proceeded; and those who began to listen with a smile at the uncouthness of his form, and the quaintness of his manner, would be attracted to admiration of the intelligent and kindly expression which lighted up those rude features, and would find themselves lingering in his presence in spite of themselves.

The story of Euthydemus "the handsome," as he was called, may be taken as a specimen of such an effect. Euthydemus, proud of his personal accomplishments, and not wishing to be thought indebted to any one for his learning and eloquence, had studiously avoided the society of Socrates. Socrates, however, with his usual dexterity, contrives to excite his attention, and gradually interests him in conversation. Euthydemus shrinks back at first on his self-conceit, but at length is so won upon by the persuasive reason of the philosopher, as freely to acknowledge his own ignorance and need of instruction; and, ever afterwards, he is found by the side of Socrates, his devoted admirer and follower.[1]

Some, indeed, took offence at the plain truths which Socrates brought home to them, and no longer frequented his society.[2] But these were the inferior sluggish minds, which no arts of address could rouse to a sense of their intellectual poverty. Generous, susceptible minds overcame their first reluctance, and yielded themselves fully to his guidance. The faithful attachment of many was evidenced, to the last moment of the philosoper's life. He might have commanded the use of Crito's wealth, had he desired it. Such, indeed, was the confidence which Crito reposed in his sincerity of purpose, and so highly did he value his instructions, that to no other would he commit the education of his sons, but made them fellow disciples with himself of his own revered master and friend. And this friendship was warmly requitted by Socrates. For it was by his counsel that Crito was saved from the malicious arts of the sycophants. These pests of Athenian society were not to be encountered by the simple testimony of a life contradicting their mercenary calumnies; and Crito was one of those who would rather pay their money, and compromise the attack, than take the trouble of defending themselves. They were only to be foiled by turning their own weapons against themselves. By the suggestion of Socrates, accordingly, Crito enlisted in his service a clever individual of this class, Archedemus, who effectually checked the iniquities of which his patron was the object, by counter-prosecutions of the sycophants, and exposure of their conduct; acting as a watch-dog, according to Xenophon's description, against those rapacious wolves.[3]

The devotedness of Plato and Xenophon to their master, speaks from every line of their writings. These writings are, in fact, as much monuments of the influence of Socrates over their minds, as of their own genius. And what human teacher has ever had such glorious trophies erected of the conquests of his philosophy as the extant works of these master minds? Entirely different as they are in character,—the one flowing with the full stream of impassioned feeling, and lively elegant imagination, and the abundant treasures of literary and traditionary wisdom,—the other sensible and acute and practical, forcible by his very simplicity and the terseness of his unaffected eloquence,—they bear distinct yet conspiring evidence of the ascendancy of that mind which could impart its own tone and character to such disciples. Both of them, indeed, lead us to think that they felt his society as a kind of spell on them. For, when Plato speaks of the charm of the discourses of the Sophists, he seems to speak in irony of them what he thought in truth of Socrates himself. So too, when Xenophon introduces Socrates describing himself as skilled in "philters and incantations," he is evidently presenting that idea which the conversations of Socrates impressed on his own mind. He seems almost to confess this of himself when he informs us, how Socrates triumphantly appealed to the marked devotedness of his followers, in saying, "Why think you that this Apollodorus and Antisthenes never quit me? Why too, that Cebes and Simmias come here from Thebes? Be assured, that this is not without many philters, and incantations, and spells."[4]

To the same honourable band of attached disciples might be added many other names afterwards renowned in the annals of Grecian history and literature. Isocrates, Aristippus, Antisthenes, each of whom became afterwards masters themselves, were content to follow in his train. Antisthenes especially, who, by perverting the Socratic simplicity of life into a profession of austerity, became the founder of the Cynic school, was never from his side. He would walk from the Piræus to Athens, a distance of about four miles, every day, in order to be with Socrates. And whilst Cebes and Simmias came from Thebes, Euclid, the founder of the Megaric sect, was not deterred by the bitter hostility between Athens and his own city of Megara, from seeking the society of Socrates at the hazard of his life. Even during the war, when the Megareans were excluded by a rigid decree, he continued his visits to Athens, adopting, it is said, the disguise of female attire, and so passing unobserved into the city at nightfall, and returning at daybreak.[5] The same individual gave still more conclusive evidence of his zealous attachment to Socrates afterwards; when he opened his house and his heart to receive, at Megara, his brother disciples, in their panic on the death of their master. So strong was the tie of reverence and affection which subsisted between the philosopher and those whom he drew around him. They formed, indeed, a sort of select family, each of whom was engaged in the pursuit of his own peculiar employments and tastes in the world, whilst all looked up to Socrates as their father and head, and ever recurred to his society as to their common home.

This domestic intercourse subsisted in the midst of a city harassed with jealousies and dissensions, and with severe afflictions of war and pestilence. Socrates remained unmoved through all these convulsions of the city, preserving a constant evenness of temper, so that Xanthippe could testify of him, that she never saw him returning at evening with a countenance changed from that with which he left home in the morning.[6] Nor could even the merriment of which he was sometimes the object, discompose his settled gravity and good humour. On one occasion, returning from supper late in the evening, he was assaulted by a riotous party of young men, personating the Furies, in masks, and with lighted torches.[7] The philosopher, however, without being irritated by the interruption, suffered them to indulge their mirth; only he required them to pay that tribute which he exacted from every one that came in his way, to stop and answer his questions, as if he had met them in the Lyceum, or any other accustomed place of his daily conversations. Himself sound in mind and body, (for his habitual temperance saved him from the infection of the plague which so obstinately ravaged Athens,) he was enabled to give advice and assistance to all of his country in the midst of the physical and moral desolation, in which every one else seems, more or less, to have participated.

Thus were the years of a long life quietly and usefully spent; and he had nearly reached that limit at which nature herself would have gently closed the scene of his philanthropic exertions, when the hand of human violence interposed to hasten the approaching end.

[7] Ibid. c. 29.

The annals of party spirit at Athens had already recorded many a deed of dark and wanton cruelty. But they were yet to be stained with the iniquity of a persecution even to death, of him, who had been the greatest benefactor and ornament, not only of Athens, but of the whole community of the Grecian name.

The banishment by ostracism had this redeeming merit, that it was an avowal in the face of Greece, of the envious and factious spirit, which drove from the state the individual whose talents or virtues too greatly distinguished him from among his fellow-citizens. The enmity to which Socrates fell a sacrifice, exhibits a deeper character of malignity; inasmuch as it masked itself under a hypocritical zeal for religion and virtue, and thus courted public sympathy for proceedings, against which every voice in Athens and in all Greece should have indignantly protested. Ostracism, again, was content to remove the obnoxious great man from the eyes of his fellow-citizens. The attack on Socrates was satisfied with nothing short of the destruction of its victim.

It was in the midst of the tranquil, but busy course of his daily engagement, that Socrates was suddenly arrested, and without, it seems, any previous intimation of the intended attack, summoned to the portico of the king-Archon, to answer a charge of impiety.[1]

The accusation was in this form: "Socrates is guilty of the crime of not acknowledging the gods whom the state acknowledges, but introducing other new divinities: he is guilty also of the crime of corrupting the young." The penalty proposed was death. It has been commonly supposed that the charge was laid before the court of Areopagus. But it would appear rather, from the course of the trial, to have been before one of the popular courts, and probably, from the great number of dicasts or jurors who voted on the cause, before the principal court, the Heliæa.

The circumstances connected with the accusation remain, after the utmost inquiry now possible, involved in considerable mystery. We are told that Melitus was the accuser, and that he was supported in the prosecution by Anytus and Lycon. These three individuals are also said to have represented distinct classes of persons interested in the proceedings; Melitus, who was himself a poet, appearing in behalf of the offended poets; Anytus, a wealthy tradesman and demagogue, resenting the affronts of his brother-tradesmen; Lycon, an orator, or politician by profession, standing up as the assertor of the pretensions of his factious order. But these particulars, though they may account to us in a great measure for the success of the prosecution, do not exhibit the secret agency by which it was effected. The accusers themselves were men of no note or importance in the state. Melitus was a young man; a vain and weak person, it seems, of whom nothing more is known than that the accusation was made in his name. Nor of Anytus and Lycon have we anything to mark the importance, beyond the fact, that the former was included, together with Alcibiades and Thrasybulus, among the persons exiled by the Thirty, and the notice taken of him by Plato, where he represents him the inexorable foe of every thing in the shape of a philosopher, and as parting from a conversation with Socrates in anger.[2] Merely personal offence, however, could not have given sufficient pretext or weight to so grave an accusation. Nor can we suppose that it was even the combined interest of the three classes represented by the three accusers—the poets, the tradesmen, and the orators—which carried the condemnation of so respected a person. The ground of the attack must lie deeper; and the men whose names appear so prominently in this fatal conspiracy against the life of the venerable old philosopher, could only have been the puppets moved by some secret and more commanding force. The trial would seem to have been only a solemn pageant, exhibited before the public, as a prelude and justification of a deed of murder already resolved on by its real though invisible perpetrators. Whilst the charges themselves, as set forth by the nominal accusers, were but feebly sustained, it is evident that no defence, however just and able, could have availed to avert the sentence of condemnation. The body of jurors before whom the cause was heard, appear to have been disposed to acquit the accused, if we may judge from the number of votes which were given in his favour; and yet the majority were overruled. This in itself would lead us to think that some secret influence had been exercised, to obviate the chance of failure of the ordinary ostensible means of judicial assault. And so Socrates himself appears to have felt; if Plato and Xenophon have faithfully reported the substance of his reply to the accusation in their Apologies. His defence, as there represented, is that of one who retires, on his own consciousness of right, from a bootless conflict with adversaries who are not to be appeased by argument and persuasion. It does not set forth the strength of his cause as against an opponent, but simply asserts the truth and merit of the course of life which he had been pursuing.[3] The sentence accordingly excites no surprize in him. He yields himself up as to the sweeping of a tempest, with which it is vain to parley. Would we then explore the circumstances of the trial and condemnation of Socrates, we must obtain a deeper insight into the moving power of Grecian politics,—the spirit of the heathen religion, and the mode of its action on the conduct of states and individuals. This appears to be the proper solution of the case of Socrates. The circumstances of the case evidently point to this. And though, from the want of information, we cannot very distinctly trace the working of the religion of the times in the particular instance before us, we may, from a closer consideration of the facts, not unreasonably suspect its active operation and instrumentality.

Speculators have sometimes spoken of the mild and tolerant spirit of paganism. The observation, however, is superficial and untrue. The facility with which the polytheistic worshipper transferred his offerings and prayers to every new idol, has been mistaken for a readiness to admit any variation from the established worship, or any freedom of opinion respecting divine things, without offence. The contrary is the fact. The heathen, resting his religion on ancient tradition[4] and the authority of the priests, and not on any intrinsic evidences of its truth, could not but feel a jealousy of any departure from what he had thus received, or any attempt to bring the subject into discussion. It was not only the primitive Christians that were stigmatized by heathens as atheists, because they renounced the divinities of the heathen creed, but the same reproach was long before cast upon those among the heathens themselves, who, with however pious disposition, ventured to speculate on religion. A traditionary religion will tolerate any laxity of thought or conduct which professedly admits its authority, whilst it peremptorily puts down every thing which impugns the principle of absolute deference to its authority. Thus we shall find, that, where that principle is carried to the utmost, there co-exists with it a scarcely concealed infidelity, and an unrestrained licentiousness of conduct; and, at the same time, also an extreme sensitiveness in regard to deviation from the orthodox profession and language. We have unhappily seen this in those Christian countries, where the true faith, the principle of devout submission to the word of God, has been transformed and perverted into a doctrine of implicit deference to the authority of the ministers themselves of that word. There,—as, for example, in Spain and Italy,—where the authority of the church is bowed to most submissively, practical infidelity and immorality shew their front with impunity, whilst the expression of opinion or argument on questions of theology is discouraged and silenced, if no longer now, as once, crushed at its outbreak by the dark terrors of an Inquisition. The same fact was intensely exemplified in heathen Athens. At no place was piety, as piety was understood by heathens, more in honour. No state boasted such a tradition of sacred associations as Athens. In none were there so many festivals and solemnities of religious observance, as in Athens.[1] In none did the priests of religion hold such sway. Witness their power over Alcibiades, at the moment of his political triumph, and amidst the caresses and admiration of his fellow-citizens, when he felt himself obliged to relinquish his command in Sicily, and desert his country, rather than encounter at home the threatened prosecution for his profanation of sacred things. Witness their power again in the instance of the same Alcibiades, at his restoration to the command of the army, when, to conciliate their favour, he delays the urgent expedition, and keeps the soldiers under arms along the road by which the sacred procession passed from Athens to Eleusis. Witness further, the frequent prosecutions at Athens on charges of impiety of which we read, and of which we have monuments in extant orations. But, amidst this strictness of external profession, in no place was there a more entire license as to practical irreligion. Their festivals abounded with rude and obscene mirth. Their drama, whilst it inculcated in direct precept the belief and worship of the gods, indulged in the most profane ribaldry and ludicrous representation of sacred things. Yet were these follies and excesses tolerated, because under them a regard was still maintained to the authority which upheld the religion, as in the "mysteries" and "moralities" enacted with the connivance of the papal power in modern times; and the people at large were satisfied with a religious system, which was exhibited to them as so good-humoured and humane. They were tolerated, indeed, but not without the like injury to the religious feelings, as in the parallel cases, where a corrupted secular Christianity has ventured on the like palliations of its despotism. For all the while the people were losing their hold of the popular religion. Those who thought at all on the subject, either rejected it altogether, or accounted it a mere matter of opinion and external ordinance; whilst those, on the other hand, who were content to receive every thing traditionary as divine on the mere principle of deference to the priests, readily engrafted every new superstition on the received religion. Thus, whilst infidelity and superstition grew up at Athens, and flourished together, and often perhaps in the same mind, the connexion between religion and morality was altogether lost sight of and dissolved. Men began to regard themselves as devout, and friends of the gods, whilst they were committing deeds of violence and lust, and blindly and wickedly endeavoured to support the cause of religion by forcible suppression of the truth, and persecution of those who subjected their tenets or their rites to the test of inquiry. Thus, whilst Aristophanes was amusing the people, not of Athens only, but from all parts of Greece, at the public festivals, with ludicrous representations of the popular theology, and loosening more and more any existing associations of reverence towards the objects of their worship, severe prosecutions were carried on from time to time against all who in any way made religion a matter of debate, or seriously brought it into question with the people. The same persons can take part in the vulgar low jest, and shew their real contempt of religion by their carelessness about oaths and the practical duties of religion, and yet join zealously in the prosecution of offenders against established notions of religion. It is the same habit of mind in both cases; a habit of looking at religion as a general rule of orthodox profession,—as a rule binding on a community, and a test of its soundness of doctrine,—rather than as a personal concern, and a trial of the spirit of a man. "He has brought Gentiles into the temple, he has abolished circumcision, he has profaned our religion," was the outcry against St. Paul; and yet these same persons thus clamorous against the apostle, were minding earthly things all the while, sticklers for externals, yet idolaters in their personal religion, as men of covetousness, and slaves to the appetites of the body.

[1] Plato, Thætet. ad fin. Euthyphro. et alib. The king-Archon was a sort of minister of state for the department of religion—the representative, under the democracy, of the priestly office of the king during the monarchy at Athens. See Demosthenes, c. Neær. p. 1370, ed. Reiske.

[2] Xen. Hell. ii. 3. 42, 44.—Plato, Meno.

[3] See the same exemplified in what Socrates is made to reply to Callicles in the Gorgias of Plato, p. 162, τοσοῦτον μέντοι καὶ ἐγω οἶδα ὅτι παθος παθοιμι ἂν εἰσελθὼν εις δικαστήριον, κ.τ.λ.

[4] Demosthenes, in his Oration against Neæra, p. 1370, speaks of a column erected in the temple at Limnæ, ἐν τῷ ἀρχαιοτάτῳ, ἱερῷ τοῦ Διονύσου καὶ ἁγιωτάτῳ, and standing in his time, which stated, among other things, ἵνα κατὰ τὰ πάτρια θύηται τὰ ἄρρητα ἱερὰ ὑπὲρ τῆς πολέως, καὶ τὰ νομισμένα γίγνηται τοῖς θεοῖς εὐσεβῶς, καὶ μηδὲν καταλύηται, μηδὲ καινοτομῆται: and he sums up the account with εἰδῆτε, ὡς σεμνὰ καὶ ἅγια, καὶ ἀρχαῖα τὰ νόμιμά ἐστιν.

At Athens, accordingly, though there was no freedom of religious opinion, the religion might be employed to excite festive mirth, and gratify the levity and licentiousness of a dissolute yet intellectual populace, amidst the charms of poetry and music and the solemn graceful dance. For then the associations of deference to the mysterious agency which held together the traditions of the popular creed were not violently broken asunder. There still remained in the minds of the people an awe at the indefinite mystic truth, hidden under the embroidered veil held before their eyes. They knew that the splendid drama of religion, which at once gratified their refined intellectual taste and their sensibility, was not the whole of their religion. They had also the Eleusinian mysteries; rites of religion performed in secrecy, and fenced round with the terror of death to him that should divulge them; delegated to a few, the initiated only, and incommunicable to the vulgar; of which the popular rites were but the rude symbols.[2] The popular worship might wear the form of caricature, the grotesque, the farcical, and even the profane, as being merely the pantomime in which some recondite interior religion was dimly and wildly shadowed. The people laughed at what they saw and heard at their festivals. But amidst their laugh there was evidently a feeling of awe, which subdued the luxury of their mirth; a consciousness that, whilst they sportively shook the chain of their superstition, its iron entered into their soul. We see, on the other hand, Aspasia, the favourite of Pericles, at the time of the greatest popularity of that most popular leader, summoned before the courts, to answer a charge of impiety, and scarcely defended by the eloquence and the tears of Pericles himself, from the inexorable power, whose vengeance she had provoked by her philosophical speculations. Protagoras, admired as he was and courted at Athens for his talents in his profession of a Sophist, was expelled from the city and borders of Attica by the Athenians, and his books were collected by proclamation and burnt in their agora, for his avowed scepticism as to the existence of the gods.[1] Æschylus, whose very poetry is instinctive with religion, was accused before the Areopagus of divulging the mysteries in one of his tragedies.[2] The philosopher Anaxagoras, like Galileo under his papal inquisitors, suffered imprisonment at the hands of Athenian persecutors, for having asserted the material nature of the heavenly bodies, and only escaped death by the intervention of Pericles, and by exile from his adopted home. The extent again, to which prosecutions for offences against the popular religion could be carried at Athens, is shewn in the number of persons who were imprisoned on suspicion of being implicated in the impieties charged on Alcibiades, and the execution of so many, on that occasion of panic, on the unsupported evidence of secret informers. Lastly, not many years before the accusation of Socrates, Diagoras the Melian, and Theodorus of Cyrene, were branded with the epithets of atheists; and the former was forced to fly from Athens on a charge of profanation of the rites, with the price of a talent set on his head for any one who should kill him. And long after the time of Socrates, the same spirit subsisted to drive Aristotle from the Lyceum, and later still, to intimidate the speculations of Epicurus. So strictly was the *authority* of the established worship guarded by a jealous and watchful inquisitorial power, in a state which boasted of its perfect liberty of speech, its παῤῥησία, above all others.

[2] Isocrat. Panegyr. p. 54. Ἃς οὐχ οἷόντ' ἄλλοις ἢ τοῖς μεμυημένοις ἀκούειν . . . καὶ τὴν τελετὴν, ἧς οἱ μετέχοντες περί τε τῆς τοῦ βίου τελευτῆς, καὶ τοῦ σύμπαντος αἰωνος, ἡδίους τὰς ἐλπίδας ἔχουσιν.

In fact, there was no liberty of speech on this subject in Greece. Every thing relating to religion was to be received as handed down from former ages; as the wisdom of an immemorial antiquity, borne along on the lips of the priest and the prophet, or impressed on mystic rituals, the hereditary trust of sacred families, or symbolized in the pomp and pageant of festivals and games, in the graceful majesty of temples, and the solemn shadows of sacred groves. The inward devotion of such a religion naturally took the form of silence, and reserve, and awe. It was concentrated in the simple dread of profanation. The more superstitious indeed a people is, the more necessary is it that the rites of their religion should be strictly shut up from all inquiry, and a feeling of reserve should be inculcated as essential to the religious character. It is the indefiniteness of superstition that holds together the system. Let any one part of the vaguely-floating system be touched too palpably, and the whole crumbles. Thus it has been found, that superstition and infidelity have always gone hand in hand. Diagoras was made an atheist from being at first superstitious. The Athenian people, in like manner, from their superstitious character, were peculiarly exposed to a reaction of impiety. And it was but a wise policy, therefore, that the religion of Athens should be jealously guarded with an awe forbidding all inquiry into its truth.

The colloquial and lively spirit of the Athenians mitigated the intensity of this feeling in the minds of the people at large; and the managers of the system were fain to relieve it, by blending recreation, and mirth, and interesting spectacles, with its public celebration. Grecian superstition accordingly, whilst it bore the essential marks of its oriental origin, in the submissiveness exacted of its votaries, and its mystic reserve, assumed also the mask of cheerful expression characteristic of the genius of the people. Still we see that submissiveness and that reserve strongly marked in the stern denial of the right, not only of private judgment on questions of religion, but even of bringing such questions at all into discussion.

Now, though, as we have already observed, we cannot distinctly trace the steps by which this spiritual despotism was brought to bear on Socrates, we cannot doubt that his was a case which must have attracted its notice. During more than forty years, Socrates had been seen at Athens, going about among all classes of the people, exciting among them a spirit of moral inquiry, urging on them the importance and the duty of self-knowledge, of taking no opinion on mere hearsay, or indolent and self-satisfied trust, but of bringing every thing to the test of discussion and learning, of acquainting themselves, as their first step to knowledge, with the depth and extent of their ignorance. Observers saw in this extraordinary teacher, one of their own citizens, educated in their own institutions, familiar with the habits of Athenian life, ever at home among themselves, recommending himself alike to the young and the old, by the honest though quaint dignity of his manner, and the interest and charm of his conversation. He was not, like Anaxagoras, or Protagoras, or Prodicus, a stranger sojourning among them; a philosopher or rhetorician by profession, or one pursuing philosophy as a trade and a source of subsistence, waiting to be resorted to and courted by the affluent and noble, and reserving himself for occasions of display or profit; but he was found, an Athenian among Athenians, in the market place, in the streets, in the work-shops, at the tables of the wealthy, himself seeking out persons to instruct, asking questions of all around him, and engaging them, even in spite of themselves, in conversation with him.[3] In other teachers, philosophy had spoken, according to the observation already made, as from an oracular shrine, to those only who came to inquire of it as votaries and disciples. With Socrates, philosophy walked abroad, insinuating itself into the scenes and business of daily life, and drawing forth the secret treasures of men's minds with its own hands. According to that homely but apt illustration of his mode of teaching, which he was so fond of employing, from midwifery, his method freely offered its services in assisting at the birth of the thought with which the pregnant mind was labouring. He busied himself, he used to say, with the officiousness of his maternal art, in exploring the genuineness of the fruit of the intellectual womb, which his dexterous questions had brought to light.[1] Such a person then could not but fix on himself the eyes of every attentive observer of the state of society in Athens. Such teaching evidently could not but have a very considerable influence on public opinion. Particularly when he was seen to be acceptable to men of all parties in the state, to the leaders of the aristocratic faction as well as the humblest citizen, it could not but be inferred that his influence was not a transitory one, dependent on the predominance of any party, but that it would reach to the fundamental constitution of the society at large of the city, and be a leaven of fermentation to the whole mass. What, then, it would naturally be asked, must be the effect of such a teacher on existing opinions in religion? He taught, indeed, that men should acquiesce in what was established in religion; that they should inquire no further here than what simply was the law of the state. He treated, too, the popular imagery of religion with respect. For he would often clothe his instructions in the language of the legends and traditions of their mythology. Nor did he attempt to explain them away, though he waived all discussion of them. He was seen, too, on all stated occasions, sacrificing at the altars of the gods, and joining in the rites.[2] But, it would be asked, if the citizens were taught to examine into received opinions generally, would they abstain from carrying this principle into the subject of religion? Would they continue still blindly and submissively to follow the voice of authority? Would they not rather, so far as they were disciples of Socrates, begin to speculate on divine things, abandoning that reverence which they had hitherto maintained for the objects of public worship, disputing and discussing without reserve, and exposing to the vulgar gaze what had been all along venerated in mystic silence, and under the veil of symbol? The mercurial temperament of the Athenian was just the soil in which the seeds now scattered by the hand of Socrates might be expected to vegetate. The excessive prosperity, too, of Athens, during the fifty years immediately following the Persian war, and then its condition of struggle against internal faction and the confederate arms of Peloponnesus, were circumstances calculated to foster the profane irreligious spirit in a light-hearted people. Then, instances were not wanting of young men, the intimates of Socrates, and whose minds had been especially cultivated by conversation with him, who proved in the end traitors to the religion, as well as to the civil liberties of their country. Critias,[3] afterwards one of the thirty tyrants, and Alcibiades, at once the pride and the pest of his fellow-citizens, whom they loved and hated, and banished and longed for by turns, were striking evidences to the superficial observation of the evil apprehended from the teaching of Socrates. For here were young men of genius, susceptible by nature of the fullest influence of the lessons of the philosopher. And yet these had failed under his hands. What, therefore, might not be expected of minds of inferior order? How would not the religion and the institutions of the city fall into profane neglect and contempt, should the Socratic spirit of inquiry be imbibed by the next generation of citizens? The observation, indeed, was only a very superficial one, which would infer from such instances the evil of the teaching which these individuals misapplied. Still it is plain, that such cases were pointed at with invidious reference to Socrates and philosophy in general. We find the orator Æschines attributing the death of Socrates to the circumstance of his having educated Critias;[4] not that he must be supposed to have believed this to have been the whole account of the trial and condemnation of Socrates; but as an orator, he states for the purposes of his argument, what he conceives would be readily believed as part of the account of that event. Plato also studiously addresses himself to the defence of philosophy, from objection on this ground, with evident allusion to Alcibiades and the like cases; arguing that the same individuals who were most susceptible of the good of philosophy, were also such as would be the most apt to abuse it. And probably he had the same design, and refers to the degenerate sons of Pericles himself, as an instance in point to those who cherished the memory of that great man, and of the times in which he flourished, to show that the philosopher was not to be held responsible for the extravagances and vices of the disciple.[5]

[1] Diog. Laer. ix. c. 8. Cic. De Nat. Deor. i. 23. See the story of the daughter of Neæra, as told by Demosthenes, in his oration against Neæra, p. 1369. She had been married under the pretence of being an Athenian citizen, to an Athenian who served the office of the king-archon. As the wife of this officer of the state, she was admitted to the rites of religion, and solemnly inducted into the mystic temple of Bacchus at Limnæ. But it was unlawful for any but a true-born citizen to enter into the temple, or to witness the rites; and her husband consequently was tried before the court of Areopagus for the impiety, and only escaped on the plea of his ignorance of the fact, and on the condition of his dismissing her from his house.

[3] Plato, Euthyphro. 3 d. Ἐγὼ δὲ φοβοῦμαι, μὴ ὑπὸ φιλανθρωπίας δοκῶ αὐτοῖς ὅ, τι περ ἔχω ἐκκεχυμένως παντὶ ἀνδρὶ λέγειν, οὐ μόνον, ἄνευ μισθοῦ, ἀλλὰ καὶ προστιθεὶς ἂν ἡδέως εἴ τις μου ἐθέλοι ἀκούειν. Op. t. i. p. 6. Xenoph. Mem. i. 2. Ἀλλὰ τῶνδέ τοι σε ἀπέχεσθαι, ἔφη, δεήσει, ὦ Σώκρατες, τῶν σκυτέων καὶ τῶν τεκτόνων καὶ τῶν χαλκέων, καὶ γὰρ οἶμαι (Critias is speaking) αὐτοὺς ἤδη κατατετρίφθαι διαθρυλλουμένους ὑπὸ σοῦ. P. 21.

The exhibition of the comedy of "The Clouds," appears to have been designed to bring before the people the supposed evil tendency of the teaching of Socrates, as exemplified in such distinguished instances. It was produced in the year B.C. 423, when the philosopher had attained his forty-seventh year, and was at the height of his reputation throughout Greece, and about twenty-three years before his death. There we have Socrates introduced by name under broad caricature, as the representative of the class of sophists, and a consummate master of the arrogant pretension, and sordid cunning, and impiety of the class. The clouds are his only divinities. A profligate spendthrift youth, and a dotard father, are his dupes. The inquisitive method which Socrates practised, is also held up to ridicule and contempt, by identifying it with the frivolous questionings of the grammarians, and dialecticians, and rhetoricians of the day, and with the perverse sophistry which held truth a matter of indifference, or, which amounted to the same thing, called every man's opinion truth, and boasted of its skill to make the worse appear the better cause. It was but too evident to Athenian spectators at least, that the Socrates of Aristophanes was not the Socrates whom they had been accustomed to see and converse with in real life. And the play accordingly failed at the first exhibition. Not all its charms of poetry, and humour, and skilful composition, could obtain for it a favourable reception. Though Aristophanes was aware that the portrait which he had drawn, was not a portrait of the individual, but of the class, there can be little doubt, that he calculated on the sympathy of the people, in giving the name of Socrates to his personification of the sophistical spirit; and that he felt it necessary to depreciate the influence of Socrates as the commanding influence of the day, by attributing to his method all the vices of the schools of the sophists. Socrates is honoured and complimented in the very attempt to weaken the respect for his instructions, and to awaken a clamour against him. The failure of "The Clouds," at the first representation, and one account adds, even at the second, (for the play is said to have been retouched for the third time), has been attributed to the influence of Alcibiades. Alcibiades indeed has been supposed by some commentators to have been no less the object of attack in the play than Socrates himself, and to have been designated under the name of Phidippides, the youthful and accomplished victim of the sophist. There are certainly some traits in the character of Phidippides, which would seem to point at Alcibiades, whom perhaps the poet, bold as he was, could hardly venture to bring on the stage by name or closer description at this particular time. And we may perhaps justly allow some weight to party influence in neutralizing the effect of "The Clouds" at its first exhibition. Still, when we observe in other instances the great power which the comic muse could wield against a political opponent, as in the attack on Cleon in "The Knights," we cannot but think that there was some strong countervailing feeling in the estimation of Socrates himself. If the account of Ælian be true, Socrates could join in the laugh raised against him; for he was present in the theatre during the acting of the play, and finding that he was the object of attraction, placed himself where all could command a view of him.[1] He knew, and every one in Athens knew, that he was a very different person from the sophists with whom the play identified him. They indeed were corrupters of the young; for they unsettled every established principle in the minds of the young, and gave no substitute for what they profligately swept away. They left the young to be drifted away by the tide of their passions, with no criterion of truth or of right beyond the present opinion or the present interest. But Socrates, whilst he taught the young to inquire into the truth of their opinions, lessened their presumption and self-confidence, by shewing them how apt they were to mistake mere assumptions for knowledge, and to be conceited of their ignorance. His object was truth, and accurate knowledge. He stated difficulties and objections, but not in the spirit of a sceptic, but in order to awaken curiosity, to clear away confusion of thought, and inculcate sound principles of judgment and conduct. He could well then laugh at the jest which glanced from him to its proper objects, the sophists themselves, the very persons against whom his whole teaching was directed. He felt doubtless that he had a hold on the people at large, which the sophists had not. They were for the most part known only to the great and wealthy; those who could receive them into their houses, as they went from city to city through Greece; who sought their society as patrons of literature, or aspirants after political distinction, and who could pay for their instructions.[2] He on the contrary was accessible to all. He would receive no money from any one. He was the frequent guest of the rich; but he was no less the associate of the artizan and the poor. And too many must have been present in the theatre, when the Socrates of "The Clouds" was amusing the audience by his sleight-of-hand philosophy, who would remember the real Socrates as a man of honesty, and truth, and disinterested benevolence, from whom they had received much useful counsel from time to time, and whom they had ever found affable, and at leisure to enter into their feelings and views with patience and kindness. If we compare the Socrates of the Memorabilia of Xenophon with the Socrates of "The Clouds," we may judge how great was the contrast to those who compared the well-known philosopher of the agora with his portrait as drawn by Aristophanes. If we can smile at the caricature of "The Clouds," and yet love the excellent moralist of the Memorabilia, we may also conceive how harmless the satire of Aristophanes would really be against the object of it; whilst the jokes of the poet, true as to the personal peculiarities of the philosopher, amused a volatile and clever people. For them to have confounded Socrates with the class of sophists, would have been in them the like palpable mistake, as it would be to confound the philosopher Bacon, on account of some points of resemblance, with the alchemist and empiric of the preceding ages.

[3] Critias is placed by Sextus Empiricus among the atheists. He is said to have resolved all religion into the enactments of legislators providing against the secret commission of crimes, by inculcating the all-seeing power of the gods. He gives also several lines from a poem of Critias to this effect. Adv. Math. lib. viii. p. 318.

[4] Æschin. con. Timarch.

[5] See the Protagoras and Repub. vi.—Xenophon adverts in like manner to the charge of corruption as supported by the instances of Critias and Alcibiades. Memor. i. 2. See also the conversation which Xenophon reports between Socrates and Hippias. Isocrates, in *Busir.* p. 222, c. with the like feeling, *denies* that Alcibiades was educated by Socrates; meaning, it seems, that Alcibiades was too short a time with Socrates to be benefited by the instructions of the philosopher

It might seem matter of reproach against Aristophanes, that, in selecting the name of Socrates to represent the sophistical spirit which had then so largely corrupted the education and the government of Athens, he pointed the shafts of the comic muse against the very person who was in truth its most successful antagonist. In such a view of the case, however, sufficient justice would not be done to the discernment of the poet. He shrewdly observed in Socrates the master genius which would ultimately cast into the shade all those busy professors of the art of education, who, under the name of sophists, or professors of all knowledge, were then attracting the notice of the world to themselves and their doctines. Socrates, in himself, Aristophanes could not but admire and recommend to the imitation of his country. He doubtless knew Socrates to be a true patriot no less than himself,—to be steadily aiming to bring back the Athenians to the purity of their institutions, from which they had so sadly degenerated, by his instructive conversations, as he was by the satirical strokes of the drama. Socrates, too, appears to have been his personal friend; for Plato introduces them in his Banquet as meeting on terms of intimacy, about the very time of the exhibition of "The Clouds." But with that freedom which the state of manners, under an absolute democracy, sanctioned and encouraged, Aristophanes did not scruple to bring even the revered name of Socrates on the stage, to give the due point to his satire. He overlooked the individual, the Socrates with whom he familiarly conversed, and presented before the spectators what he saw in Socrates, the living speaking impersonation of the influence of education on the character of a people, for good or for evil. Anaxagoras, or Protagoras, or Prodicus, or any other of the well-known philosophers or sophists of the day, might have occupied the foreground in the comedy of "The Clouds;" had the poet sought to give merely a fugitive sketch of the sophistical spirit of his times, or to single out for ridicule some of its external superficial features. This is what Plato has done on many occasions, and especially in that most animated picture in the dialogue entitled Protagoras, where he groups together the figures of the leading sophists in such admirable relief with each other, and such happy contrast with the unpretending but dignified form of his own loved master and friend. Such a view, however, could not have answered the design of Aristophanes in his play of "The Clouds." His object was to seize the deep, influential characters of the system of education which was then extending itself throughout Greece, and especially as it was manifested at Athens, the great school of all Greece. Naturally, therefore, and wisely, he fixed his eye on an Athenian—and that Athenian, Socrates,—not only as the first Athenian who had appeared in the office of a philosophical instructor, but who, as an Athenian, gave to his lessons the character of Athenian civilization, and fitly exemplified the influence of philosophical education in the hands of an Athenian, and as operating on Athenians.

The poet, indeed, as addressing the eye and the ear of the ordinary observer, and not Athenians only, but strangers of the Grecian name from all parts, mingles with his colouring some playful lights borrowed from the forms of the well-known professional sophists of the day. But neither are these representations, nor the allusions which he makes to the real eccentricities of manner and uncouthness of person in Socrates, the points on which he desires to fix the attention of the theatre. It is the important modification of the Athenian character, under a system of education which had now reached its maturity. Under the administration of Pericles, that system had already infected the policy of the state, and perverted its courts of justice into sinks of corruption and oppression. Now, at length, it was found domesticated at Athens in the sanctuary of private life. An Athenian had appeared in the character of a professor of philosophy; and around him were gathered citizens of all ranks, from the noble youth who aspired to the helm of the state, and the wealthy patron of literature, to the mean artizan who worked at the forge, and the drudge of the market. What was further to be observed now, was, that the system came recommended by the eloquence of lively and exciting conversation. And how powerful must have been such conversation, as it came forth from the lips of the speaker in the elegant and terse Attic idiom! It was no wonder, therefore, that the comic poet should have seized this moment for portraying the danger which he anticipated to his country from the fashionable education of the day, and thrown all the force of his ridicule on the most attractive form in which it then presented itself, as displayed in the personal teaching and example of Socrates.

---

[1] Ælian, Var. Hist.

[2] Plutarch well characterises the teaching of Socrates, in speaking of him, as ἀνδρὸς ἀτυφίᾳ καὶ ἀφελείᾳ μάλιστα δὴ φιλοσοφιαν ἐξανθρωπήσαντος. De Socr. Gen. p. 301.

The testimony of Plato is to the same effect. Plato has not given us an exact portrait of Socrates any more than Aristophanes has; for he has evidently transferred to the Socrates of his Dialogues, not less of his own cast of mind and manner, than Aristophanes did to the Socrates of his comedy, of the general tone of the sophists. And this is to be accounted for, as in the case of Aristophanes, from the fact, that Plato regarded Socrates as the impersonation of the philosophy of the times. He felt that, to give his own doctrines a proper authority and weight, he could not employ a more effectual organ than the tongue of him who had first given to philosophy an Attic expression, and from whom it would henceforth derive its proper Grecian character.

But though the drama of "The Clouds" was unsuccessful as an attack on Socrates, if it were intended as such, or as an attack on the sophists under the name of Socrates, which is the more probable view of its design, it must not be supposed that the play produced no effect unfavourable to Socrates. The tradition, that Aristophanes was employed by Anytus and Melitus to write down Socrates, does not seem altogether without reason; though it can hardly be literally true, when we look to the distance of time which intervened between the production of the play and the accusation. In the *Apology* of Plato there is an allusion to the prejudice excited in the young men by the representation given of the philosopher in this play. Nor had "The Clouds" been the only attack on Socrates by Aristophanes; not to mention other comic writers who had made him the object of their humour. In the year 405, not more than five years before the prosecution, the play of "The Frogs" had been exhibited, in which a pointed allusion is made to the influence of Socrates in terms of reprobation.[1] In the mean time, also, the same note had been struck; for the play of "The Birds" was produced in the middle of this interval between "The Clouds" and "The Frogs," in the year 414; and in that again the Athenians are warned against the corruptions and enchantments of the philosopher.[2] And it is very possible that many who lived to witness the formal accusation of Socrates, might have received their earliest prejudices against the philosopher by what they heard in the theatre then,—prejudices, too, which the course of events, the miseries of the Peloponnesian war, and the anarchy consequent upon it, may have ripened into exasperation.[3] For they saw their country fallen from its proud station in Greece, to the condition of a dependent state; and they were led to ascribe their misfortunes to a change of habits since the days of Marathon and Salamis,—to their having deserted the palæstra and the field, and become, from a body of devoted patriots and soldiers, students of rhetoric and masters in debate.[4] During all this time Socrates continued the unrivalled teacher of the youth of Athens; increasing, indeed, in renown and popularity; and surrounded by a number of students of philosophy and political science from all parts of Greece. He had, in fact, converted Athens into a university of Greece. For though he had no professed school,—no φροντιστήριον, as Aristophanes jocosely represents the scene of Socrates amongst his disciples,—no regular place of meeting, such as Plato had in the Academia, and Aristotle in the Lyceum;—there might be seen around him in familiar conversation, in every part of the city, day after day, the statesmen, and orators, and generals of the republic,—philosophers of established repute from other cities,—the sons of the noblest families of Athens as well as of the humblest citizens,—and the resident foreigners and occasional visitors of the city; some seeking instruction in the art of government, some investigating by his guidance the chief good of man, some studying the theory of eloquence and criticism, some exploring, by the light of his searching questions, the depth of metaphysics, and the subtile speculations of the earlier philosophers; all according to their different pursuits, and in their different degrees, receiving information and general mental culture from the great Athenian sage. Those who clung to the thought of Athens in its days of military glory and empire, would painfully observe how great a change had taken place in the internal habits of the city. Formerly it was enough for the intellectual improvement of the youth, that in childhood he had the grammarian for his instructor, and as he grew up to manhood, was consigned to the poets;[5]

> τοῖς μὲν γὰρ παιδαριοισιν
> ἔστι διδάσκαλος ὅστις φραζει, τοῖσιν δ᾽ ἡβῶσι ποιηταί[6]

Now even the slaves were becoming literary. The distresses of war had occasioned the addition to the roll of citizens, of many even from that class. And these might be seen, as the comic poet represents them, "each with his book, learning clever things;"

> βιβλιόν τ᾽ ἔχων ἕκαστος μανθανει τὰ δεξιά.[7]

Formerly, their wise men were obliged to leave the ignorance and rudeness of their own city, and learn philosophy by foreign travel. Solon had brought back with him from his travels the wisdom of Crete and of Asia to enrich their code of laws, but had not given philosophy a domicile at Athens; had not affected domestic life there with its refinements.

[1] Aristoph. Ranæ, 1487. [2] Aristoph. Aves, 1282, 1554. [3] See Thucyd. iii. 82, ἐν μὲν γαρ εἰρήνῃ καὶ ἀγαθοῖς πράγμασιν, κ.τ.λ.

[4] In Xenoph. Mem. iii. 5, the younger Pericles asks Socrates how the Athenians are to be brought again to become enamoured of their ancient virtue, glory, and happiness; and afterwards he expresses his wonder how the state ever began to decline. Socrates imputes their degeneracy to their neglect of the institutions of their ancestors. The particulars mentioned are, want of respect to elders, neglect of bodily exercises, even to the ridicule of them, insubordination to authorities, mutual irritation, envy, quarrelsomeness, litigation, covetousness, incompetence of their generals.

[5] If we except the profession of the Sophists, when at its height of public favour, skill in the composition of tragedy was the most highly rewarded of all talents at Athens. Plato, *Laches*, 183, b. p. 169. The poets of Athens, therefore, were naturally jealous of the popularity of philosophers and sophists.

[6] Aristophan. Ran. 1052. [7] Aristophan. Ran. 1111.

From that time, however, a change, introduced by the literary taste of Pisistratus, had gradually prepared the way for establishing a school of philosophy at Athens.[1] Pericles, too, had given a great stimulus to the literary spirit by his own fondness for intellectual pursuits, and the society of intellectual men. In the midst of his active political life, he could find time and thought for the elaborate disquisitions of the ingenious persons whom he invited to him. He could spend a whole day in disputing with Protagoras on so subtile a question as the theory of causation;[2] such was the intense interest which he displayed in every thing tending to the development of mental energy, and such the encouragement he gave to the change of taste then in progress by his own example. In the person of Socrates was found the genius formed to preside over the growing taste for literary and philosophical refinement, and to give it the form of an established institution. What, therefore, were merely indefinite fears at the time of the exhibition of "The Clouds," assumed a more distinct character of alarm to ancient prejudices within a quarter of a century afterwards. The rapidity and violence of several successive revolutions of the government during the latter part of that interval, further prepared the minds of the people for any sudden outbreaks of party spirit, and made every man an object of suspicion to his neighbour. A democracy of an hundred years' existence[3] had been overthrown, and first an oligarchy of four hundred, then a tyranny of thirty, established by foreign arms, in its place. Nor, as it had not been without fraud and bloodshed that the people had been spoiled of their "ancient liberty,"[4] were they disposed to surrender it in quiet; or were those who seized on the government able to retain it long on the same footing. A struggle ensued; in which the individuals of contending parties only sought to provide, each for his own aggrandizement and interest, or at least his own safety, under the constant expectation of some counter-revolution.[5] The people had found that some of those very persons who would never have been suspected of oligarchical views, had in the late changes taken part against the popular government, so that they knew not, at last, whom to trust even of themselves.[6] We are not to wonder that an accusation of Socrates should have succeeded before an Athenian jury at this period of morbid sensitiveness of the public mind.

An accusation of impiety was, we must remember, too, an accusation of a political offence. A change of the popular religion was a change of the fundamental constitution of a Greek state. And as in the absolute rule of a single despot, so in the tyranny of a multitude, the reputation of zeal for religion is studiously maintained from policy, if from no higher motive, to throw around its arbitrary acts the reverence and fear due to the religious character. The teaching of Socrates was indeed eminently religious, but it differed from what the state regarded as such. He proved the existence of an invisible divine power, wisely designing and governing all things, and inculcated the duties of piety and morality as flowing from the belief of such an agency. Such clearly was not the state-religion.[7] This was no system of truth or morality. It was tradition and legend, and immemorial usage, and ritual observance.[8] And it was enough for a charge of impiety that Socrates rested religion on other grounds. A pious Athenian, and yet not pious after the manner of the Athenians, was, in their view, an introducer of new gods. He might well be believed to be a worshipper of the clouds and the air, when he pointed out to them, that the gods would not receive the sacrifice offered by wicked men,[9] that even their silent counsels were not concealed from the divine cognizance, and that justice was an indispensable duty of the worshipper of the gods.[10]

That the accusation further should be credible, as brought in this form, is not strange, when it is known that, during the Peloponnesian war, the worship of new gods had been introduced into the city; as at Rome during the depression of its fortunes in the first years of the second Punic war. So greatly had the vicissitudes of fortune influenced the minds of men, observes Livy, describing this effect,—so great was the influx of religion, and that chiefly foreign, into the state,—that either the men or the gods appeared to have suddenly become different.[11] So at Athens, it appears, the forms of superstition had been multiplied, under the pressure of civil and domestic calamity acting on the fears and credulity of the people. The strong reproof which Euripides puts into the mouth of Theseus, of the austere life of Hippolytus, would seem to point at some ascetic devotees among the Athenians themselves, practising a more refined and scrupulous religion, distinct from that of the vulgar;

> Ἤδη νῦν αὔχει, καὶ δι᾽ ἀψύχου βορᾶς
> Σίτοις καπήλευ, Ορφέα τ᾽ ἄνακτ᾽ ἔχων,
> Βάκχευε, πολλῶν γραμμάτων τιμῶν καπνούς.[12]

In Aristophanes[13] we find still more evident allusion to the introduction of new objects of worship, new fanatical rites, in which the women chiefly officiated, and in which a gross licentiousness mingled with the gloom and solemnities of barbaric superstition.

Again, education was intimately connected with politics in a Grecian state. The state took in hand its youthful citizens, and trained them according to its peculiar institutions, and in its own spirit. At least, in all the early constitutions, great attention was paid to education. Lycurgus made Sparta a constant school of war to his citizens. So too Solon, though he had, with greater knowledge of human nature than Lycurgus, adapted his institutions to the people for whom he legislated, provided that the people should be trained to the system of laws prescribed to them. But this care of the early legislators had begun to be lost sight of in practice.[14] In Aristotle's day it had disappeared everywhere.[15] In Sparta it was still nominally reverenced. In Athens, an entire relaxation of the educational discipline had taken place already in the time of Socrates. Pericles, flattering the democratic spirit of the Athenians of his day, could boast of their ease from labours and the obligation of exercises, and congratulate them on the courage which they could display at the time of action, without being inured beforehand by a course of hardy discipline.[16] But now, whilst the state was remiss in not enforcing education according to its ancient system, a new system had grown up, the offspring of the luxury and refinement of its days of imperial greatness. This new and unauthorized education was diffused throughout the mass of the inhabitants beyond the pale of the citizens. Solon's law imposed the duties of the exercises on the citizens, but excluded the slaves from the gymnasium. Now all classes were hearers of the philosopher; the smith, the carpenter, the fuller, the dresser of leather, were engaged in discussing problems of ethics and politics, no less than the high-born and wealthy citizen, and the orator, and the statesman, and the general. This was an evident indication of a corresponding change in the government itself; a change, which really came to maturity not long after the time of Socrates, when the machinery of the government passed from the hands of the generals and the men of practical ability, into those of the orators of the republic, and when rhetoric, or oratory, became the master science, and only another name for politics.[1]

Those, then, whose attention had been drawn to the person of Socrates many years before, and had then only laughed at the exaggerations of the comic muse, might naturally begin to suspect, in the progress of events at Athens, that there was a real danger to the institutions of the country couched under the humorous mien and conversation of the real Socrates. They would now, as they watched his increasing influence and reputation, recal their early associations of the ludicrous with the name of Socrates, not with the good humour with which they were originally received, but with the undefined fears since acquired, in the course of their daily observation, of one in whose hands the destinies of their country seemed to be placed. They would probably then think that they had judged his case too leniently before as spectators, and that they were now called upon to pronounce authoritatively as judges, not so much from the representations and arguments of the accusers, as from their own experience of the great change which their country had evidently undergone, and was still undergoing. Even indeed at the time of trial, nearly half of the great body of jurors were in favour of his acquittal; and Melitus would have failed altogether, but for the speeches of Anytus and Lycon, men of popular and rhetorical powers, who addressed the court in support of the charge; so strongly did the weight of his personal character, and the interest which he had excited by his friendly and instructive intercourse with every class of citizens, prevail in his favour.

We should take into account, further, the general neutrality of Socrates on questions of politics, and his decisive energy on particular political occasions, in which he was called upon by the circumstances of his position to take part. Both lines of conduct would create enemies. Neutrality in a state distracted with parties is the most unpopular course which can be adopted; however candid and reasonable the principle of such conduct may be, all parties look with jealousy at one who will not be associated with them in the guilt and the danger of party-struggles. They envy him his exemption from their violence, his reputation of candour, his safety under every vicissitude of party-ascendancy. Corcyra, as a state, was obnoxious to the other states of Greece for its neutral policy. So was the individual at Athens who kept aloof from public business, amidst that restless pragmatical spirit which actuated the state and its citizens. Athenians could not understand and appreciate the motives of one who abstained from the public assemblies, and the courts, and the theatres,—who shrank from all public offices,—was a member of no faction or club,—engaged in no trade,—disregarded even his own domestic concerns,—and lived a private man, where every one else was the servant of the public, busy with the affairs of the state, and incessantly pushing his own interests by his political activity.[2] The laws of Solon indeed inculcated the principle, that every one should take his side in the contention of parties.[3] Solon wished to interest the people in the maintenance of the constitution which he had given them; and accordingly, obliged them by penalties to attend to public affairs. This was evidently his reason for compelling their attendance in the assemblies and courts, as also for this singular provision. The increased action of the democratic spirit in the time of Socrates must have greatly fostered the opinion thus declared in their ancient laws. And thus we find philosophers in general held in disrepute at Athens, on account of their inactivity and unconcern in public affairs. The busy sophist, the orator, and the man of the world, censured them as pusillanimous, and indolent, and incapable of the duties of a citizen. Some of the early philosophers, indeed, had been distinguished as statesmen, and legislators, and generals. The Pythagoreans in Magna Græcia appear still to have sustained this character in some measure. But now philosophers were observed, for the most part, to lead a contemplative life of leisure, and to present a striking contrast to the general society of Grecian states. Plato takes every opportunity in his writings of defending philosophy from this calumny directed against the persons of its votaries, evidently treating it as a grievance which he had felt in his own case. Aristotle also indicates the prevalence of the same objection against philosophers at his day, when he studiously maintains that exertions of the mind in mere speculation are to be regarded as even more really practical than those which are directed to external results.[4] Socrates accordingly was a puzzle to many of his contemporaries. They wondered that he should freely dispense the treasures of his wisdom, and not convert it into a marketable commodity. Whilst they gave him credit for integrity, they regarded such a proceeding as mere folly.[5] They asked how he could think to qualify others for public life, without taking part in it himself, if he really knew what it was to be a statesman. But he was content, in reply, to point to the number whom he had laboured to render capable of public duties, as a more effectual service on his part to the state, than a mere personal activity.

But though the general conduct of Socrates was to avoid all interference in affairs of state, he had shewn on one or two very important occasions his patriotic feeling, and the energy with which he could carry it into effect. He had served with distinguished courage at Potidæa, Amphipolis, and Delium, as we have seen; and proved himself, on those hard-fought days, one who, as Pericles characterizes the Athenians, could philosophize without effeminacy, and, without being inured to the dangers of the field, could brave them at the moment of trial with no diminished spirit. But still greater occasions of trial were those of civil exertion at home, to which he was called not long before the accusation of impiety. Perhaps one of the most memorable instances of resolute firmness which history presents, is to be observed in the fact, that when the uproar of faction was demanding the iniquitous condemnation of the generals who commanded at Arginusæ, Socrates stood alone among his colleagues in office, and refused to put the question to the vote, as the epistates, or superintendent of the day, in the form proposed.[1] Each of the ten Athenian tribes had its turn of presidency in the council of Five Hundred for thirty-six days of the year; fifty out of the whole tribe being chosen by lot as its representatives during this period. These fifty were further subdivided into tens; and each of these tens, under the name of proëdri, served a week in succession, as it was allotted, until the official term of the tribe was completed. Again, of these ten presidents, seven were appointed by lot, to occupy the chair in succession during their week of office; each one of the seven becoming in his turn epistates, or superintendent for a day. The tribe Antiochis, to which Socrates belonged, happened to be the presiding tribe on the occasion of the impeachment of the generals; and it came to the lot of Socrates to be in the chair of office on the day when the question of their condemnation was so passionately debated. The generals had nobly done their duty to their country, and gained the most brilliant victory which had been achieved at sea in the course of the war by the Athenian arms. But the crisis was an unfortunate one for them. Athens was then on the verge of ruin. The jealousy of parties was at its height. The hopelessness of recovering the lost ground by military strength at this time, gave an opening and encouragement to personal intrigue, and the arts of an unscrupulous diplomacy; and a victory, however honourable to their arms, and hopeful as to the future, seems only to have been hailed with very doubtful congratulations by the struggling factions of the city; each looking at it rather as it might act for or against his party,—as it might tend to the strength of his rivals or their depression,—than as a great public triumph. However this may be, for the event remains a matter of perplexity to the historian, the successful generals were brought to trial through the treachery of their own officers, on the specious charge of having neglected the collecting of the dead bodies of their men after the action.[2] The charge was specious, because it was partly true, and was attested indeed by the very officers who were sent by them on that service, and who were now brought as witnesses against their commanders. It was true, so far as the endeavour to collect the dead bodies had been frustrated by a violent storm which followed the engagement. Still the endeavour had been made. The charge was further specious, because it appealed to religious prejudices, as well as to the democratic spirit. The generals seemed to have been regardless of the solemn rites due to the dead, and of the persons and feelings of the lower orders of the people. The occasion therefore furnished abundant topic of invective to the demagogues; and their addresses too fatally succeeded in obtaining an ungrateful and factious vote of death against the generals. Socrates was threatened with criminal information by the orators of the people; and the people themselves were urging on his assailants, and clamouring against him. Still he remained unmoved, and would not put the unjust question to the vote; preferring the hazard of bonds and death to himself, on the side of the law and right, to a compliance with the popular will in an illegal act.[3] The iniquity was perpetrated ultimately in spite of his resistance; but he at least did his utmost to prevent it.

Such was his conduct under the ascendancy of the democratic power. Afterwards, when the oligarchy was established, and the Thirty were exercising their acts of cruelty and extortion without restraint, he was the first to give a check to their tyranny. In their career of confiscation and blood, they marked out Leon of Salamis for destruction. They conceived that the terror of their power would compel even Socrates to be a ready instrument to their rapacity; and they were desirous also doubtless to implicate him in the criminality of the act. Accordingly, they appointed him with four others to go to Salamis, and bring Leon to Athens, that he might be put to death. They were disappointed, however, in their expectation, so far as they depended on Socrates as an instrument in the dark deed. The order was executed, and the unhappy Leon was sacrificed to their cruel avarice and fears. But Socrates had no hand in it, and resisted it as far as he could. Unawed by their stern command, he said nothing, but as soon as he had left the Tholus, the place where the Thirty were assembled, he left his four colleagues to proceed on their bloody errand and went home. He would not, indeed, have dared thus to disobey the order with impunity; he would surely have felt their vengeance;—for there is nothing that tyrants resent more than a clemency volunteered by the ministers of their cruelties,[4]—but that happily that reign of terror was soon after put down.

By these intrepid acts, Socrates had shewn that the philosopher, in declining the contentions of political life, did not incapacitate himself for his duties when the exigencies of his situation should require him to perform them.[5] As Thales had proved that the philosopher could, if he pleased, make money, by applying to that purpose his observations on the seasons, and his prognostics of an abundant crop of olives;[6] so did Socrates defend philosophy in his own person, and by his conduct on these great occasions, against the imputation of inactivity and selfish ease. It is quite evident, too, that such a spirit as that displayed in these remarkable instances, had he entered into political life, would have subjected him to violent collisions with the successive leaders of party at Athens. "You well know, Athenians," are the words which Plato's "Apology" puts into his mouth, "that had I long ago attempted to take part in political affairs, I should long ago have perished, and I should neither have done you any service nor myself. And be not aggrieved with me for saying the truth. For there is no one of men that can be safe, in giving a spirited opposition either to you or to any other popular government, and in preventing the occurrence of many unjust and iniquitous things in the state; but he that would in reality fight for the right, must, if he would be safe but a little while, lead a private life and not engage in public business."[7] "Think you, indeed," he further asks, "that I should have lived for so many years, had I engaged in public business; and had I, engaging in it in a manner becoming a good man, succoured the cause of right, and, as behoved me, made that the thing of greatest consequence? Far from it; for neither could any one individual of men."[8]

The time, then, appears to have arrived, when the accusation was brought by Melitus, for his exemplification of the truth of this observation in his own person. He had hitherto avoided the impending storm by the quiet tenour of his private life. But he had done enough to offend the partizans of either extreme in the state. Both extremes would be united against him in their enmity to all moderation; for the ascendancy of such counsels as his, would have been a death-blow to their own reckless lust of power. Hence, they were readily disposed to concur in sacrificing him to their mutual resentments. And we thus behold the sad spectacle of one who had been the friend of every poor man at Athens, no less than of the rich and noble, requited with prosecution and death by those very hands conjoined in the unnatural act, which each should have warded off the blow inflicted by the other. The genius of Intolerance was indeed behind the scene, mixing the poisoned cup for its destined victim. But the actors on the public stage of the trial were, at the same time, wreaking their own vengeance on a political opponent; and the more exasperated against him, in proportion as, by his imperturbable demeanour and real inoffensiveness, he seemed to defy their assaults, and to throw them back on the consciousness of their injustice and ingratitude towards him.

[7] Plato, Apol. 31, 32.

[8] Ibid.

Nor can there be any doubt, that there were many individuals, whose pride he had hurt, whose ignorance he had exposed, whose ill-humour he had irritated, and who, such is the infirmity of human nature, would rejoice in the opportunity of revenge by the verdict of a public condemnation of his doctrine. In affronting the sophists by his free discussions of their pretensions, he had excited, doubtless, the hostility of many of the higher order of citizens, their patrons and disciples. Many fathers of families too must then have been suffering from that corruption of public morals which, under the teaching of the sophists, had clothed itself with plausibilities of argument, and impudently arrogated, for its vain pretensions, the importance of philosophy. Disobedient, profligate sons, lifting their hands against their fathers, and adding bitterness to their unnatural rebellion, by the hollow false-hearted principles upon which they had learned to justify it,—forward, petulant youths, insulting the dignity of age by their pretensions to superior wisdom, and their turbulence,—these were the fruits of sophistical education, which came home to every family at Athens. Few that felt the evil in their own homes, would stop to inquire whether Socrates was the teacher whom they had to blame for their suffering. Most would hastily conclude, that all such instruction of the young was pernicious, and their offence at the mischievous doctrine of the sophists would become a disgust to philosophy and philosophers.

Some, indeed, would distinctly trace to Socrates the annoyance which they had experienced from particular individuals. There were many who had frequented the society of Socrates, with no sincere intention of profiting by his lessons,—who observed his inquisitive manner, and its effect in convicting and refuting the errors of those with whom he conversed, and who endeavoured, for their own wanton gratification, to imitate him in their intercourse with others. These would take delight in confounding and perplexing others, and exposing and ridiculing their pretensions to wisdom. It is easy to conceive, that the superficial resemblance to the manner of Socrates in these persons, and the vexation produced by it, would excite angry objection against the real method of Socrates.[1] These persons would be pointed at as his disciples. These would be referred to as instances of the evil tendency of the teaching of the philosopher himself; the discredit of the spurious disciples being reflected on the master, to whom it belonged not in any degree.

It appears, further, as might have been expected, that the doctrines of Socrates were studiously misrepresented at the time. Allusions or illustrations employed by him in his reasonings were construed into positive opinions on the subjects to which he thus referred. For example, when, inculcating honest industry, he quoted Hesiod,[2] saying, "Work there is none that is a scandal, inaction is the scandal," the captious absurdly but maliciously interpreted him, as applying the words of the poet to sanction the doing every thing, whether right or wrong, for the sake of gain. When he quoted from Homer the account of Ulysses silencing the uproar of the people, against the practice of employing worthless persons in the public service, it was represented, that he approved the coercing the common people and the poor by harshness and violence.[3] Again, in urging the necessity of looking to the qualification of those who should be appointed to office, and illustrating this by the fact, that no one would choose, by lot, a pilot, or carpenter, or flute-player, or any one, indeed, in matters where error was far less mischievous than in politics,—he was charged with encouraging contempt of the established laws, and exciting the young to acts of violence.[4] And, (which is the most invidious form of misrepresentation), a general charge of corrupting the young was thrown out against him, unsupported by any specific statements of the means of corruption which he employed. As in the polemics of later days, so in the controversy between Socrates and his assailants, the obloquy of general hackneyed terms of reproach was resorted to as the substitute for definite grounds of imputation. Thus were the off-hand allegations against all philosophers,—"that they searched into the things in the air and the things under the earth, and rejected all belief in the gods, and made the worse appear the better reason,"[5]—used as a cover, on this occasion, to the envy and malignity which shrank from the light and the evidence of facts.

The accusation of Melitus, it will be observed, was distributed into three heads: 1. Contempt of the established religion. 2. The introduction of new divinities.[6] 3. The corruption of the young. The second of these charges requires to be more particularly noticed, because it has reference to a peculiarity in the conduct of Socrates which gave it a colour of truth.

The mind of Socrates appears to have been deeply imbued with religious feeling. The observation of final causes particularly excited his interest; so much so, as to lead him to think that no other account should be attempted to be given of the phenomena of the world, but as they are the results of a wise and benevolent design. He delighted thus in contemplating every thing in a moral and religious point of view. He thought that the introduction of physical and mechanical causes into the study of nature, only perplexed and misled the mind. He had at first been greatly attracted by the speculations of Anaxagoras. What won his attention in the system of this philosopher, was its distinguished merit beyond all previous systems, in assigning mind as the master principle of the universe. But when he came to study the writings of Anaxagoras more closely, he was grievously disappointed, and threw up the system in disgust. For he found that it lost sight of the grand and true principle with which it set out, and, after all, constructed the universe out of mere material and mechanical elements.[7]

---

[1] Xenophon speaks of persons who were pointedly corrected by Socrates, *μὴ μόνον ἃ ἐκεῖνος κολαστηρίου ἕνεκα τοὺς πάντ' οἰομένους εἰδέναι ἐρωτῶν ἤλεγχεν.* Mem. i. 4. Such persons would bear a grudge against him, as Anytus in particular appears to have done, and would not be very scrupulous, with this angry feeling dwelling in their minds, as to the mode of resenting the affront.

[4] Plato, Euthyphro, 3, 6. *ὥστ οὖν καινοτομοῦντος σοῦ περὶ τὰ θεῖα, γέγραπται ταύτην τὴν γραφήν· καὶ ὡς διαβαλῶν δὴ ἔρχεται εἰς τὸ δικαστήριον, εἰδως ὅτι ευδιάβολα τὰ τοιαῦτα πρὸς τοὺς πολλούς.* Op. i. p. 6.—Xenoph. Mem. i. 2, 9.

[5] Plat. Apol. 23, p. 54.

[6] Athenians preserved the same character at the time of St. Paul in this respect, also, as well in their eagerness after news; as is seen in their accusing him of setting forth strange gods. (Acts xvii. 18.) *ξένων δαιμονίων δοκεῖ καταγγελεὺς εἶναι.*

[7] Plato, Phædo.—Apolog.

He saw, indeed, how futile, as to any real knowledge of the universe, had been the inquiries of the early philosophers. As an Athenian, he participated in that general prejudice against physical science, which Athenians had ignorantly imbibed against all philosophy, when they characterized it as idle talk and drivelling dotage. But as a genuine philosopher, in spite of his Athenian prejudices, he saw and felt that there was a real moral agency pervading the world; and he judged that, by observation of this, principles of real use for the right direction of human life might be discovered. Tinctured too, as an Athenian, with the superstition of his countrymen, and at the same time correcting it by his superior judgment and feeling, he was disposed to draw every phenomenon into his moral and religious theory of the universe. To stop to inquire into any thing whether it might be explained on simple natural causes, or to doubt its moral design, would appear to his mind as sceptical and profane. Hence, we see at once displayed in him the common character of the Athenian, in his dislike of physical science, and his susceptibility of superstitious influences from the most trivial things; and, on the other hand, the wisdom and religiousness of the true philosopher, in his constant devout disposition to refer all things to a providential design and moral agency.

It is well known how anxiously the heathens watched the most minute circumstances, not only in their religious rites, but in the actions of daily life, as intimations of the will of the gods. Not only dreams and visions, but flights of birds, the meeting any particular object, sneezing, a voice, or any sound, and the like trivial things, were regarded with seriousness and awe. Socrates felt the mystic influence of such incidents; only he thought more deeply on them than the generality, and that,—not with the vulgar emotions of fear or of hope, according as the omen might be interpreted,—but with calm and pious reference to the benevolent design which he attributed to them as divine intimations. Further, not only did he apply this sentiment to the outward circumstances of daily life; but he also took into his view the state of his own mind. He conceived that he received at times mysterious signs distinctly perceptible to himself, not indeed of any positive good to be expected from a particular course of conduct, but of precaution,—warnings against evil concerning others as well as himself. These presages he interpreted,—or others perhaps, taking his account of his impressions in too literal a manner, have so represented it,—as a voice addressed to him on each occasion. Instances too, are alleged in which this divine voice was the means of saving him and those who obeyed its direction, from danger. In the retreat of the Athenians after the unfortunate battle at Delium, it is said to have prevented his taking a particular road, and thus saved him, together with Alcibiades and Laches, from being pursued and overtaken by the enemy; whilst others taking another way were overtaken and slain.[1] This circumstance, according to Plutarch, was a great occasion of the fame at Athens of the "demonion,"—or "genius," as it was called by Latin writers,—of Socrates.[2] To this voice is attributed his active devotion of his life to the moral reform of his countrymen by private and personal addresses to them, and his refraining at the same time from all political exertion.

The name of a particular dæmonion, or genius, was evidently not assigned by Socrates himself to these extraordinary presages, while he confidently declared their reality. It was rather the misconstruction of the vulgar, and of his assailants, interpreting what he affirmed generally of divine intimations, as assertions of the presence of some particular divinity ascertained by his own convictions, and distinct from the gods worshipped at Athens. Heathens were incapable of forming a notion of the Deity, but as a local and tutelary god. They could not rise to the sublime conception of the one universal Being, *τὸ δαιμόνιον*, the God in all the world, than whom there is none else. In the view of Socrates, this belief in a presaging voice addressed to his private ear, was nothing more than an extension of the prophetic science, or divination of the heathen world, to practical purposes, and to the cultivation of religious feelings.

It must be remembered, that the Athenians had their augurs or prophets among the regular officers of the republic, without whose presence no matter of public counsel or of war was ever transacted. These were the recognized interpreters of the divine will. But Socrates claimed a special authority for the presages with which he was peculiarly favoured, and thus seemed to innovate on the science, and encroach on the established forms, of divination. He enjoined, indeed, a devout reference to the Delphic oracle, in all questions of hazardous conduct, teaching that, whilst human reason was the guide in all matters of human power, in those, on the contrary, which were out of human power, as the future event of actions, resort should be had to every means offered for exploring the will of the gods. He professed to have adopted his own course of life on the evidence of such communications. He advised Xenophon to consult the Delphic oracle, as to whether he should do well in accepting the invitation of Proxenus to join the expedition of Cyrus.[3] But with this reverence for the recognized sources of divine information, he combined a suspicion of the pretenders to prophecy, who were countenanced by the popular superstition,—the *θεομάντεις* and *χρησμωδοι*,—who abounded at Athens.[4] He relied rather on the sagacious auguries of his own mind, drawn from observation of some passing incident, or some rapid conclusion respecting the consequences of actions—a kind of intuitive judgment and forecaste, mingling and confounding itself with his religious impressions,—a second hearing, as it were,—a perception of a voice unperceived by the common ear, mysteriously telling of danger to come from some particular course of conduct. Thus was a pretext given to his enemies to say, that he introduced "new divinities;" whilst public opinion tolerated the grossest pretensions to divine revelations, and a system of mercenary imposture founded on them. Public opinion upheld the system of divination as it existed, with its external array of augurs, and prophets, and ceremonial. Socrates, on the contrary, led every man to consult the will of the Deity, not without devout preparation in the inward recesses of his own mind, nor without reference to his own obedience and moral improvement.[5] Superstition, doubtless, strongly tinctured his notions of religious duty. This made him construe many things into divine intimations, which were frivolous and irrelevant. Still he rose above the superstition of the popular divination, in the personal piety which laid hold of each occasion for its exercise and cultivation, and taught men to regard the Divinity as interested in the protection of the good, and ever present to the words, and actions, and even the silent thoughts of men.[6]

Xenophon appears to have faithfully stated the difference between the popular divination and that professed by Socrates, in the following account: "He introduced nothing new beyond others who, acknowledging the reality of divination, make use of omens, and voices, and objects presented on the way, and sacrifices. For these do not conceive, that the birds, and the persons that meet them, know what is expedient to those who divine by them, but that the gods, by means of them, signify this. And so he held. But the generality say, that they are dissuaded and persuaded by the birds, and the objects that meet them; whereas Socrates spoke of it as he thought. For he said that it was the Divinity, *τὸ δαιμόνιον*, that gave signs to him. And to many of his intimates he prescribed to do some things,[1] to forbear other things, on the ground, that the Divinity had presignified it to him; and it was to the advantage of those who took his advice, whilst those who rejected his advice had to repent it."[2]

[5] Plato, Alcib. ii. 150, p. 99. *Καὶ γὰρ δεινὸν εἴη, ἐι προς τὰ δῶρα και θυσιας ἀποβλέπουσιν ἡμῶν ὁι θεοὶ, ἀλλὰ μὴ πρὸς τὴν ψυχὴν, ἂν τις ὅσιος καὶ δίκαιος, κ. τ. λ.*

[6] Xen. Mem. i. 1, 19. *Καὶ γὰρ ἐπιμελεῖσθαι θεοὺς ἐνόμιζεν ἀνθρώπων, ὀυχ ὃν τρόπον οἵ πολλὸι νομιζουσιν, κ.τ.λ.*

But how great was the change from the practical devotion of the mind here taught by Socrates, from that popularly entertained at Athens! The history of divination, as it was regarded, not at Athens only, but throughout Greece, is but a picture of the invidiousness and malignity of the human heart transformed into attributes of the Divine Being. Let us only hear Solon, as he is described by Herodotus, speaking of the Deity as a principle of envy and turbulence, and as guided by no fixed course in the disposition of human affairs; and we may judge what a task he had enterprized, who entered into conflict with this inward and subtile idolatry of human passions, established by the heathen system of divination. It was indeed teaching divinities new to Athenian ears, when Socrates inculcated an inward reformation of the character of those who would look for the favour of the gods, or expect a special interposition and direction from the benevolent principle which guided the course of the moral world.

Whereas, too, the popular divination was employed on the most trivial occasions, and made the substitute for the proper exertion of men's faculties on matters cognizable by them, Socrates differed from this prevalent notion of the subject. He contended, that, where the line of conduct was plain, men should use the best of their judgment in acting,—that they should use their experience and reason in learning what the gods had given them to learn by such means, and only have resort to consultation of the Divine will by the extraordinary means of divination, where the results of conduct were uncertain. Thus might he be construed as dissuading men from the use of divination, when he only dissuaded from an improper use of it, and exhorted to a rational activity.

We may see from the story of Aristodicus of Cyme, how the practice existed among the Greeks, of endeavouring to obtain from the oracles sanctions even to iniquities and impieties. Aristodicus consults the oracle whether he may surrender an unhappy fugitive; and the oracle permits him, dexterously reproving, by the very permission, the attempt to cast the burthen of personal responsibility on the oracle itself, and to cover an immoral act with the veil of religious duty.[3] Divination, in fact, was indolently resorted to in the heathen world, to relieve the mind of the labour and anxiety of thought, and the searchings of conscience. And Socrates addressed himself to the correction of this practice, by recommending, as we have seen, exertion of the judgment, and the acquisition of information on all matters within the sphere of human reason. He would thus provoke the hostility of many a professed diviner, who made a trade of his art, and would find individuals of this class ready to join in the outcry raised against him, of innovation on the popular theology.

The jealousy of the sophists in particular, the very class with whom the accusation of Melitus identified him, would also swell the popular envy against him on this head. For the sophists, among their pretensions, claimed to be regarded as endued with a predictive sagacity, so as to be expert practical guides respecting the future.[4] Socrates would offend them in this point in two ways,—both as directing persons to have recourse to their own judgment, and the regular means of information on all ordinary questions to which human reason was competent; and as teaching a reference to a secret divine intimation on all other matters beyond the compass of man's understanding. For in both respects would the sophists find their course interfered with. The use of men's own judgment, or the appeal to the signs of the Divine will, would equally lessen the value for those counsels which they pretended to impart.

What added still further to this invidious feeling was, that the reputation of Socrates now eclipsed theirs throughout Greece. And Socrates appears himself confidently to have appealed to this public estimation of his character against the partial censures of his countrymen at the time of his trial. He vindicated his assertion of divine intimations specially granted to him, by referring to the oracle of Delphi as having honoured him with its distinct approbation. Chærephon, in the devoutness of his admiration of his master, had, on some occasion, consulted the oracle respecting him, and obtained an answer that Socrates was the wisest of men. The authenticity of the anecdote has been questioned. But the introduction of it in the two "Apologies,"[5] may be taken as a voucher of its substantial truth. It at any rate shews the favourable opinion which had been conceived of him out of Athens itself; that, as Lycurgus had been complimented by the verdict of an oracle, so the same tribute of public applause might, with equal probability, be assigned to Socrates.

According to Laertius, the sentence of condemnation was carried by a majority consisting of 281 votes. The number was little more than sufficient to decide the question on that side; for it only exceeded the number of votes of acquittal by three. "Had but three votes only fallen differently," says Socrates himself, in the "Apology" of Plato, "I should have been acquitted." Nor, indeed, would Melitus alone, without the aid of Anytus and Lycon, (he is made there confidently to declare) have obtained even a fifth part of the votes to save him the penalty of a thousand drachmas, affixed by the law to an unsustained prosecution. But when the penalty of death was further put to the vote, and he was found unwilling to propose the substitution of any other penalty, such as a fine or exile, but evinced his indignant contempt of their unjust sentence, by asking rather, in his ironical way, instead of even a slight punishment, the highest honour of the state, that of a public maintenance in the Prytaneum, the multitude of the jurors was so exasperated by the unbending spirit thus displayed, that eighty additional votes were given on the hostile side, determining the sentence of death. So evidently was the whole case ruled by passion and the arts of demagogues exciting the people to treat it as a slight on their majesty, rather than as a cause in a court of justice. Otherwise it could not have happened, that when the previous question of guilt had been carried with nearly an equal number of dissentients, the severest penalty should have obtained such an accession of voices in its favour.

We have already remarked the little solicitude shewn by

---

[1] Xenophon here differs from Plato's Apology, in saying, that Socrates received intimations of what was to be done; whereas Plato expressly says the directions were only negative.

Socrates in regard to his defence from the accusation. As he strongly disapproved the affected artificial rhetoric of his times, and the practice of appealing to the passions against the judgment of the hearer, so neither would he study beforehand what he should say on the occasion of his trial. Twice had he essayed (he observes to Hermogenes) to consider what he should say in his defence, and as often had he been prevented by those secret divine intimations to which he habitually referred his conduct.[1] Nor again would he receive the proferred services of friends in pleading his cause. The celebrated orator Lysias composed an oration for this purpose. On reading it, he expressed his admiration of it, but declined it as unsuitable to him. When Lysias wondered that he could admire it, and yet say it was unsuitable, he observed, in his usual manner of illustration, by an apposite case; "Would not also fine coats and shoes be unsuitable to me?" Plato, however, it is said, could not be restrained from appearing in his behalf, and made an effort to address the court. But the uproar was so great, that on his uttering the words, "ascend the bema," he was met with the cry, "descend," and forced to abandon the attempt.[2]

So neither, again, would he resort to those appliances to the feelings which were usual in the Athenian courts. The Athenian juryman expected that the defendant should come before him in the character of a suppliant, and entreat his clemency rather than claim his justice. He was to be assailed with prayers and tears, no less than with arguments addressed to his understanding. But Socrates would not condescend to these methods of persuasion. He would not produce his wife and children in the court, to excite compassion, or bring forward his connexions and friends to intercede in his behalf. He felt it unbecoming in him at his age, and with his reputation as a philosopher, to supplicate for his life. It would have given to his whole previous demeanour the appearance of insincerity and hypocrisy. It would have shewn that dread of death, against which all his teaching had been directed.[3] It would have been an evidence that he disregarded the sanctity of religion, in trying to influence his jurors to decide by favour against their oaths, and so far would have substantiated the charge of Melitus against him.[4] For the same reason, he had refused to offer to submit to a mitigated penalty, when challenged, according to the practice in the Athenian courts, to propose his own estimate of the offence. Afterwards, indeed, he softened this bold vindication of his merits, by adding, in the same ironical manner, that he could perhaps pay the fine of a mina of silver, and would therefore fix that amount of damages; or that as Plato, Crito, Critobulus, and Apollodorus, suggested the sum of thirty minæ, and would be good sureties for the payment, he would fix the latter amount.[5] To have seriously proposed any such estimate would, in his opinion, have been an admission of his guilt.[6]

He displayed throughout the trial, the same calm and cheerful temper which characterized his ordinary behaviour. There were in his manner, even at that solemn crisis, touches of the same ironical humour, the same half-earnest, half-playful strokes of argumentative attack, which had given so much interest and point to his daily familiar conversations; and when the trial was over, he evinced no further emotion than the indignation of a sincere and honest man. at the malicious and mischievous arts by which the result had been accomplished. He was sustained by the consciousness that no crime had been proved against him; whilst his assailants must feel the reproaches of conscience for the real impiety and iniquity of which they had been guilty; some for having instigated others to bear false witness against him; some for having themselves borne this false witness. The disgrace of the condemnation fell not on him, he asserted, but on those who had passed such a sentence. He consoled himself with the thought, that it was the will of the Deity, and it was best for him now to die; that, though condemned by his present judges, like another Palamedes, he should receive from posterity that verdict of approbation which was withheld from Ulysses, to whose successful plot the life of that chief was sacrificed.[7] Availing himself also of the prophetic power which the popular belief attributed to the words of a dying man, he warned his countrymen, as he left the court, that they were embarked in a course which must involve them in bitter repentance.[8] He concluded his address with the following striking admonition: "I have only this request to make. As for my sons, when they shall have grown up, punish them, I pray you, by troubling them in the same manner in which I have been in the habit of troubling you, if they appear to you to concern themselves either with money or any thing else in preference to virtue. And if they would seem to be something when they are nothing, reproach them as I do you, that they take no concern about what they ought, and think themselves to be something when they are nothing. And if you do this, I shall have suffered justice at your hands, both myself and my sons. But it is now time to depart; for me to die, for you to live; but which of us is going to a better thing is uncertain to every one except only the Deity."[9]

In his way from the court to the prison to which he was now consigned, he was observed with eye and mien and step composed, in perfect unison with his previous address. On perceiving some of those who accompanied him, weeping, "Why is this," he said; "is it now that you weep? did you not long ago know, that, from the moment of my birth, the sentence of death had been decreed against me by nature? If, indeed, I were perishing beforehand in the midst of blessings flowing in upon me, it would be plain that I and my kind friends would have to grieve; but if I terminate my life at a time when troubles are expected, for my part I think you ought all to be in good heart, as feeling that I am happy."[10] Apollodorus, whose admiration of his master amounted to an amiable weakness, complained to him of the great hardship of his suffering by an unjust sentence. Acknowledging the affectionate feeling thus shewn to him in a familiar manner, by passing his hand over the head of his attached disciple, he, at the same time, gently reproved him, saying, "Would you then, my dear Apollodorus, rather see me dying justly than unjustly?" and smiled at the question. On seeing Anytus pass by, he could not forbear, it is said, the expression of a strong censure on the conduct of that individual towards his own son. He foretold, what the unhappy result proved too true, that the heart of Anytus would one day be embittered by the evil fruits of that low and unworthy education to which, with mercenary views, he had subjected his son, a young man with whom the philosopher had formerly conversed, and who had seemed destined for better things.

The execution of Socrates, by the poisoned cup, would have followed immediately on his condemnation, but for the peculiar circumstances under which the trial had taken place. It was after the commencement of the Delian festival; an annual commemoration, of the safe return of Theseus and his devoted companions to Athens, from the fatal labyrinth of Crete, and the acquittal thenceforth of the bloody tribute exacted by Minos, by the mission of a vessel to Delos with sacrifices to Apollo, and other religious rites. When the priest of Apollo had once crowned the stern of the sacred vessel with the festive garland, it was not lawful to pollute the city by a public execution, until the solemn pomp should have been performed, and the vessel had returned. This ceremony had been performed only the day before the trial of Socrates. Thus he obtained the respite of thirty days between his trial and execution.

[10] Xenoph. Apol. 27.

These were days of high interest and importance not only to his sorrowing friends, but to the cause of that admirable practical philosophy which all his previous life had inculcated. During this time he employed himself in literary exercises which he had never practised before. He composed a poem in honour of the god Apollo, whose festival was then in course of celebration. And feeling a religious scruple as to whether by the general pursuit of philosophy, he had fully complied with the suggestions of dreams repeatedly urging him, as he said, to "cultivate music," he now applied himself to the fulfilment of this supposed charge, by turning the fables of Æsop into verse.[1] But these were only pastimes illustrative of the serenity of his mind. Now, too, in his prison, with the chains on his body, and the near prospect of a violent death, he could discourse with an unanswerable cogency and eloquence of argument, of the vanity of human things, and the real happiness of man, as consisting in the cultivation of the spiritual and immortal principles of his nature. He had professed his whole life to be a meditation or discipline of death. He now had the opportunity,—which, as a philosopher, (could the voice of natural instinct have been silenced,) he would most have desired,—of realizing, by his own example, that death to which his thoughts and pursuits had been studiously directed. Unlike his successors in the schools of the Stoics, he did not advocate a doctrine of suicide, however he depreciated the importance of human life. With that good sense which restrained his religion and his philosophy from running into fanaticism, he held it to be impious in any one to release himself, by his own hand, from that post of duty in which the Deity had placed him.[2] Though, however, he had not courted death, or rashly placed himself in the way of it, he felt that, in the circumstances in which he was now placed, he was called to go through this last act of his philosophic profession. He seems, indeed, to have rejoiced in the opportunity thus afforded him of summing up his philosophy in one great principle, from which every observation and argument, in the course of previous teaching, had been drawn, by demonstrating, so far as reason could avail to demonstrate the fact, the absolute and eternal existence of the great principles of moral truth. The occasion was one which the genius of Plato would not fail to seize as most felicitous for the development of its own enthusiastic and transcendental view of the philosophy of Socrates. Plato, accordingly, has, in that most exquisite of his Dialogues, the Phædo, invited us to the couch of Socrates, on the last sad morning of his imprisonment, to listen to the philosopher, with the chill of death almost upon him, discoursing on the immortality of the soul. The affectionate and eloquent disciple doubtless shed natural tears over his dying master. But he wished also to elevate his own philosophy to the dignity of being the dying confession of the great sage of Athens. And he wished, further, that his own philosophy should speak, as it were, the funeral oration over him to whom it was indebted for its earliest inspirations, and pour its own libation on his tomb. Thus he has especially elaborated the last scene of his master's life, and made us contemplate with the deepest interest the death of Socrates, not only as an act of heroic self-devotion and patient martyrdom to the truth, taught by the great sage himself, but as a splendid episode in the dramatic development of his own philosophy.

During his imprisonment, Socrates was not denied the solace of receiving his friends, and conversing with them day after day. Early each morning might be seen a company of devoted friends, whom nothing could separate from him, assembled at the hall of justice, where the trial had taken place, and which was close to the prison, watching for the jailor to open the gate and admit them. Being admitted, they would commonly remain with him in the prison until evening, engaged in earnest and instructive conversation. His wife and children, too, appear to have been constantly with him.[3] He was importuned by these affectionate followers to suffer them to effect his escape. Crito earnestly entreated him to be allowed to execute a plan which he had concerted for rescuing him. Simmias, the Theban, also brought a sum of money with him to Athens for that purpose. Cebes and others were equally ready with their resources. They argued, that, so far from being at a loss what to do with himself out of Athens, as he had said on his trial, they could ensure him friends in Thessaly, and many other places, who would most gladly welcome him, and protect him. But to none of these importunities would he yield. He answered, that, while he highly estimated their kindness, he was pledged to obey reason only, and that he saw no ground in his present circumstances for taking a different view of his case. As for the duty of providing for his children, by preserving his own life,—a consideration which Crito appears to have strongly pressed on him,—this was not now a matter for him to consider;—it was for those to consider, who, as his Athenian judges, treated life and death as such light concerns; for his part, he must look simply to what was right or wrong to be done.[4] Thus steadily and calmly did he persevere in his resolution of awaiting the utmost extremity.

At length it was announced that the Theoric galley had been seen off Sunium, and might very shortly be expected to arrive at Athens. Crito proceeded in anxious haste to the prison, and being well-known to the jailor from his frequent visits there, obtained admission at a very early hour. He found Socrates asleep, and sat by him in silence, wondering to see him sleep so soundly in so much trouble, until he at length awoke to receive the fatal intelligence. This he received with the same composure as if it had been some ordinary communication. His only answer to Crito was, that he was quite resigned to the will of the gods, if it were so, but that he was persuaded by a dream, from which he had just waked, that the vessel would not come that day, but the following one. His reliance on dreams as divine intimations, has been already mentioned. He told Crito, accordingly, of his having dreamed that a woman of noble form, clothed in white, came to him and called him, and said to him in the words of Homer,[5] "On the third day to deep-soiled Pthia thou shalt come." The event, at any rate, accorded with his expectation from the dream. On the morrow the vessel reached the harbour of Piræus; and the following day was appointed for the execution.

By the dawn of that day, the sorrowing party again met at the accustomed place, and were informed by the jailor, that the Eleven,—the officers who superintended the public executions,—had given orders that the chains should be taken off, and that Socrates should die on that day. After being kept waiting some time, they went in and found the philosopher already loosed from his chains, and sitting on the couch, with Xanthippe and his youngest child in her arms, by his side. By his desire they conduct her home, the kind Crito entrusting her to the care of his attendants, amidst cries of passionate grief, which had broken forth from her afresh at the sight of them now come to bid their last farewell. The occasion naturally leads to the conversation which follows a discussion, according to Plato, on the immortality of the soul,—Socrates interrogating and arguing with all his wonted vivacity; whilst the party around him answer and listen with eager interest, and, as may naturally be conceived, with undescribable sensations of mingled delight and pain. Crito would have dissuaded him from this exertion, for he feared, from what he had been told by the executioner, that the heat of the body thus produced, would add to his discomfort in his last moments, by rendering the effects of the poison more lingering. He only observed, that "it mattered not; the executioner should only be ready to do his duty, and mix the draught twice, or even thrice over, if it should be found necessary."[1]

[5] Ἤματί κεν τριτάτῳ Φθίην ἐρίβωλον ἵκοιο.

The discourse being brought to a close, he rose to proceed to the bath, as an immediate preparation for his death; when Crito detained him for a while, to ask his last commands about his children, or any other matter in which their services might gratify him. He replied, "that he had nothing new to say beyond what he had ever been saying,—that by attending to themselves, they would most gratify him and his, as well as themselves, in all they might do, though they might even make no promise now; but that if they neglected themselves, and were unwilling to follow in the track pointed out in all that he had said to them up to this last occasion, all that they could do would be of no avail, however much, and however earnestly, they might promise at the present moment."[2] Crito assented to this advice, but in his eagerness still to do some act of kindness to his revered friend, subjoined, "But in what way are we to bury you?" This mode of speaking of his burial, gives occasion to a very characteristic reproof from him, of this solicitude on the part of Crito. "As you please," was his answer, "if at least you can take me, and I do not escape from you." Then gently smiling, and looking off to the surrounding company, he added, "I cannot, my friends, persuade Crito, that I am the Socrates that is now conversing, and ordering every thing that has been said; but he thinks that I am that man whom he will shortly see a corpse, and asks how you should bury me. But what I have all along been talking so much about,—that when I shall have drunk the poison, I shall no longer stay with you, but shall, forsooth, go away to certain felicities of the blest,—this I seem to myself to have been saying in vain, whilst comforting at the same time you and myself. Bail me therefore, to Crito the opposite bail to that which he bailed me to the judges; for he was bail for my staying; but do you be bail for my *not* staying when dead, but going away; that Crito may bear it more easily, and may not feel aggrieved for me, as if I were suffering something dreadful, when he sees my body either burning, or being interred; nor may say at the burial, that he lays out, or carries out, or inters *Socrates*. For," he continued, turning himself again to Crito, "be assured, excellent Crito, that the speaking improperly is not only wrong in itself, but also produces some evil in the soul. However, take courage, and say that you are burying *my body*; and bury it as may be agreeable to you, and in the manner you may hold most lawful."[3]

He then went into another apartment to bathe, Crito following him, whilst the rest of the party awaited his return. After bathing, he received his children,—two of whom were yet little ones, the third a youth,—and the females of his family. Having conversed some time with these in the presence of Crito, and given them his final commands, he dismissed them, and came out again to the assembled friends. This affecting interview had occupied a considerable time, and when he returned, it was near sunset. He had not long sat down, when the officer of the Eleven presented himself, and respectfully intimated to him that the fatal moment was at hand. The noble and gentle demeanour of the philosopher during his imprisonment had won upon this man; and used as he had been to the scenes of execration and horror within those walls, he was struck by the contrast in the case of Socrates, and bursting into tears as he gave his message, turned himself away, and retired. Socrates himself was touched by this demonstration of considerate feeling. He cordially returned the salutation, promising a ready compliance with the order. Then addressing the company, he observed, "How courteous the man is! through all the time he would come to me, and would converse with me sometimes, and was the best of men; and now how generously does he weep for me!" He then called for the poisoned cup. Crito's affection would still have delayed it, for he urged that the sun was not yet gone down, and that others on the like occasions had not used such despatch, but had supped and drunk beforehand as they pleased. Socrates answered that this might be reasonable for others; for him it was reasonable not to do so; and persisted in requiring the cup to be brought. The process of bruising the hemlock took some time; but at length the man who was to administer the poison came with it now ready for the draught. He calmly inquired what he was to do; and, being told that he was only to walk about after drinking it, until he found a heaviness in the legs, and then to lie down, he took the cup into his hand without the slightest change of colour or of countenance. But before he put it to his lips, partly, it seems, from religious feeling, and partly in humour, he further asked whether he might make a libation to any one from the cup. Nor did even his usual quaint manner of putting a question, which he knew would somewhat surprise the hearer, forsake him on this occasion; for he looked at the man, at the same time, with that peculiar glance usual to him, which his contemporaries jocosely designated by a word denoting its resemblance to the manner in which the bull glares around him with the head downward. Learning that the whole draught was not more than sufficient for the fatal purpose, he said, "At any rate one may, and ought to pray to the gods, that the migration hence to those regions may be prosperous; which indeed I do pray, and so may it be!" With these words, he drank off the poison with the most perfect composure and readiness.

At the sight of this, the bystanders could no longer command their emotions. Their tears flowed profusely. Some rose up from their seats,—Crito set the example,—and covered their faces, to give vent to their sorrow. Apollodorus sobbed aloud. He gently expostulated with them for this outbreak of grief, saying, "What are you doing, my friends, so strangely? I indeed sent away the women not least on this account, that they might not offend in such a way; for I have heard that one ought to die amidst auspicious sounds: I pray you, therefore, be tranquil, and bear up." This rebuke had the effect of repressing their tears. The heaviness which he had been led to expect from the working of the poison now began to come on, and he left off walking, and reclined, with his face upward, and covered over. The torpor gradually spread towards the upper regions of the body,—the lower parts becoming, one after the other, congealed, and insensible,—until it reached the heart. In this interval, he uncovered himself, and said, "Crito, we owe a cock to Esculapius; pay it, I pray you, and neglect it not;" intimating probably that now all the diseases of life were healed, and that he was restored to real and pure existence by the death of the body. These were his last words. Crito asked whether he had any thing more to say, but received no answer. There was no further indication of life, but a motion of the body. The executioner uncovered him, and they observed his eyes fixed; upon which Crito, faithful in the last respectful attentions to his beloved friend, the now departed philosopher, closed the mouth and the eyes.

---

[1] Plato, Phædo, p. 63, d. *et sqq.*

[2] Ibid. p. 115, a. *et sqq.*

[3] Ibid.

Thus died Socrates, when he had now completed his seventieth year, B.C. 400, or 399, in the full vigour of a healthy old age; happy in his own estimation, and in that of his admiring disciples, in having terminated his life in so glorious a manner, with unimpaired faculties of mind and body, and after a defence sustained with so much truth, and justice, and fortitude.[1]

His death spread dismay at the moment among those who had been most conspicuous in their attachment to the philosopher, as they naturally dreaded the overflowings of that malignant spirit which had swept down their master. The chief of these appear to have fled to Megara, where they could reckon on finding a refuge from Athenian hostility, and a home with their fellow-disciple, the friendly Euclid. It is remarkable, however, that Isocrates, timid as he was by nature, should not have scrupled to remain at Athens, and to testify his affectionate regret for his master, by appearing the next day in public, clothed in mourning.[2] But with the fall of its great victim, the spirit of persecution was sated for a time. An act had been perpetrated, to which the eyes of all Greece would be intently turned; and the greatness of the sacrifice seems at the moment to have absorbed the attention of its agents and instruments, in the contemplation of it and its possible effects. If we may believe the representation of subsequent writers, shame and repentance soon followed the cruel act; and those who were most ostensibly involved in its guilt, were either banished or sentenced to death, or laid violent hands on themselves. Of the banishment of Anytus, and the death of Melitus, we are told by Laertius, that Antisthenes was the immediate cause. In what way he was instrumental to the death of Melitus, is not stated. But with regard to Anytus, Antisthenes is said to have occasioned his banishment, apparently without the intention of doing so, by a stroke of practical humour. For meeting with some young men from Pontus, inquiring for Socrates, whose fame had induced them to visit Athens, he conducted them to Anytus, who, as he observed to them, was "wiser than Socrates;" upon which, the indignation of the bystanders was excited, and they drove Anytus forth from the city.[3] He fled to Heraclea; but there found no peace, being forced by public proclamation to leave the city forthwith.[4] Though, however, these individuals soon after received the retribution due to their offence, it would not follow that they suffered from their countrymen on account of the part they had taken against Socrates. The ascendancy of another political faction, (and Athens was ever fluctuating between contending parties), would be quite sufficient to account for their overthrow and desperation. On the other hand, the testimony of Plutarch is explicit to the point, though he mentions no individuals by name, that the sycophants who had assailed Socrates became the objects of popular hatred to such a degree, that none would associate with them in any way, not even to return them an answer when addressed by them, and that at last they hanged themselves, being no longer able to endure the public execration.[5] His friends, indeed, performed the last obsequies to his remains; but his fellow-citizens afterwards concurred in honouring him, by erecting a brazen statue of him, the work of Lysippus, in the Pompeium, and expressing their sorrow, by closing the public gymnasia for a while.

This at any rate is certain, that persecution, as it ever does, overwrought its part in the case of Socrates. It oppressed, indeed, the individual, but it gave the seal of martyrdom to the cause in which he had been engaged. It produced a temporary intimidation, under which men would hear less of the name and teaching of Socrates openly avowed, but throughout which the admiration and love of the heroic philosopher would be cherished in secret, and his doctrine would be fostered in the shade, to appear in the sunshine of a future day. If the Athenians had desired to plant the root of philosophy in their city, they could not more effectually have done so, than by their violence against Socrates. Such, in fact, was the result. Philosophy henceforth obtained an Athenian naturalization and name; and the schools of Athens may date their period of nearly a thousand years from this memorable act, which, in its intent and spirit, fiercely but blindly endeavoured to extinguish there the very profession of philosophy.[6]

The cause, however, in which Socrates had been engaged, was too true, for any opposition to it, though conducted with the greatest prudence, to have been long successful. It had also already advanced too far, and interested too many persons in the maintenance of it, to be put down by a sudden blow. The burning of a book, or a formal condemnation of the opinions of a writer, are but futile means, as experience shews, of suppressing obnoxious doctrines. How much less could opposition avail, where, as in the case of Socrates, the offending doctrines had been scattered over, not the pages of a book, but the strenuous exertions of a long life,—already engraved in characters which no obliterating hand could reach, and doubtless so worked into many a mind, as not to be distinguishable from its own proper convictions,—doctrines too, so confirmed by the noble example of their teacher, in carrying them out to their full consequences by his death? For the death of Socrates, it should be observed, was not simply a test of his sincerity in his teaching. It was this, and still more. It was the ultimate and decisive opposition to those false principles, against which every action and discourse of his life had been directed. He had been all along exposing the presumptuousness and vanity of the principles on which men ordinarily judged and acted. He was now further to shew, that this opposition on his part was not to be daunted by those principles, when set in formidable array against his own life; and that, professing a low estimate of the present life, he would not disown or shrink from that profession at the moment of greatest trial.

If we inquire, accordingly, what was the substance of the positive teaching of Socrates, we must address ourselves to the contemplation of his active life, and his resigned patient death. He had no design of establishing philosophy as a literary pursuit or intellectual pastime; though he probably foresaw, that that taste for inquiry into truth which he was ever awakening, must soon lead to the formation of a philosophical literature at Athens. He already witnessed, indeed, the commencement of such a literature, the result of this excitement, if it be true that he had read the Lysis of Plato, and observed respecting it, "How much the young man makes me say that I never said!"[7] He wished rather to divert men from the vanity of setting themselves up as philosophers, and make them employ their thoughts in learning and investigating, instead of prematurely commencing at once as well-informed persons and teachers of others, with crude and superficial notions and principles.

[7] Diog. Laert. in vit. Plat. xxiv.

If we look, then, to the course of his practical teaching,—to the general tenor of his conversations and actions, and the example throughout of his life and death,—we shall find that his whole labour was directed to the establishment of true moral and religious principles, in opposition to the false and mischievous principles which, he observed, were commonly acted upon and avowed in the world. The excellence and supremacy of self-knowledge was what he was ever inculcating; and of self-knowledge, not as a matter of intellectual curiosity, or for its value as a science, but in order to self-government and to happiness. He found that this was the last kind of knowledge which men ever thought of acquiring; that they had, in fact, no concern about it; or that if they were reminded of its necessity, they presumed on their possession of it already. His first effort, then, was to open the minds of men to a perception of the value of this knowledge, and of their own need of it. The questions which he would put—the refutations which he addressed to the various propositions or conclusions elicited from others in the course of his conversations—the perplexities to which he would reduce them—and the unsatisfied state in which he would commonly leave them, after exciting their doubts—all had a direct tendency to convince men of the insufficiency of their intellectual acquirements, and of their want of some more adequate and availing information.[1] To the same purport was his disparagement of physical science, and of all merely speculative knowledge, in comparison with that which was useful for human life. For he was far from an utilitarian, in the modern sense of that term. He did not value particular studies, because they ministered to the necessities or conveniences of human life, or undervalue them because they had no such bearing. But he saw that his clever and ingenious countrymen were studious of intellectual refinement—that they delighted in the specious, and the admirable, and the subtile, more than in the solid and the unostentatious qualifications of the good member of a private family and the useful citizen. He was aware, too, from his own acquaintance with the existing physical philosophy, how imperfect that knowledge was, how entirely hypothetical, and incapable of practical application. We must make allowance, therefore, in estimating his objection to speculative science, for the polemical spirit in which he assailed a branch of knowledge then, at once, so barren, and so encroaching in its claims on public attention. We must regard him as preparing the way for the due cultivation of the other, the higher as well as more important knowledge, that of man's own nature, then so little thought of, and so neglected. This seems to be invariably his design on every occasion, whatever may be the immediate purport of his discourse.

When he came to direct the minds of men, once awakened to the importance of moral study, to the subject itself of human nature, he had to encounter on the very threshold the most perverse notions. All their maxims of life were based on the absolute importance of the present life. The body, and its present appetites and desires, were regarded as the whole of man. The tyrant, in the enjoyment of absolute power to gratify every passion without restriction or penalty, was considered as the apt representation of the highest human felicity. All men's plans of life accordingly were directed to the acquisition of power for themselves. They studied to improve their external circumstances, and not themselves. Then their religion was merely the fear of mysterious powers influencing the prosperous or adverse events of the present world, and which were therefore to be conciliated or appeased by offerings and vows. Socrates set himself strenuously to refute these vain presumptions. He argued the folly of supposing, that men really accomplished their own wishes in gratifying each prevailing inclination. He showed, that whilst they did what they pleased at the moment, they did not in fact attain that pleasure which they sought; and led them therefore to surmise, that there must be some end of human pursuit beyond the gratification of the passions, and further, some ultimate end to the whole sum of the active energies of the soul, beyond the present life, and distinct from all bodily associations. But he not only suggested such a thought by shewing the reasonings on the opposite view of human life to be inconsequential and absurd; he further practically refuted the prevailing fallacies on the subject, by his own example on the other side. He proved to the world, by divesting himself of all the worldly accessaries of happiness, and depending exclusively on the internal resources of his mind and character, and by his perpetual cheerfulness under those privations, that happiness did not result from externals, or from the body, but from the internal nature of man, nor from any thing positive and absolute in that nature, so much as from its state of discipline and command over the appetites of the body. Theories of morals were yet to be formed. It remained for Plato to erect the true and sublime standard of human conduct in the perfections of the Divinity, and for Aristotle afterwards to shew the application of the law of habits to the subject. Socrates has the merit of having prepared the way for these developments of the subject, by demonstrating the folly of seeking the ideal of happiness in any enjoyment of the body, or in any thing present.

So also as to religion, though he could not advance, in his conceptions of the retributive justice of the Divine Being, beyond the circle of darkness which limits the natural observation of man, he proved the absurdity of supposing that mere external punishment was the only suffering undergone for offences committed. Secret faults, as he pointed out, did not escape with impunity. He appealed to the remorses of conscience, to shew how surely, however invisibly, wrong doing was visited with its punishment; and whilst in his own mind he concluded that there would be a future state, in which each man would receive the merited consequences of his actions, he must also have excited, in the minds of his hearers, a strong though undefined apprehension of a period of general retribution after death in another world. At least they must have seen that it was not so certain, as they may have once supposed, that though a present punishment may have been evaded, punishment would not follow at a future day. In well-disposed minds, there would thus be a foundation laid of a doctrine of the immortality of the soul. Under the teaching of Socrates himself, this truth, perhaps, would scarcely assume the form of a doctrine, so distinctly as it is stated by Plato. It would be simply a practical conviction. And thus Socrates himself probably scarcely propounded it in formal terms, nor without those qualifying doubts which both his memorialists describe him as joining with its enunciation. But Plato, following him, took up the doctrine as a formal truth, and worked it up into a perfect theory, with the formal array of argument and didactic exposition.

There was nothing, indeed, of system in any part of the teaching of Socrates. In the "Memorabilia" of Xenophon, we have probably a very complete specimen of the substance of what he taught, and, in the desultory manner in which the subjects of the several conversations there given are introduced, of the actual way in which he would throw out his questions and reflections on different points, as they happened to suggest themselves on each occasion. There we find the various duties of the good man and the good citizen summarily sketched, without the formality of statement or systematic connexion. He inquires what is just, or pious, or temperate,—and he leads his hearers to consider the true definitions of the several virtues;[1] but it is chiefly with the view of laying open their mistakes and confusion of thought on the subject, and to divert them from sophistical disquisitions on virtue, to the discharge of virtue in all its parts, rather than to give any precise idea of it himself.[2]

---

[1] Xenoph. Mem. iv. 3. 36. Ἀλλὰ ταῦτα μὲν, ἔφη ὁ Σωκρὰτης, ἴσως διὰ τὸ σφόδρα πιστεύειν εἰδέναι οὐδ᾽ ἔσκεψαι. . . . Ib. 39. φροντίζω, μὴ κράτιστον ᾖ μοι σιγᾷν· κινδυνεύω γὰρ ἁπλῶς ὀυδεν ἐιδέναι.

Certainly there are grave objections to the morality which he taught. It did not enjoin that perfect purity of sentiment and action, which, judging from its general excellence, we might perhaps have expected. It forbade *excesses* of licentiousness as evil, but it did not also forbid licentious indulgence as altogether vicious, or fix its stigma on those monstrous forms of vice which polluted Grecian society. Nor, again, did it give a right tone to the resentful feelings. It enjoined the requiting of ill to enemies,—placing retaliation as a duty on a par with the return of kindness to friends.[3] With these exceptions, the morality inculcated by Socrates, founded as it was on the indications in man's nature of a destiny beyond the present world, bears strongly the marks of the law written by the finger of God, and proves that the Creator has not left Himself without witness, where the light of his revelation has not shone. Supposing even that those great truths, thus taught, were the broken planks from the wreck of a primitive Faith, floated down on the stream of ages, we must yet believe a providential disposition, in the fact of that ready acceptance which they could obtain with one, brought up, as Socrates was, amidst the grossest corruptions of heathenism. His was an instance, how the unsophisticated heart responds to the notices of divine truth, when once they are duly presented to it; and how, wherever there is a sincere pursuit of right, the moral eye will be enabled to pierce the surrounding gloom, and to discern, for the most part, the true outline and form of right.

It is observable, however, that, whilst Socrates correctly perceived that the laws of religion and morality possessed a sacred importance, independently of all positive enactments of men, he yet appeals to the laws of the state for the particular rules of religious and moral duty. When instructing Euthydemus on the worship of the gods, he cites the Delphic oracle, which enjoined the law of the state as the rule of acceptable worship.[4] When asked by the sophist Hippias what is just, he answers, that it is what the laws prescribe. Such reference was perfectly natural in a Greek, accustomed as Greeks were to view every thing in subordination to politics, and to regard the duty of the citizen as paramount to every other duty. This feeling had its influence with Socrates, and induced him to regard the authority of the state as possessing in itself a moral force of obligation. The respect which he throughout shewed to the laws of his own state, was that of one who not only obeyed what they commanded, but strictly reverenced their authority.[5] We must not, however, suppose, that he thus intended to place positive and moral laws on the same footing. The reference which he gives to the written law of the state, as the directory on questions of religion and morals, is the substitute in his teaching for a systematic development of the moral and religious duties. The law of the state presented, to one who had no thought of systematizing the subject for himself, the best expression of those great truths which he was drawing forth from the higher source of man's eternal nature. He is content to point out to his hearers, in a general way, the wisest and readiest collection of rules for those cases which came under the great comprehensive duties of piety and justice. Evidently he is not treating the subject with the exactness of the theorist, in assigning this importance to the law of the state; but he is enforcing the use of the law of the state as an authoritative practical guide to right conduct.—His internal view of religion, for example, was founded on observation of the signs of benevolent design throughout the material and intellectual world; and he was thus led to the acknowledgment of a pure Theism. But in his conduct, he knew not how to realize the obligations which the perception of this truth imposed on him. With his reverence, accordingly, for the laws of his country, as well as under the influence of that superstition to which his piety habitually verged, he sought a direction to his religious sentiments from the authority of the state, and thus in practice was a polytheist.—His object was further to prevent men from trusting to the conceits of their own judgment in matters of conduct, and to recommend a proper deference to the wisdom and authority of their ancient laws, then so presumptuously slighted by each vain pretender to superior prudence and political sagacity.

In assailing, as Socrates did, the follies of his countrymen by the dexterity of an acute reason, he was ever exposing their ignorance. The impression on his own mind appears to have been, that men erred rather from the want of due information respecting their moral condition, than from the perverseness of their will,—from folly, rather than from vice. Himself an accurate observer of human life, and with a disposition to follow the path of duty wherever it might lead him, he had in his own case felt the importance of intellectual cultivation, in order to right conduct. From his own circumstances, accordingly, and a natural predilection for those exercises of the mind which were his habitual pursuit, he overrated this importance; and, instead of simply regarding the information of the mind as a necessary ingredient in moral improvement, he made it all in all. Thus, according to him, wisdom or philosophy was virtue, and ignorance and folly, vice. He carried this view of morals so far, as to place the knowledge of duty on a footing with the knowledge of arts. Nor was he even startled with the paradox, that if such were the case—if the knowledge of right were the whole of morality—there would be less immorality in intentional wrong conduct, than in unintentional done through ignorance.[6]

[2] Xenoph. Mem. iv. 4, 9. Ἀλλὰ μὰ Δι', ἔφη, οὐκ ἀκούσῃ, πρίν γ' ἂν αὐτὸς ἀποφήνῃ, ὅ τι νομίζεις τὸ δίκαιον εἶναι. ἀρκεῖ γὰρ, ὅτι τῶν ἄλλων καταγελᾷς, ἐρωτῶν μεν καὶ ἐλέγχων πάντας, αὐτὸς δὲ οὐδενὶ θέλων ὑπέχειν λόγον οὐδὲ γνώμην ἀποφαίνεσθαι περὶ οὐδενὸς, κ.τ.λ.

[3] Xenoph. Mem. iv. 2, 16; ii. 6. 35. Aristot. Rhet. ii. 23.

[4] Ibid. iv. 3, 16. Also, i. 3, 1.

[5] See, in the "Crito" of Plato, a beautiful address, put into the mouth of Socrates, from the personified majesty of the laws.

[6] Xenoph. Mem. iv. 2, 20. Δοκεῖ δέ σοι μάθησις καὶ ἐπιστήμη τοῦ δικαίου εἶναι, ὥσπερ τῶν γραμμάτων, κ.τ.λ. Seneca, arguing also the need of moral information for the performance of duty, refers to the same illustration of morality from the arts, as that given by Xenophon, to shew that there is no real analogy between the two subjects. "Vis scire," he says, "quam dissimilis sit harum artium conditio et hujus? In illis excusatius est, voluntate peccare, quam casu: in hac maxima culpa est, sponte delinquere. Quod dico, tale est. Grammaticus non erubescit solecismum, si sciens facit: erubescit, si nesciens. Medicus, si deficere ægrum non intelligit, quantum ad artem, magis peccat, quam si se intelligere dissimulat. At in hac arte vivendi, turpior volentium culpa est." Ep. 95. 8. He seems to have had the argument of Socrates, as given by Xenophon, (Mem. iv. 2, 20.) in his view. So also Aristotle says: Καὶ ἐν μὲν τέχνῃ ὁ ἑκὼν ἁμαρτάνων αἱρετώτερος· περὶ δε φρόνησιν ἧττον, ὥσπερ καὶ περὶ τὰς ἀρετάς. Eth. Nic. vi. 5.

Thus vice was in no case, in the view of Socrates, an act of the will, but of the mistaken judgment. He did not mean by this to assert, that men did not act wrong wilfully in the particular instances of misconduct, so as not to deserve blame for their misconduct; but that the seat of vice was in the perverse understanding,—for that the will was invariably towards good. If, accordingly, vice may be regarded as seated in the understanding, and not in the heart, it would follow, that that man is less vicious in *principle*, who knows what is right and acts wrong, than one who acts wrong without knowing what is right. The former alternative, however, was impossible, according to his theory. For knowledge, by its intrinsic excellence, must prevail over every other principle. So far was Socrates led by the working of his method, and his observation of the ignorance and folly of men, to overlook facts, at least, as evident on the other side,—the plain instances of men acting wrong in spite of their better knowledge, and of greater blame assigned to wrong thus done in spite of knowledge. His error is further to be traced to a confusion of the ideas of right and happiness, in the term "good." That the will is, by the original constitution of man, invariably towards good, if we take good in the sense of real interest or happiness, is quite true; but it is far from true, if we include the notion of right in that of good. Men, when they take even perverted views of their happiness, may be regarded as unconsciously desiring the real happiness of their nature. The will, therefore, in this sense, may be said to be always towards good. But in the latter sense of the term "good,"—that in which it includes right,—the contrary rather is true. Men see the light, but love darkness rather than light; and the seat of vice is, accordingly, not in the understanding, but in the heart. But there is this justification of the language of Socrates on moral subjects, that the ignorance which he attacked, was, in truth, a vicious and blameable ignorance. Men did not take pains to inform themselves on moral subjects. They neglected themselves, pursuing and professing every other kind of knowledge but that which was most at hand for their acquisition, and most concerned them. Seeing, then, the moral errors into which men ran from this neglect, Socrates not unreasonably set his mark of reprobation no ignorance, as the source of immorality. Immediately, indeed, and ostensibly, he attacked the general ignorance of men, holding out philosophy as the remedy of vice and unhappiness. But the ultimate and real object of his attack all the while was, the immoral disposition, the self-neglect, and the irregular habits of life, from which the incapacity and ignorance of men on moral subjects commonly result. Then, further, it was the ignorance of self, chiefly, that he laboured to remove. He found conceit as to themselves, the prevailing fault of the men of his age and country. And he hoped, by exposing their ignorance on various subjects, to make them question their presumptions relating to their own nature, and character, and duties. Thus would he, in effect, be correcting moral error,—the folly of men persuading themselves and others that they knew what they had never cared to examine, much less to know.[1]

As the peculiar aspect under which he presented the subject of morals arose, in a great measure, from his manner of interrogating in conversation, so the general character of his philosophy is to be sought in its intimate connexion with the peculiar method which he pursued. His philosophy, being essentially colloquial, laid down no positive principles in any particular science, or even any general principles for the conduct of the understanding in scientific or moral inquiries. But it sought to rouse the understanding to a perception of its condition of weakness, and defects, and ignorance, previous to its interrogation of itself, and its acquisition of knowledge, and its strengthening by exercise and discipline. Like the great reformer of modern science, he found nothing duly ascertained in the field of philosophy; hypotheses assumed without examination, truth obscured and confounded under the plausible cover of general terms and vague analogies. Yet every one was fully satisfied with the state of knowledge; every one presumed that he was in possession of the truth. So, too, at this period, as at the time when Bacon proposed his new method, there was a dialectical science in use, available only for disputation and victory, and not reaching the truth of things, or imparting any real knowledge. And, in like manner, in the time of Socrates, as in that of Bacon, this imperfect dialectical science was regarded as the key to every kind of knowledge; and he who could discourse fluently on any given subject, was esteemed the accomplished philosopher. "Of nothing," as Bacon himself pointedly observes, "were men so scrupulous as lest they should seem to doubt on any subject."[2]

This state of things formed a strong barrier against any attempt to effect a moral reformation. The way to the heart had to be cleared through a mass of outworks thrown out by the intellect. It only remained, then, for him who would be the moral reformer of his countrymen, to work by means of that very dialectical science which opposed its ramparts and its arms to his progress.

But to have simply used the same method which his contemporaries employed, would have been to revolve in the same perpetual circle. Socrates, indeed, might, by a more skilful use of the same dialectical artifices, have confuted the sophists and others with whom he reasoned. He might have gained the victory in argument, by demonstrating the fallacy of their deductions, or proving the contradictory of their conclusions. But no advance would have been made by such a proceeding towards a detection of the source of the popular errors, the wrong principles themselves, on which men argued and acted. To accomplish this object, then,—to expose the fallacy of wrong principles,—he had to exalt the art of the dialectician to a higher function than that of merely eliciting consequences from given principles.

This attempt accordingly he made. Without instituting any formal method, or teaching any art of discourse,—without, it seems, having any such design in his thoughts,—he yet so far gave a new direction and impulse to dialectical science, as to render it in some measure at least subservient to the investigation of truth. In his hands, it served, if it did nothing more, to raise *doubts* as to the truth of erroneous principles which before had passed without question, and which the very practice of reasoning from them as axioms, had tended to confirm as fixed and indisputable standards of all other truths.

We must not suppose, that definition and induction were unknown as parts of dialectics before Socrates; or that Socrates was absolutely the first to discover and propound their nature and use. The expressions of Aristotle might suggest this supposition. For he says particularly, that there were two things which one might ascribe to Socrates, Definition, and Inductive Reasoning.[3] What Aristotle probably intends to say, is, that Socrates was the first to improve the existing method of dialectics, by employing definition and induction as the principal engines of discussion, and illustrating their nature and use more than ever had been done before him. He gave them, in fact, a body and a vitality, by applying them to the realities with which men had to do in their daily life.[1] Instead of employing them for the purpose of verbal distinction, or for the expression of some abstract and barren generality, he applied them to limit the vague notions entertained about matters of practical concern, and to bring opinions into harmony with ordinary experience. To the dialecticians before him, Definition and Induction were the commencement of their discussions. They unsuspectingly presumed on the logical processes involved in these instruments of discourse, as already sufficiently accomplished. They attempted, indeed, to define; but they took such definitions as they found at hand,—of course the most superficial.[2] General principles they scarcely though of establishing; but they assumed such as were the current maxims of the day. And the rest of their discourse proceeded from these crude and unscientific elements. But Socrates did not profess to give definitions, or to have arrived at any positive certain principles, from which, as data, other truths might be demonstrated.

---

[1] Xenophon speaks of the refutations employed by Socrates, serving as chastisements of presumptuous folly, κολαστηρίου ἕνεκα. Mem. i. 4. 1.

[2] Nov. Org. i. 67.

[3] Aristot. Metaph. xiii. 4. Δύο γὰρ ἐστιν ἅ τις ἂν ἀποδῴη Σωκράτει δικαίως, τούς τ' ἐπακτικοὺς λόγους, καὶ τὸ ὁρίζεσθαι καθόλου. Ibid. i. 6. περὶ ὁρισμῶν ἐπιστήσαντος πρώτου τὴν διάνοιαν.

He disclaimed, as has been already pointed out, the design or the ability to teach. He was only an inquirer, himself *knowing nothing.* When pressed, as by the sophist Hippias, to give his own account of the particular subject about which he is importunately questioning, he evades the point, and recurs to his established way of proceeding by interrogatories.[3] He is constantly, that is, endeavouring to rise to a correct definition of the subject under discussion. He presents it as the end to be attained by the whole discussion; leading the person questioned from point to point, until he brings him close to the true and exact idea of the subject. So also does he employ Induction. He cites some instance,—commonly some coarse and very familiar one, from the workshop of the smith or the shoemaker, or from the culinary art, and the like,—as apposite to the point under debate; and thus brings the principle itself, on which the dispute turns, to the test of actual experience. This was so much his manner, that it was made a standing jest by those against whom he so triumphantly employed it. They complained of his ever repeating the same thing; ever talking of "carpenters, and smiths, and fullers, and cooks, and such like nonsense.[4]" But he was not deterred by the scoff, which in reality proved the point and force of his reasonings. He replied, that about the same things, he must persist in saying the same things; unless it could be shewn, that a person being asked, whether twice five were ten, should answer differently at different times.[5] Thus, he would continually recur to his well-known illustrations from common life, hackneyed as they were in his own use, and low and trifling as they might seem.

From this his constant practice of bringing men to the test of definition and familiar instance, on every subject discussed, he had been regarded by the Thirty as the teacher of an "art of discourse," and as therefore obnoxious to a law which they had made (chiefly with a view to him), forbidding the teaching of such an art.[6] Such a restriction, however, could not apply to Socrates; since, as we have seen, he professed no art; he imparted no method of argument; and, to have silenced him, they must, as he shewed them, have absolutely prevented his asking the most simple and familiar question. Here it was the point of an apt illustration that had provoked this sally of resentment from Critias and Charicles, two of the Thirty. It had been reported to them that he had drawn attention to their acts of violence, by asking, what would be thought of the herdsman under whose care an herd should be diminished. On this occasion, Charicles, after vainly remonstrating with him against the practice of his daily conversations, shewed the point of the illustration, by bidding him beware lest he also should make the number of the herd still less.[7]

So far, indeed, was Socrates from instituting any method either of argument or of investigation, that the very definitions and instances which he employed were of a popular character, adapted for refutation of error rather than for conviction of the truth,—such as to place difficulties in the way of a dogmatic opponent, rather than didactic illustrations of any particular subject. He was engaged in repelling dogmatism. And nothing is of more avail for this purpose than analogies; such instances, that is, as test the truth of an assumption in one case, by its application to another of the same kind. Direct instances, shewing experimentally the truth or falsehood of an assumption, may be difficult to be found; and, in their use, they require a particular acquaintance with the subject itself, in order that their application may be seen. For example, if it were desired to expose a false theory of government, some fact of history must be adduced, and its bearing on the theory in question must be distinctly pointed out. But an analogous instance does not require this intimate acquaintance with the subject itself, in illustration of which it is brought. It shews at once that a given hypothesis is either tenable, or not tenable,—that it is verified or not verified in some parallel case, and therefore may be granted or not, in the subject about which the argument is. Only it is necessary, for this purpose, that the analogous instance should be a familiar one,—that the exhibition of the principle in question should be clear and striking in the instances adduced. For example, to set forth the evil of tyranny, it would be quite enough to point out, as Socrates did, the case of a herdsman under whose keeping an herd should be deteriorated; and the inference would be immediate, that a career of confiscation and blood was no evidence of a good government. Again, whether it were wise to choose magistrates by lot, would be a difficult question to be decided by the direct evidence of facts bearing on the point. But when Socrates referred to the absurdity of appointing a steersman by lot, it was at once evident, that there were cases in which this mode of appointing important officers of the state would be mischievous. Such then was the kind of evidence which Socrates was constantly adducing from analogous instances to the point in question;—an evidence, not conveying any positive instruction in the theories of the subjects to which it was applied; but removing false impressions respecting them, and opening the mind to the reception of the truth. It was an admirable method of unteaching prejudices or vain assumptions, and of silencing the dogmatist,—a method, powerful at once for the refutation of error, and the conviction of ordinary minds incapable of being instructed by a more direct and positive evidence. Such, accordingly, was the method practised by Socrates. In pursuing any argument, "he would proceed," as Xenophon observes, "by the most admitted principles; considering this to be the sound basis of discussion. And therefore," adds Xenophon, "he, far beyond all I ever knew, when he spoke, carried conviction to his hearers;" and he would say, "that Homer had ascribed to Ulysses the merit of being a sound orator, on account of his ability to conduct a discussion, by reasoning from such principles as men acknowledged."[8]

It was seldom, however, if ever, that Socrates avowedly argued a point. Professing to know nothing himself, he constantly challenged others as to what they professed to know. He put his questions to each person with whom he conversed, very much as the skilful experimenter in these days does to nature, so as to lead to the affirmative or negative of a particular hypothesis whose truth he would investigate. Having obtained an answer, he proceeds analytically, to found on that another question, studiously directed, in like manner, to elicit the answer which might serve for further inquiry, and so on, until he has reduced the first proposition to some simple elements, clearly shewing the truth or falsehood of the original assumption. It was as truly an experimental process on men's minds, as that which the modern investigator performs on the subject which he examines. Those analogical instances in which he so much delighted, served the purpose of this analysis, no less than direct and proper instances, such as belong to him who investigates experimentally the nature of a particular subject. For analogies detect the state of the mind to which they are addressed. They at once call forth and illustrate its principles and habits of thought, and enable the experimenter to avail himself of the existing resources in that mind for effecting the desired conviction. They furnish him with a clue to the course which he should follow in carrying on his analysis. This was that midwifery of the mind which Socrates used sportively to describe as his peculiar occupation.

In his conversation, for example, with Euthydemus, who prided himself in having cultivated his mind by his own independent study of books, of which he had formed a large collection,—he first drew attention to the singularity of the young man's conceit, by representing him as coming before the public, with high professions of being self-taught, and putting the parallel case of a candidate for some medical office, who should announce that he had studiously avoided even the appearance of having *learned* the art of medicine, and ask for the office on the promise of endeavouring to learn the art by his future practice. Interest being excited by this illustration of the absurdity, he next led his hearers to see the absurdity of entering on political affairs without preparation, by referring to the fact of the severe application and discipline undergone by persons who seek reputation in such accomplishments as flute-playing or riding. Then, having gained over Euthydemus as a more willing listener, he proceeds to question him as to the use for which he had collected so many books. He throws out the presumption that they have been collected with a view to enrich the mind with virtue. Supposing this to be granted, he goes on to interrogate Euthydemus as to the particular excellence of which he is in quest. He enumerates several particulars; and these being rejected, he comes at last to excellence in the art of government, which the young man concedes to be the object of his desire. This gives an opening to inquire into the qualifications necessary for such excellence. He discovers, by the answers of Euthydemus, that he conceives himself master of those moral virtues which he is induced to admit are indispensable to the good citizen. By a series of questions, however, relating to particular actions, he forces Euthydemus to admit, that what is just in one case, is unjust in another, and to contradict himself in his successive statements as to the comparative criminality of voluntary and involuntary acts of injustice. What, then, triumphantly asks the philosopher, think you of a person who is so inconsistent with himself? The conclusion is inevitable; and Euthydemus is constrained to own, that " he knew not what he thought he knew." But Socrates, not yet satisfied, presses him further to explain his notion of that ignorance which he had thus displayed; and finds, that notwithstanding his confession of his want of right instruction, he yet presumes on his possession of self-knowledge. Another question forces him to abandon this position. The young man then asks to be only put in the way of self-examination. Here at once his false presumptions are exposed to the searching analysis of Socrates. The inquiry turns on a knowledge of the goods and evil of life. Euthydemus enumerates one thing after another as good; and Socrates immediately subjoins some counter evil as attending it; until Euthydemus at last gives up his confidence in his own opinion, and declares that he knows not now what he ought to pray for to the gods. Again, Socrates presents before him pointedly the evidence he had thus given of having been diverted from consideration of the subject by the strong presumption of his knowledge of it. But that he may leave no room for escape, he calls on him, in conclusion, to state his opinion as to the nature of democracy, which at least, he conceived, Enthydemus, as a candidate for public office in a popular state, must have studied. And in like manner, he extorts from his successive answers a further proof of his ignorance and incompetence to the duties for which he had designed himself.

The effect thus produced is what Plato compares to the numbing touch of the torpedo.[1] The mental powers of the individual thus tried were for the moment paralyzed. He found that he only committed himself further by renewed efforts; and " began to think," as Euthydemus says of himself at the close of the conversation to which we have just referred, " whether it were not best for him to be silent, as he ran the hazard of appearing absolutely to know nothing."

From the instance just given, it will appear that a current of irony pervaded these experimental argumentations of Socrates. There was irony mingled with earnest conviction, in that very disclaimer of all knowledge with which he set out. It was a mask, behind which he could hurl his weapons of assault on the boasted knowledge of others, whilst at the same time he expressed his serious view of the real ignorance of man, and the necessity of coming with a simple unprejudiced mind to the acquisition of truth. In the prosecution, however, of his method of analysis by interrogation, irony was indispensable for the success of his inquiry. For his object was to obtain the truth from the mouth of the person interrogated, not to state it himself; and where he did state it accordingly, it was necessary to put it in such a form as to try whether it was the opinion or not of that person,—whether he really thought so, or adopted it on the judgment of his questioner. An ironical statement answers this purpose. It conceals the teacher, and enables him to judge, according as the hearer applies it, what the state of the hearer's mind is, and to argue the point in question, not on premises laid down by himself, but the admissions of the other. The hearer, too, is taken by surprise. The air of seriousness which the ironical manner sets out with, and the absurdity involved, on second thought, in carrying out the supposition of a serious intent, in their united effect, provoke the smile of surprise, and win attention. As Socrates was engaged, too, in presenting unacceptable conclusions,—bringing home to the self-conceited evidences of their real ignorance,—it was necessary for him to disguise, as much as possible, the conclusion to which he was tending. He had to assume, therefore, the principles on which those with whom he conversed were reasoning and acting, and reduce these to an absurdity, by applying them as true to some evident case of ordinary experience. The skilful use made by Socrates of this irony was a powerful enforcement, in itself, of the convictions which he desired to leave on the minds of his hearers. He brought the aid of a delicate ridicule to the support of an argument, and thus exhibited the desired conclusion under a form, which, whilst it pleased the hearers, shamed them into an acknowledgment of its truth.

---

[1] Plato, Meno., 80 a. t. iv. p. 348.

But this irony, and the analogical instances over which it was thrown, were but approaches to that end which Socrates appears always to have had in view in his conversations,—the ascent to accurate general notions of each object of thought. He was always working his way towards an exact definition of the idea on which the discussion turned. Each instance which he adduced was a step in this progress, diminishing by its light some portion of that obscurity and confusion of thought with which he found the subject invested. He did not, indeed, reach the point which he had in view. Dialectical science was in too rude a state at present for the attainment of its perfect end. Socrates rather set an admirable example of the perseverance and energy with which the end should be pursued, than a perfect model of the method of pursuing it. His very method, indeed, confesses its own imperfection, in stopping just at the point where the way seems to be opened, and leaving the subject negatively, rather than positively defined.

This constant pursuit of exact definition is an indication of the antisceptical bent of the mind of Socrates. The foundations of morals and of all science were shaken by the speculations of his sophistical predecessors. Opinion was exalted to the prerogative of knowledge. Socrates accordingly put opinion to the test. He explored it experimentally, as it existed in different minds; and he proved it deficient from the standard to which it had been vainly exalted. He found that it vanished before the light of investigation; and, in fact, that in proportion as the fancies and errors of opinion were cleared away, advances were made towards more stable and certain knowledge. This knowledge, accordingly, he continually sought after. He had probably but an indistinct conception of the realities towards which he directed his pursuit. Still he appears constantly to have assumed and fully believed their existence, by steadily proceeding, as we find him to have done, through the various opinions which he encounters in discussion, until he arrives at some more definite form of thought. What Socrates only indistinctly apprehended, Plato afterwards realized in his philosophical system, and endued with existence in his celebrated theory of Ideas. But in the view of his master that theory was but dimly seen in shadow. Socrates shaped his course towards it, as he more and more limited the extravagancies of popular opinion on the various subjects which he discussed, and excluded whatever was irrelevant and foreign to the real nature of the thing. He threw doubts on what was doubtful, that there might be the less doubt and uncertainty about what remained when the doubtful was removed from a subject.

What appears to have led Socrates into this sound method of proceeding, was, as Aristotle very justly intimates, the firm moral convictions which were the great elements of his mind and character.[1] He felt that there was a reality in the principles of piety, justice, benevolence, and other moral sentiments, which no sophistry could impugn. He not only felt their reality within himself, but he had observed, that however invisible to the outward eye, they produced real effects in the world; that they were not only evidenced in the constitution of nature, but also recognized in those unwritten laws which were found everywhere the same, independently of positive institution, as well as in the enactments of particular states.[2] He looked for the original of these sentiments to the perfect nature of the Divinity; and he held them accordingly to be invariable and true, as the Divinity is invariable and true. Hence he would allow no proper and adequate power of causation but moral design. Material or mechanical causes were in his view but of instrumental efficacy.[3] It was moral sentiment only, the love and pursuit of good, that possessed real power. This alone, he observed, subsisted unchanged and fixed, whilst every thing else was moved by it, and derived its existence from it. It was the neglect of this primary principle in the detail of the physical theory of Anaxagoras, which had offended him in the system of that philosopher. And agreeably to this, Plato tells us of his accounting for his remaining in his prison, from the simple cause of the moral feeling by which he was actuated.

Fixing his eye accordingly on these stable eternal principles, Socrates pressed forward in every discussion towards their attainment. He would never rest in vague general classifications, which involving also much that belonged not to the subject in question, left its nature as undefined as ever. But he proceeded to a further limitation of the generalities on each subject, obliging his hearer to distinguish the subordinate genera included in the more general idea first thrown out, and thus gradually to circumscribe the subject within its proper boundaries. This was the intimate connexion of his logic and ethics. He was engaged throughout in an endeavour to remove the vain presumptions of mere opinion, and to substitute for these a real knowledge, as far as it was attainable, of the subjects themselves. He conceived that if men went astray in their conduct, acting on what they mistakenly thought right, and good, and true, it was only necessary to make them *know* the truth, and they would then act on their *knowledge*, as before they acted on mere *opinion*, and by thus acting attain their happiness. This was but a short-sighted view of the origin of human misconduct and unhappiness, as it did not go beyond the fact of the erroneous judgment of men, to the moral perversion which was the primary cause of their failure in action. As the practical error of men arises from this perversion, it is evidently vain to think to improve their conduct, by merely substituting more correct notions of truth and duty; since this remedy does not reach the source of the malady. Such, however, was the view of Socrates. And hence he laboured, whatever might be the subject of his conversations, to lead men to contemplate the nature of the thing discussed, and to seek to define it to themselves; thus blending the perception of the right and the good in the intellectual apprehension of the truth. Xenophon accordingly remarks the importance attributed by Socrates to the ability of distributing things into genera, on the ground, that by means of this talent "men would become most virtuous, most formed for command, and most able in discourse."[4]

Though Socrates thus endeavoured to render his hearers accomplished in the art of discussion, by directing their attention to Definition, he, as might be expected, in that early state of logical science, did little more than point out the great importance of Definition, and mark the direction in which it should proceed. Were we to take our estimate of what Socrates accomplished in this way from the "Dialogues" of Plato, we must suppose Socrates to have been much more methodical in his discussions, than we should infer from the specimens given by Xenophon. Something perhaps should be allowed for the practical turn of Xenophon's mind, and his comparative inattention to the more abstract part of the discussions of his master, whilst his fellow-pupil, on the other hand, who had an eagle-eye for theory, however remote and dazzling, would seize every hint that dropped from the lips of Socrates for the indulgence of his speculative imagination. Still Xenophon may be regarded as having presented the most natural, as well as most exact, specimens of the method of Socrates. In the simplicity of his honest admiration and grateful recollection of the instructor and guide of his youth, he evidently records what had most impressed his own mind, both as to the substance and the manner of the conversations of Socrates, without any attempt either at dramatic or theoretic effect. From Xenophon we learn how Socrates appeared to the young Athenian, who, without any theories of his own, approached him, simply with the desire of hearing him, and applying what he might learn from the philosopher to his own improvement. Plato, on the other hand, whilst he also has given a faithful portrait of Socrates in the general outline, (and the faithfulness is shown by its close correspondence with that given by Xenophon,) studied to give effect, at the same time, to his own philosophic sketches, by placing the figure of Socrates in such a light as to harmonize with his own sublime and beautiful ideal of truth.

[1] Aristot. Metaph. i. 6. *Σωκράτους δὲ περὶ μὲν τὰ ἠθικὰ πραγματευομένου, κ.τ.λ.*

[2] Xenoph. Mem. iv. 4.

[3] Aristotle gives an instance of the manner in which Anaxagoras lost sight of his theory of mind in working out his system. Anaxagoras, he tells us, said "that man was the most intelligent of animals, because he had hands; whereas he should have stated, that man had hands because he was the most intelligent of animals; for that hands were an instrument for taking hold." Aristot. de Part. Anim. iv. 10, p. 1034. *'Αναξαγόρας μὲν οὖν φησὶ, διὰ τὸ χεῖρας ἔχειν, φρονιμώτατον εἶναι τῶν ζώων τὸν ἄνθρωπον· εὔλογον δὲ, διὰ το φρονιμώτατον εἶναι τῶν ζώων, χεῖρας ἔχειν· τοῦ λαμβάνειν γὰρ χεῖρες ὀργανόν εἰσιν.* Ed. Duval.

[4] Xenoph. Mem. iv. 5. 12. *'Εκ τούτου γὰρ γίγνεσθαι ἄνδρας ἀρίστους τε κὰι ἡγεμονικωτάτους κὰι διαλεκτικωτάτους.*

Thus we see how Socrates was the founder of the moral and logical science of the schools of Athens. He taught nothing positively in either branch of philosophy, but he taught men to inquire, and set them on the right track of inquiry. He trained men to think for themselves, to accept no opinion which should be contradicted by the moral and intellectual principles of their own nature, and to rest in no opinion until they had traced it up to these principles.

An exact logic, and a sound ethical system, would in time naturally result from such a direction of men's minds.

In giving account to themselves of their opinions, men would be led to examine into the connexions and dependencies of their ideas. Observations would be made on the relations of ideas, and of words as their signs and representatives. And such observations methodically stated, would at length constitute a system of logic, such as that which Aristotle brought to light about half a century after the death of Socrates. In the mean time, however, the value of ideas in themselves, apart from their expression by words, would engage attention; and a metaphysical logic,—a logic having for its object the determination of the true notion or idea of a thing, and for its business the discussion of the probabilities or appearances of truth surrounding the matter in question,—would naturally be the first to succeed. Such was the Dialectic of Plato,—a science of discourse or discussion, as its name imports; not a particular science, like the logic which grew out of it, but as general in its comprehension as the method itself of Socrates, of which it was the formal development, and equivalent, therefore, to philosophy in the highest sense of that term, as being a search after the nature of things, or, according to him, a theory of Ideas.

Again, in giving account to themselves of their opinions, men would be led to trace the connexion of their moral sentiments and actions with an internal standard of right, independent of the variations of opinion. The examination of this relation would suggest, in process of time, a system of rules for bringing the variable—the sentiments and actions of the individual moral agent—into accordance with the invariable principles of his moral nature. The first ethics, identical, like the first logic, with philosophy in general, would be employed in carrying the views of men to those great principles themselves,—discussing and removing obstructions to the pure contemplation of the nature of virtue. But the more mature study of ethics, taking up the subject as a separate branch of philosophy, would develop the application of the doctrine of the fixed standard, by shewing throughout the field of man's moral nature, how every moral sentiment is strictly limited by its reference to such a standard. The former is the chief business of Plato's ethical philosophy; the latter, that of Aristotle's;—the first tending to a contemplative morality, to a love of the transcendent beauty and excellence of virtue,—the latter, to a theory of active virtue,—to a regulated state of the affections in all the offices of life;—both natural consequences in their order, of that awakening of the reason of men, of which Socrates had been the living instrument.

Socrates, at the same time, by the method which he pursued, taught men the beginning of an art of criticism. From an examination of existing opinions, the transition was natural to the systems of philosophers, and the records of the opinions of men of former days. And, in this respect, Socrates may be regarded as the father of the history of philosophy. Even had the criticism of the writings of philosophers formed no part of his conversations, still he must have prompted such an inquiry by his method of interrogating, and exacting from every one an account of his opinions. But he did more than this. Though not properly erudite, in that sense in which Plato and Aristotle were, he had yet acquainted himself with the doctrines of former philosophers. The chief part of his life was spent with his eye, not on books, but on men. Still, as we are informed by Xenophon, he had read, and had selected, in the course of his reading, whatever he thought valuable in the writings of those before him.[1] Plato, accordingly, has made great part of the conversation of Socrates consist of criticism of the theories of philosophers. Much of this criticism evidently belongs to the richly-various and elaborate learning of the disciple, rather than to the master from whose lips it proceeds. But that Plato is not gratuitously ascribing this kind of learning to Socrates, we see from the manner in which the less erudite disciple refers to the discussions by Socrates of the doctrines of former philosophers. Not only does Xenophon mention, in common with Plato, the comments of Socrates on the more recent system of Anaxagoras,[2] but he refers also to his examination of the great antagonist theories of the older schools, of Parmenides, Xenophanes, Melissus, and others, on the one hand; Heraclitus, Empedocles, and their followers, on the other; though without formally introducing their names.[3]

That various and discordant schools of philosophy should have arisen out of the excitement produced by the energetic call of Socrates to his countrymen, was in the natural course of things. Powerful minds, shaking off the yoke of sloth and indifference, and now at length roused to self-exertion, would, however generally docile to the guidance of a leader, be tempted to try their own powers, and strike out a path for themselves. We are not to wonder, then, that Aristippus, the advocate of pleasure, and Antisthenes, the austere cynic, should have been among the hearers of Socrates, or that Plato should have founded a contemplative mysticism on the sober homely philosophy of his master. Socrates, as we have all along shewn, did not propose any precise system of doctrine to his followers. His mission was accomplished in making them exert themselves. He did not desire that they should think alike, but that all should think and judge for themselves. It is no wonder, therefore, that some should have gone into extravagancies, and that, whilst general good resulted from the excitement, partial evil also should have accompanied it. An Aristippus, or an Antisthenes, could not have issued from the school of Pythagoras. But how much evil generally may have resulted from the abject submission to the authoritative opinions of Pythagoras, in the neglect of self-examination and self-knowledge, and disregard of personal responsibility, by those who implicitly received them?

---

[1] Xenoph. Mem. i. 6. 14. Καὶ τοὺς θησαυροὺς τῶν πάλαι σοφῶν ἀνδρῶν, οὓς ἐκεῖνοι κατελιπον ἐν βιβλίοις γράψαντες, ἀνελιττων κοινῇ συν τοις φιλοις διερχομαι, κ.τ. λ.

[2] Xenoph. Mem. iv. 7.

[3] Ibid. i. 1. 1416.

But whilst we ascribe to Socrates the merit of having given at once the impulse and the character to Grecian philosophy, we must yet single out for special commendation, his admirable services in reviving the forgotten theory of natural religion among his countrymen. Of religion, indeed, as an external system of positive laws enforced by the state, they had, as we have before observed, more than enough. But religion, as a system of truth, was scarcely thought of. When Aristophanes[1] brings on the stage Demosthenes asking Nicias, well-known as Nicias was for his superstitious feeling; *ἐτὲον ἡγεῖ γὰρ θεούς*; "really, then, do you think there are gods?"[2] the allusion is evidently to the real irreligion, which the most rigid and scrupulous worship of the heathen but ill concealed. Resting their belief of a Divine agency in the world on tradition and authority, men omitted to explore the witness of God in their own nature, and in the world around them. Consequently, they were exposed to every objection which the ingenuity of theory, or the folly and wickedness of the world, might suggest to their uninformed credulity, against the positive truth of their religious system. As infidelity in these days finds its refuge in the belief of an infallible church, and is itself in its turn the miserable refuge from the despotism of the very infallibility before which it crouches in silence; so among the votaries of heathen superstition, the doubts and misgivings of the thoughtful intellect, and the troubled heart, were left to prey on themselves, shut up in abject submission to an external authority, and unprepared for their own defence and support. Socrates addressed a great portion of that practical information, which, in spite of his disclaimer of the office of a teacher, he was ever imparting to all around him, to the remedy of this distempered state of the religious feelings. He saw plainly enough that the vulgar theology could not be defended on the ground of rational evidence.[3] This, therefore, in his respect for the ancient laws and customs of his country, he was content to lean on the sanction of positive institution. A great reverence, he justly thought, was due to the wisdom embodied in ancient laws; and he would not encourage persons wantonly to abandon the presumptions of truth and right naturally belonging to established institutions. At least, he would not have men rashly set up their own notions against the presumptions in favour of the wisdom of other men and other days, recommended as these were by some experience of their stability and use, whilst each man's private opinions had no such sanction, or no equivalent sanction. But he felt also, that the internal sense of religion wanted other support,—that presumptions of human vanity and corruption were, and ever would be, brought to bear against this; and that such assaults could only be repelled by a well-informed reason prepared for the encounter. He therefore provided his hearer with a solid and impregnable argument in favour of the being and providence and moral government of the Deity. The argument was what is now familiarly known as the argument from final causes, or the evidences of almighty design in the fabric and course of nature. For this purpose, he gave an induction of instances from the world without, and from the intellectual and moral constitution of man himself, of admirable design in the adaptation of means to ends. He called upon men, with such evidences of divine benevolence around them, not to wait for any more palpable proof, such as judging from the analogy of nature they had no ground to expect, but to believe in the existence of invisible things from their effects, and from the good received to reverence the Deity its author. The language, indeed, attributed to him by Xenophon, is in remarkable correspondence with that of St. Paul, declaring, that "the invisible things of God are clearly seen, being understood by the things that are made, even his eternal power and Godhead;"[4] and the tenor of his argument throughout illustrates the inspired observation of the apostle. More particularly we may advert to his striking inculcation of the doctrine of the moral government of God. He refers to the sense of responsibility as in itself an evidence of the existence of a Divine Power to reward and punish;[5] and he points to the pleasure and pain, advantage and disadvantage, respectively consequent on virtuous and vicious conduct, in the course of things, as instances of a perfection of government beyond the power of human laws.[6] The stock of instances has been enlarged by the researches of modern science, and strength has been added to them by their arrangement and combination. But Socrates, after all, has the distinguished merit of having given the argument from final causes an explicit statement and due importance in the proof of natural religion.

When we think that truths of such high import and interest were sedulously propagated for so many years in the place of concourse of the civilized world, we naturally turn from the contemplation of the living philosopher, to ask, what was the result—what was the amount of beneficial influence on the people to whom his mission was addressed. We cannot doubt, that on the whole the influence was great,—that the serious errors of many in regard to the conduct of life were corrected,—their minds opened to consider the great purposes for which they had been born into the world, and to look for happiness, not from transitory sensual enjoyments, but from the sober and vigorous exertion of their powers of thought and action. In some conspicuous instances, indeed, his endeavours strikingly failed. Critias and Alcibiades were known wherever the name of Athens was heard. And their wild and guilty career presented to the public eye a splendid mirror, from which the most unjust censure was reflected on the philosopher himself. But the many instances which must have occurred in humbler life, of his success in the work of moral reformation, are passed over in silence. That there were such instances Xenophon has given us to understand, when he observes, in his simple manner, that Socrates dismissed those who resorted to him, improved by their intercourse with him.[7] To expect, however, any decisive and permanent public improvement from the teaching of the philosopher, would be to overlook the extent and the malignity of heathen corruption. The men of that day, as of the present, had the voice of God distinctly speaking within them, "their conscience bearing witness, and their thoughts accusing or excusing them," according to that just description of them which Scripture has set before us. But if they shut their ears, and hardened their hearts against this divine instruction, how would they listen to one who was ever upbraiding them with their dulness and inattention to its lessons and admonitions? Rather, they would feel towards him, according to that apposite illustration of Plato, as persons dozing towards one that should wake them up, and, after ridding themselves of his disturbance, think quietly to compose themselves to sleep again.[1] For he did not disguise that his mission to them was one of reproof and expostulation,—a mission, in fact, from the Deity; and that his real concern, accordingly, was not for himself, but for the success of his mission, lest they should incur the guilt of rejecting a divine gift.[2]

---

[1] Aristoph. Eq. 32.

[2] Thucyd. ii. 53, v. 105. *Ἐς τὸ θεῖον νομίσεως*,—and *ἡγούμεθα τὸ θεῖον δόξῃ*,—are expressions of Thucydides, which shew the low ground on which religion was rested in Greece.

[3] Plato, Euthyphro, p. 6. a. *Ἀλλά μοι ἐιπὲ πρὸς φιλίου, σὺ ὡς ἀληθῶς ἡγῇ ταῦτα γεγονεναι ὄυτως*; κ.τ.λ. Op. i. 12.

[4] Xenoph. Mem. iv. 3. 14. *Ἃ χρὴ κατανοοῦντα μὴ καταφρονεῖν τῶν ἀοράτων, ἀλλ' ἐκ τῶν γιγνομένων τὴν δύναμιν ἀυτῶν καταμανθάνοντα τιμᾶν τὸ δαιμόνιον.*

[5] Ibid. i. 4. 16. *Οἴει δ' ἄν τοὺς θεοὺς τôις ἀνθρώποις δόξαν ἐμφῦσαι, ὡς ἱκανοί εἰσιν εὖ καὶ κακῶς ποιεῖν, ἐι μὴ δυνατοὶ ἦσαν*;

[6] Ibid. iv. 4. 24. *Νὴ τὸν Δία, ὦ Σώκρατες, ἔφη, θείοις τâυτα πάντα ἔοικε· τὸ γὰρ τοὺς νόμους αὐτοὺς τοῖς παραβαίνουσι τάς τιμωρίας ἔχειν, βελτίονος ἢ κατ' ἄνθρωπον νομοθέτου δοκεῖ μοι εἶναι.* So Bishop Butier, in his Analogy, part i. ch. 2, observes, "For if civil magistrates could make the sanctions of their laws take place, without interposing at all, after they had passed them, without a trial, and the formalities of an execution; if they were able to make the laws execute themselves, or every offender to execute them upon himself; we should be just in the same sense under their government then, as we are now; but in a much higher degree, and more perfect manner." P. 51.

[7] Xenoph. Mem. i. 2. 61. *βελτίους γὰρ ποιῶν τοὺς συγγιγνομένους ἀπέπεμπεν.* Also ib. 4. 19; iv. 5. 24.

And truly we may regard that energetic call which he was ever sounding in the ears of his countrymen, as a providential warning to the heathen world of the sin and misery of the natural man, trusting to his own imaginations,—how, "changing the truth of God into a lie," he "gives himself over unto lasciviousness, to work all uncleanness with greediness." As God sent his prophets to his chosen people, to tell them of their transgressions, and bid them "remember the law of Moses his servant;" so in his dealings with the nations of the world, He appears to have raised up, from time to time, individuals from among themselves, heathens still, yet gifted with a purity of moral vision beyond their contemporaries, to retrace the divine outline of their fallen nature, amidst its ruins, and to declare almost authoritatively the indelible but forgotten law of right. Israel rejected its prophets; but through all the perverseness of the people, those prophets prepared the way of the Lord. The heathen world, in like manner, refused to listen to its monitors, its legislators, and philosophers; but in spite of their general obduracy and indifference, we cannot but believe that the call was not utterly fruitless. To the original influence of Socrates especially, brought as this was to bear on the great centre of heathen civilization, it may have been in great measure owing, that the light of religious and moral truth was kept alive, however faintly burning, for successive generations, in many a dark abode of superstition; and that in a later day, the doctrine of grace and truth appealed not without effect to the Areopagite of Athens, the jailor of Philippi, and the Roman proconsul at Paphos. He certainly excited a spirit of eager curiosity on moral subjects; as was evidenced in the rise of the schools of philosophy to meet the demands of that spirit, and in the moral character of the disquisitions pursued in them. But this spirit could not have exhausted itself in mere literary discussion. There were doubtless the waverings of anxious minds beyond the precincts of the schools, to be settled; cravings after more safe direction of personal conduct than such as the world around them presented, to be satisfied. Such a state of things would keep men looking for gospel-truth. Some would feel, as Alcibiades is represented by Plato, after a conversation with Socrates, and Euthydemus by Xenophon, at a loss how to pray. And to such the answer of Socrates, as given by Plato, would very indistinctly perhaps, yet not without earnest hope, suggest the high thought, that they must wait until they could be informed by God himself, as to the proper disposition towards God and men; or until one should come to discipline them,—to remove the darkness from their eyes, and enable them to discern both good and evil.[3]

(J. J.)

SOCRATES was also the name of an ecclesiastical historian of the fifth century, born at Constantinople in the beginning of the reign of Theodosius: he professed the law and pleaded at the bar, whence he obtained the name of *Scholasticus*. He wrote an ecclesiastical history from the year 309, when Eusebius ended, down to the year 440; and wrote with great exactness and judgment. His work is to be found in different editions of Eusebius, Sozomenus, and the other Greek writers on the history of the church.

SODA, the name given by the French chemists to the mineral alkali, which is found native in many parts of the world.

SODERAH, a town of the province of Lahore, in the Seik territories, situated on the east side of the Chinaub, forty-eight miles N.N.W. from the city of Lahore. Long. 73. 30. E. Lat. 32. 27. N.

SODOM, formerly a town of Palestine in Asia, famous in Scripture for the wickedness of its inhabitants, and their destruction by fire from heaven on account of that wickedness. The place where it stood is now covered by the waters of the Dead Sea, or the lake Asphaltites.

SODOR, a name always conjoined with Man, in mentioning the bishop of Man's diocese. Concerning the origin and application of this word, very different opinions have been formed by the learned. Buchanan (lib. i. cap. 34.) says, that before his time the name of *Sodor* was given to a town in the isle of Man. In Gough's edition of Camden's Britannia (vol. iii. p. 701.) it is said, that after the isle of Man was annexed to the crown of England, this appellation was given to a small island within musket-shot of Man, in which the cathedral stands, called by the Norwegians the *Holm*, and by the inhabitants the *Peel*. In support of this opinion, a charter is quoted A.D. 1505, in which Thomas earl of Derby and lord of Man, confirms to Huan Hesketh, bishop of Sodor, all the lands, &c. anciently belonging to the bishops of Man. "Ecclesiam cathedralem sancti Germani in *Holm Sodor vel Pele* vocatam, ecclesiam Sancti Patricii ibidem, et locum præfatum in quo ecclesiæ præfatæ sitæ sunt." The truth of either, or perhaps of both, these accounts might be allowed; but neither of them is sufficient to account for the constant conjunction of Sodor and Man, in charters, registers, and histories. If Sodor was a small town or island belonging to Man, it cannot be conceived why it is always mentioned before it, or rather why it should be mentioned at all in speaking of a bishop's diocese. To speak of the bishopric of Sodor and Man in this case, would be as improper as it would be to call the bishopric of Durham the bishopric of Holy Island and Durham, or the bishopric of Darlington and Durham; the former being a small island, and the latter a town belonging to the county and diocese of Durham. Neither of these accounts, therefore, gives a satisfactory explanation of the original conjunction of Sodor and Man.

The island of Iona was the place where the bishop of the Isles resided, the cathedral church of which, it is said, was dedicated to our Saviour, in Greek *Soter*, hence *Sotorenses*, which might be corrupted into *Sodorenses*, a name frequently given by Danish writers to the western isles of Scotland. That we may be the more disposed to accede to this Grecian etymology, the advocates for this opinion tell us, that the name *Icolumkill*, which is often applied to this island, is also of Greek extraction, being derived from *columba*, "a pigeon," a meaning that exactly corresponds to the Celtic word *colum*, and the Hebrew word *iona*. We must confess, however, that we have very little faith in the conjectures of etymologists, and think, that upon no occasion they alone can establish any fact, though, when concurring with facts, they certainly tend to confirm and explain them. It is only from historical facts that we can know to what the name of Sodor was applied.

---

[2] Ibid. Πολλοῦ δεῶ ἐγὼ ὑπὲρ εμαυτοῦ ἀπολογεῖσθαι, ὥς τις ἂν οἴοιτο, ἀλλ᾽ ὑπὲρ ὑμῶν, μὴ ἐξαμάρτητε περὶ τὴν τοῦ θεοῦ δόσιν ὑμῖν, ἐμοῦ καταψηφισάμενοι. P. 71.

[3] Alcib. ii. p. 150, d. Πότε οὖν παρέσται ὁ χρόνος οὗτος, ὦ Σωκράτες; καὶ τίς ὁ παιδεύσων; ἥδιστα γὰρ ἂν μοι δοκῶ ἰδεῖν τόυτον τὸν ἄνθρωπον τίς ἐστιν· Σ. Οὗτος ἐστιν ᾧ μελει περὶ σοῦ, κ.τ.λ. Op. v. p. 160.

It appears from the history of the Orkneys compiled by an old Islandic writer, translated and enlarged by Torfæus, that the Æbudæ, or Western isles of Scotland, were divided into two clusters, Nordureys and Sudereys. The Nordureys, which were separated from the Sudereys by the point of Ardnamurchan, a promontory in Argyleshire, consisted of Muck, Egg, Rum, Canna, Skye, Rasay, Barra, South Uist, North Uist, Benbecula, and Lewis, including Harris, with a great number of small isles. The Sudereys were, Man, Arran, Bute, Cumra, Avon, Gid, Isla, Colonsay, Jura, Scarba, Mull, Iona, Tiree, Coll, Ulva, and other small islands. All these, when joined together, and subject to the same prince, made up the kingdom of Man and the Isles. In the Norwegian language, *Suder* and *Norder* signify southern and northern, and *ey* or *ay* an island. When the Hebrides were under one monarch, the seat of empire was fixed in the Sudereys, and the Nordureys were governed by deputies: hence the former are much oftener mentioned in history than the latter; hence, too, the Sudereys often comprehend the Nordureys, as in our days Scotland is sometimes comprehended under England. Sudereys, or Suder, when Anglicised, became Sodor; and all the Western isles of Scotland being included in one diocese under the Norwegian princes, the bishop appointed to superintend them was called the bishop of Man and the Isles, or the bishop of Sodor and Man. Since Man was conquered by Edward III. it has been separated from the other isles, and its bishops have exercised no jurisdiction over them. Should it now be asked, why then is the bishop of Man still called the bishop of Sodor and Man? we reply, that we have been able to discover no reason; but suppose the appellation to be continued in the same way, as the title king of France was retained by the kings of Great Britain, for several centuries after the English were entirely expelled from France.

SOEST, a city of Prussian Westphalia, in the government of Minden, the capital of a circle of the same name, which extends over 240 square miles, and has a population of 33,400 persons. It is situated on the Tosterbache, and is surrounded with old and lofty walls. In 1834 it had 1200 houses in narrow and crooked streets, and 7854 inhabitants, chiefly occupied in manufactures of various kinds. Lat. 51. 34. 5. Long. 8. 0. 1. E.

SOFALA, or SEPHALA, a kingdom of Africa, lying on the east coast near Zanguebar. The name Sofala denotes, in the Hebrew and Arabic languages, *low country*. It has been celebrated by the Arabian geographers for its golden treasures, but it is from the interior that this precious metal is brought. The soil is fertile, and the climate tolerable. Numberless reefs and banks of sand render the approach dangerous. Long. 35. 40. E. Lat. 20. 20. S.

SOFFITA, or SOFFIT, in *Architecture*, any timber ceiling formed of cross beams of flying cornices, the square compartments or pannels of which are enriched with sculpture, painting, or gilding; such are those in the palaces of Italy, and in the apartments of Luxembourg at Paris.

SOFFITA, or *Soffit*, is also used for the underside or face of an architrave; and more particularly for that of the corona or larmier, which the ancients called *lacunar*, the French *plafond*, and we usually the *drip*. It is enriched with compartments of roses; and in the Doric order has eighteen drops, disposed in three ranks, six in each, placed to the right of the guttæ, at the bottom of the triglyphs.

SOFIA, a city of Turkey in Europe, the ancient Sardica. It is situated in Romelia, and is the capital of a province of its own name. It is on an extensive plain, between the two rivers Iscar and Rissava. It is surrounded with walls flanked by towers, and defended by a citadel. It is the seat of a Greek and of a Catholic bishop; has twenty-three mosques, several Greek, Catholic, and Armenian churches, some Jewish synagogues, 8000 houses, with about 48,000 inhabitants. It is one of the most flourishing cities of the empire, depending chiefly on its manufactures. They consist of silk, woollen and linen goods, and various smaller articles. The general appearance of the town is somewhat imposing; but many of the houses are of wood, and look meanly, as there are few glass windows, and generally iron grating in their stead. Sofia was built by the emperor Justinian out of the ruins of the ancient Sardica, and fell under the power of the Turks in 1382.

SOHAGEPOOR, a town and small district of Hindustan, in the province of Gundwana. The province is situated between the 23° and 24° of N. lat. It is a barren, mountainous, and unproductive country, possessed by various savage chiefs. The town is situated eighty miles S. by E. from Rewah. Long. 81. 45. E. Lat. 23. 29. N.

SOHAM, a town of the hundred of Staplac, in the county of Cambridge, seventy-one miles from London. It is usually called Monks-Soham, to distinguish it from some villages of the same name near it, and from having been formerly the seat of a large Benedictine monastery. It has a charity school and a market on Saturday. The inhabitants were, in 1801, 2004; in 1811, 2386; in 1821, 2856; and in 1831, 3667.

SOHAUL, a town of Hindustan, province of Allahabad, thirty-five miles S.E. from Callinger. Long. 80. 52. E. Lat. 24. 40. N.

SOHNPOOR, a town of the province of Gundwana, in Hindustan, possessed by independent chiefs, situated on the Mahanuddy river, 127 miles S.E. from Ruttunpoor. Long. 83. 45. E. Lat. 20. 47. N.

SOIGNES, a city of the Netherlands, in the province of Hennegan, and arrondisement of Mons. It stands on the river Senne, which rises at the distance of about six miles. The population amounts to 4800 persons, who are chiefly employed in obtaining stone from some valuable quarries. Lat. 50. 32. Long. 3 59. E.

SOIL, the mould covering the surface of the earth, in which vegetables grow. It serves as a support for vegetables, and as a reservoir for receiving and communicating nourishment. See AGRICULTURE.

SOISSONS, an arrondisement of the department of the Aisne in France, which extends over 456 square miles, and is divided into six cantons and 167 communes, containing 68,761 inhabitants. The capital, a city of the same name, is situated in a fine valley on the river Aisne. It has a cathedral with two towers, only one of which has been completed. The town, in 1836, contained 8124 inhabitants, employed chiefly in making linens and leather, and in spinning cotton by machinery.

SOKOR ZOK, a town of Armenia, situated about midway between Bellis and Diarbekir, and governed by a powerful prince, who rules over many different tribes of Kurds and Turcomans. Population, 6000.

SOLANDER'S ISLAND, in the South Pacific, near the south coast of New Zealand, discovered by Captain Cook in 1770. It is of a craggy surface, of great height. Long. 192. 49. W. Lat. 46. 31. S.

SOLDER, SODDER, or *Soder*, a metallic or mineral composition used in soldering or joining together other metals. Solders are made of gold, silver, copper, tin, bismuth, and lead. In the composition there must commonly be some of the metal that is to be soldered mixed with some higher and finer metals. Goldsmiths usually make four kinds of solder, viz. solder of eight, where to seven parts of silver there is one of brass or copper; solder of six, where only a sixth part is copper; solder of four, and solder of three. It is the mixture of copper in the solder that makes raised plate come always cheaper than flat.

SOLDIER, a military man enlisted to serve a prince or state in consideration of a certain daily pay. See ARMY.

SOLDIN, a town of the government of Frankfurt on the Oder in Prussia. It is the capital of a circle of the same name, which extends over 404 square miles, and contains 26,600 inhabitants. The town, which is near the Soldin lake, is surrounded with walls, and contains 434 houses, with 2860 inhabitants.

SOLECISM in *Grammar*, a false manner of speaking, contrary to the rules of grammar, either in respect of declension, conjugation, or syntax. The word is Greek, σολοικισμὸς, derived from the *Soli*, a people of Attica, who being transplanted to Cilicia, lost the purity of their ancient tongue, and became ridiculous to the Athenians for the improprieties into which they fell.

SOLEURE. See SOLOTHURN.

SOLFA, (*Ital.*) a musical exercise for the voice when learning to sing, in which the syllables *do, re, mi, fa, sol, la, si,* are applied to their respective notes in the exercise.

SOLFAING, (Fr. *Solfier*, Ital. *Solfeggiare,*) means the performance of such an exercise; and also the singing of a piece of music at sight with these syllables. On this subject consult the large work on singing, published for the use of the French Conservatory of Music.

SOLFATARA, a lake in the Campagna of Rome, near to Tivoli. It is of small extent, but is remarkable for containing several floating islets formed of matted sedge and herbage, with a soil of dust and sand blown from the adjacent country, and cemented by the bitumen and sulphur with which the water of the lake is impregnated. Some of these islands are more than forty feet long, and will bear five or six persons, who, by means of a pole, may move to different parts of the lake. From this lake there issues a whitish stream, emitting a sulphureous vapour, until it reaches the small river Teverone, which discharges itself into the Tiber. The water of that rivulet is of a petrifying quality, which increases in strength the farther it flows from the lake. Fish are only to be found in the Teverone before it receives this impure stream.

SOLFATERRA, a mountain of Italy in the kingdom of Naples and Terra di Lavorro. This mountain appears evidently to have been a volcano in ancient times; and the soil is yet so hot, that the workmen employed there in making alum need nothing else besides the heat of the ground for evaporating their liquids.

SOLICITOR, a person employed to take care of and manage suits depending in the courts of law or equity. There is also a great officer of the law, next to the attorney-general, who is styled the king or queen's solicitor-general; who holds his office by patent during the sovereign's pleasure, assists the attorney in managing the law business of the crown, and has fees for pleading, besides other fees arising by patents, &c. He attends on the privy-council; and the attorney-general and he were anciently reckoned among the officers of the Exchequer. They have their audience, and come within the bar in all the courts.

SOLID, in *Philosophy*, a body whose parts are so firmly connected together, as not easily to give way or slip from each other; in which sense *solid* stands opposed to *fluid*. Geometricians define a solid to be the third species of magnitude, or that which has three dimensions, viz. length, breadth, and thickness or depth. Solids are commonly divided into regular and irregular. The regular solids are those terminated by regular and equal planes, and are only five in number, viz. the tetrahedron, which consists of four equal triangles; the cube or hexahedron, of six equal squares; the octahedron, of eight equal triangles; the dodecahedron, of twelve; and the icosahedron, of twenty equal triangles. The irregular solids are almost infinite, comprehending all such as do not come under the definition of regular solids; as the sphere, cylinder, cone, parallelogram, prism, parallelopiped, &c.

SOLIDITY, that property of matter, or body, by which it excludes all other bodies from the place which itself possesses; and as it would be absurd to suppose that two bodies could possess one and the same place at the same time, it follows, that the softest bodies are equally solid with the hardest.

Among geometricians, the solidity of a body denotes the quantity or space contained in it, and is called also its solid content. The solidity of a cube, prism, cylinder, or parallelopiped is had by multiplying its basis into its height. The solidity of a pyramid or cone is had by multiplying either the whole base into a third part of the height, or the whole height into a third part of the base.

SOLILOQUY, a reasoning or discourse which a man holds with himself; or, more properly, according to one account, it is a discourse by way of answer to a question which a man proposes to himself.

SOLIMAN II. emperor of the Turks, surnamed the *Magnificent*, was the only son of Selim I., whom he succeeded in 1520. He was educated in a manner very different from the Ottoman princes in general; for he was instructed in the maxims of politics and the secrets of government. He began his reign by restoring those persons their possessions whom his father had unjustly plundered. He re-established the authority of the tribunals, which was almost annihilated, and bestowed the government of provinces upon none but persons of wealth and probity. "I would have my viceroys," he used to say, "resemble those rivers that fertilize the field through which they pass, not those torrents which sweep every thing before them." After concluding a truce with Ishmael Sophy of Persia, and subduing Gozeli Bey, who had raised a rebellion in Syria, he turned his arms against Europe. Belgrade was taken in 1522, and Rhodes fell into his hands the year following, after an obstinate and enthusiastic defence. In 1526 he defeated and slew the king of Hungary in the famous battle of Mohatz. Three years afterwards he conquered Buda, and immediately laid siege to Vienna; but after continuing twenty days before that city, and assaulting it twenty times, he was obliged to retreat with the loss of 80,000 men. Some time after he was defeated by the Persians, and disappointed in his hopes of taking Malta. He succeeded, however, in dispossessing the Genoese of Chio, an island which had belonged to that republic for more than two hundred years. He died at the age of seventy-six, while he was besieging Sigeth, a town in Hungary, on the 30th August 1566.

SOLINGEN, a town of the Prussian government of Cleves, the capital of a circle of the same name. It has been long celebrated for the excellent temper of the sword blades and other cutting instruments fabricated in the town and district. The circle is small, including only forty-two square miles, but it contains 28,500 inhabitants, of whom about four thousand reside within the town. Lat. 51. 12. 31. Long. 7. 2. 20. E.

SOLIS, ANTONIO DE, a Spanish writer, of an ancient and illustrious family, was born at Placentia, in Old Castile, on the 18th of July 1610. He was intended for the law; but his inclination toward poetry prevailed, and he cultivated it with great success. Philip IV. of Spain made him one of his secretaries; and after the king's death, the queen-regent appointed him historiographer of the Indies, a place of great profit and honour. His history of the conquest of Mexico, shows that she could not have named a fitter person. "Historia de la Conquista de Mexico." Madrid, 1684, fol. He is better known by this history, than by his poetry and dramatic writings, though in these he was also distinguished. At the age of fifty-six he took orders. He died at Madrid on the 19th of April 1686.

SOLITARIES, a denomination of nuns of St. Peter of Alcantara, instituted in 1676. The design of the institution was to imitate the severe penitent life of that saint. Thus they were to keep a continual silence; never to open their mouths to a stranger; to employ their time wholly in spiritual exercises, and leave their temporal concerns to a number of maids, who had a particular superior in a separate part of the monastery. They were always to go barefooted, without sandals; gird themselves with a thick cord, and wear no linen.

SOLITARY Island, in the South Pacific ocean, discovered by Mendana in 1595. It is low, and surrounded with rocks. Long. 178. 20. W. Lat. 10. 4. S.

SOLITARY *Islands*, a cluster of small islands near the east coast of New Holland. Lat. 30. 8. S.

SOLO, or SAURA-CORTA, an inland town of Java, the capital of a district, and the residence of an emperor. It is large and populous, intersected with broad and shaded avenues or streets, running at right angles. The emperor's palace is very spacious, and comprises several palaces in its area. The European town and port are very neat. The resident's house is also a large and handsome building. A fine river, which flows near the town, and falls into the harbour of Grepie, affords in the rainy season a ready conveyance for the various productions of a large tract of country, in exchange for commodities which are sent up in boats from the coast.

SOLO, *(Ital.)* a term used in musical compositions of several parts, to mark those voices or instruments that are to perform alone or in a more prominent manner; as, *sofrano solo, violino solo*, &c. The plural is used when two or more voices or instruments of the same name are to perform alone. *Solo* is also a name given to a composition written for a single instrument, such as a violin, an oboe, a flute, &c., which is accompanied by a bass for the violoncello, or a thorough-bass for the pianoforte.

SOLOFRA, a city of Italy, in the Neapolitan province Ulteriore. It contains three churches and 6050 inhabitants, who are manufacturers of gold and silver articles, of leather and parchment, and are celebrated for their salted hams and bacon.

SOLLER, a town in Majorca, one of the Balearic islands in the Mediterranean, belonging to Spain. The valley in which it stands is productive of olives and oranges. It is situated in Lat. 39. 61., and contains 5614 inhabitants.

SOLOMBO, GREAT, a small island in the Eastern seas, of a moderate height. Long. 114. 45. E. Lat. 5. 36. S. Little Solombo is near the north-east coast of Great Solombo.

SOLOMON, the son of David king of Israel, renowned in Scripture for his wisdom, riches, and magnificent temple and other buildings. Towards the end of his life he sullied his former glory by his apostacy from God; from which cause vengeance was denounced against his house and nation. He died about 977 B.C.

SOLOMON'S *Islands*. This group is in the South Pacific ocean, situated chiefly between long. 155° and 160° E. lat. 5° and 12° S. Little is known of the precise situation or number of these islands. The longest are Ysabel, Guadalcanar, San Cristoval, and an island called New Georgia. The first two are affirmed by the Spaniards to be very large islands; the latter nearly seventy miles in extent. Georgia is still larger, and San Cristoval is not less than sixty. These islands were discovered in 1567.

Solon.

SOLON, one of the seven wise men of Greece, was born at Salamis, of Athenian parents, who were descended from Codrus. His father leaving little patrimony, he had recourse to merchandise for his subsistence. He had, however, a greater thirst after knowledge and fame than after riches, and made his mercantile voyages subservient to the increase of his intellectual treasures. He very early cultivated the art of poetry, and applied himself to the study of moral and civil wisdom. When the Athenians, tired out with a long and troublesome war with the Megarensians, for the recovery of the isle of Salamis, prohibited any one, under pain of death, to propose the renewal of their claim to that island, Solon thinking the prohibition dishonourable to the state, and finding many of the younger citizens desirous to revive the war, feigned himself mad, and took care to have the report of his insanity spread through the city. In the mean time he composed an elegy adapted to the state of public affairs, and committed it to memory. Every thing being thus prepared, he sallied forth into the market-place with the kind of cap on his head which was commonly worn by sick persons, and ascending the herald's stand, he delivered, to a numerous crowd, his lamentation for the desertion of Salamis. The verses were heard with general applause; Pisistratus seconded his advice, and urged the people to renew the war. The decree was immediately repealed; the claim to Salamis was resumed; and the conduct of the war was committed to Solon and Pisistratus, who by means of a stratagem defeated the Megarensians and recovered the island.

His popularity was extended through Greece in consequence of a successful alliance which he formed among the states in defence of the temple at Delphi against the Cirrhæans. When dissensions had arisen at Athens between the rich creditors and their poor debtors, Solon was created archon, with the united power of supreme legislator and magistrate. He soon restored harmony between the rich and poor. He cancelled the debts which had proved the occasion of so much oppression; and ordained that in future no creditor should be allowed to seize the body of the debtor for his security. He made a new distribution of the people, instituted new courts of judicature, and framed a judicious code of laws, which afterwards became the basis of the laws of the twelve Tables in Rome. Among his criminal laws are many wise and excellent regulations; but the code is necessarily defective with respect to those principles which must be derived from the knowledge of the true God, and of pure morality, as the certain foundations of national happiness. Two of them in particular were very exceptionable; the permission of a voluntary exile to persons that had been guilty of premeditated murder, and the appointment of a less severe punishment for a rape than for seduction. Those who wish to see accurately stated the comparative excellence of the laws of Moses, of Lycurgus, and Solon, may consult the prize Dissertations relative to natural and revealed religion, published by the Teylerian Society of Haarlem, vol. ix.

The interview which Solon is said to have had with Crœsus king of Lydia; the solid remarks of the sage after surveying the monarch's wealth; the recollection of those remarks by Crœsus when doomed to die, and the noble conduct of Cyrus on that occasion, are known to every schoolboy. Solon died in the island of Cyprus at a very advanced age. Statues were erected to his memory both at Athens and in Salamis. His thirst after knowledge continued to the last: "I grow old," said he, "learning many things." Among the apophthegms and precepts which have been ascribed to Solon, are the following: Laws are like cobwebs, that entangle the weak, but are broken by the strong. He who has learned to obey, will know how to command. In all things let reason be your guide. Diligently contemplate excellent things. In every thing that you do, consider the end.

The chronology of his life is involved in no small obscurity. His legislation may, with some degree of confidence, be referred to the year 594 before Christ; but, as a very learned and able chronologer has remarked, since both his age and the time of his death are doubtful, nothing can be with certainty affirmed of the year of his birth.[1] According to Laertius, he died at the age of eighty; but Lucian extends his life to one hundred years. Of the poems of Solon, an elaborate edition has recently been published by Bach, under the title of "Solonis Atheniensis Carminum quæ supersunt." Bonnæ, 1825, 8vo.

SOLOON, a small island in the Eastern seas, twenty-five miles from the island of Samar. Long. 125. 42. E. Lat. 10. 55. N.

SOLOR Isle, an island in the Eastern seas, separated from the island of Floris by the straits of Floris. It is about thirty miles in length, by fifteen in average breadth.

SOLOTHURN, a canton of Switzerland. It is bounded on the north by France and by Basel, on the east by Basel and Zurich, and on the south and west by Berne. It extends over two hundred and fifty-eight square miles, comprising two cities, one market-town, and one hundred and thirty-seven villages, with 59,122 inhabitants, of whom 54,000 are catholics, and the remainder protestants. The revenues amount to 180,000 francs, and the yearly expenditure to 164,000. It is bound to contribute 904 men, and 1365 francs to the general confederation. The mountains are a continuation of the Jura range, and none of them exceeds 3900 feet in height. The river Aar receives the smaller streams. There are no extensive lakes. The climate is temperate, and the soil produces good corn, hemp, flax, fruit, and wine. The chief employment is agriculture and cutting the extensive woods, which supply some fuel and building timber for exportation.

Solothurn, a city of Switzerland, the capital of the canton of that name. It stands at the foot of the Jura mountains, on both sides of the river Aar. It is surrounded with walls and defended by bastions, is well, but irregularly built, and contains 560 houses, with 4470 inhabitants. It has a college with five professors and a good public library. Solothurn contains several manufactories for making and printing cotton, and some other goods. Lat. 47. 12. Long. 7. 26. E.

SOLOTONOSCHA, a town of Russia, the capital of a circle of the same name, in the province of Pultowa, 947 miles from Petersburg. It stands at the point where the Solontschia falls into the Dneiper. It contains three churches, two monasteries, eight hundred houses, and 5650 inhabitants, chiefly employed in agriculture. Lat. 49. 58. Long. 31. 58. E.

SOLSTICE, in *Astronomy*, the time when the sun is in one of the solstitial points; that is, when he is at his greatest distance from the equator; thus called because he then appears to stand still, and not to change his distance from the equator for some time; an appearance owing to the obliquity of our sphere, and to which those living under the equator are strangers.

The solstices are two in each year; the æstival or summer solstice, and the hyemal or winter solstice. The summer solstice is when the sun seems to describe the tropic of cancer, which is on June 22, when he makes the longest day: the winter solstice is when the sun enters the first degree, or seems to describe the tropic of capricorn, which is on December 22, when he makes the shortest day. This is to be understood as in our northern hemisphere; for in the southern, the sun's entrance into capricorn makes the summer solstice, and that into cancer the winter solstice. The two points of the ecliptic, at which the sun's greatest ascent above the equator, and his descent below it, are terminated, are called the *solstitial points;* and a circle, supposed to pass through the poles of the world and these points, is called the *solstitial colure.* The summer solstitial point is in the beginning of the first degree of cancer, and is called the *æstival* or *summer point;* and the winter solstitial point is in the beginning of the first degree of capricorn, and is called the *winter point.* These two points are diametrically opposite to each other.

SOLYMANIA, called also Shehr Zaur, a town of Kurdistan, the residence of the Pacha. The town had fallen into decay, but was rebuilt by Solyman the Pacha, who, in 1810, having taken up arms against the Pacha of Bagdad, defeated him and put him to death. Population, 6000; fifty-four miles east of Kerkook.

SOMALPET, a town of Hindustan in the Nizam's province of Nandere, fifty-two miles N.N.E. from the town of Nandere.

SOMBOR, or Zombor, a city of the kingdom of Hungary, in the province of the hither Danube, in the circle of Kozep Jaras. It contains 2980 houses, with 14,860 inhabitants, whose chief trade is in corn and cattle. Lat. 48. 8. 32. Long. 21. 10. 33. E.

SOMERS, John Lord, high chancellor of England, was born at Worcester in 1652. He was educated at Oxford, and afterwards entered himself at the Middle-Temple, where he studied the law with great vigour. In 1688 he was one of the counsel for the seven bishops at their trial, and argued with great learning and eloquence against the dispensing power. In the convention which met by the prince of Orange's summons, January 22, 1689, he represented Worcester; and was one of the managers for the House of Commons, at a conference with the House of Lords upon the word *abdicated.* Soon after the accession of William and Mary to the throne, he was appointed solicitor-general, and received the honour of knighthood. In 1692 he was made attorney-general, and in 1693 advanced to the post of lord-keeper of the great seal of England. In 1695 he proposed an expedient to prevent the practice of clipping the coin. In 1697 he was created Lord Somers, baron of Evesham, and made lord high chancellor of England. In the beginning of 1700 he was removed from his post of lord chancellor, and the year after was impeached of high crimes and misdemeanours by the House of Commons, of which he was acquitted upon trial by the House of Lords. He then retired to a studious course of life, and was chosen president of the Royal Society. In 1706 he proposed a bill for the regulation of the law; and the same year was one of the principal managers for the union between England and Scotland. In 1708 he was made lord president of the council; from which post he was removed in 1710, upon the change of the ministry. In the latter end of Queen Anne's reign his lordship grew very infirm in his health; which is supposed to be the reason that he held no other post than a seat at the council-table, after the accession of King George I. He died of an apoplectic fit in 1716. Mr. Addison has drawn his character very beautifully in the Freeholder.

SOMERSETSHIRE, a maritime county of England, lying in a crescent-like form on the Bristol Channel, to which its north-western side is turned. It is bounded to the north-east by Gloucestershire, on the east by Wiltshire, on the south by Dorsetshire and part of Devonshire, and on the west by the latter county. Its greatest length, from east to west, is sixty-five miles, and its greatest breadth, from north to south, forty-five miles. Its boundary line has several considerable indentations. The whole area comprehends 1642 square statute miles, or 1,050,880 English acres; being in extent the seventh in the list of the English counties. The acreable value of the land, according to the late returns under the property-tax, exceeded that of any other county except Leicestershire, being, including the tithes, L.876 per square mile, or about 27s. per acre.

The civil divisions of this county are denominated the eastern and the western. The eastern division contains twenty hundreds and seven liberties, and the western twenty-two hundreds; but these divisions have become of less importance, since other divisions have been politically framed by the Reform act, as will be hereafter noticed. The whole county is in the diocese of Bath and Wells; and is ecclesiastically divided into three archdeaconries, under which are thirteen deans, who superintend 482 parishes. There are within the county two cities (besides a part of Bristol), seven boroughs sending members to Parliament, and twenty-nine market towns.

---

[1] Clinton's Fasti Hellenici, vol. ii. p. 301.

The population of this county at the four decennial periods of enumeration, has been found to be as follows: In 1801, 273,750; in 1811, 303,180; in 1821, 355,314; and in 1831, 402,500.

In 1831, the occupiers of land employing labourers were	6,032
The occupiers of land not employing labourers	3,731
Labourers employed in agriculture	28,107
Labourers in manufactures	4,350
Labourers employed in retail trade or handicraft,	26,672
Capitalists, bankers, &c	4,676
Labourers not agricultural	12,183
Other labourers under twenty years of age	7,074
Males at and above twenty years of age	95,556
Male servants	2,801
Female servants	18,333

In the same year the number of families chiefly employed in agriculture was found to be 30,452; of those chiefly employed in trade, manufactures, and handicraft, 20,230, and of those not comprised in either of the preceding classes, 25,889. The number of inhabited houses was 71,325, occupied by 84,571 families; the uninhabited houses, 3,632, and those building, 939. The annual value of the real property of the county, as assessed in 1813, was L.1,900,651.

The towns whose population in 1831 exceeded 2000, were as follows:

Bath	38,063	North Petherton	3,566
Bedminster, a suburb of Bristol	13,130	Wedmore	3,557
Frome Selwood	12,240	Wivelscombe	3,047
Taunton	11,139	Ilminster	2,957
Bridgewater	7,807	Martoch	2,841
Wells	6,649	Glastonbury	2,500
Yeovil	5,921	Twerton, sub. of Bath	2,478
Shepton-Mallet	5,330	South Petherton	2,294
Chard	5,141	Milverton	2,233
Wellington	4,762	Keynsham	2,142
Bathwick, a suburb of Bath	4,033	Wincanton	2,123
Crewkerne	3,789	Nailsea	2,114
		Milborn Port	2,072
		Bruton	2,031

Few districts contain a greater variety of soil and situation than the county of Somerset. In the north-east corner, the range of the Mendip hills presents a lofty tract of country, of late improved on the surface, but chiefly valuable for the coal and other mines beneath it. On the western side are the Quantock hills, an extensive and sterile range, and beyond them the elevated bleak plain called the forest of Exmoor, the highest district in the western counties. One spot in this forest, called Dunkeny, is 1668 feet above the level of the sea; and from it a prospect over an extended and diversified country is displayed, terminating on one side in the Bristol, and on the other in the English Channel. These hilly, and somewhat barren portions of the county, however, bear but a small proportion to the whole; and between them are to be seen the richest meadows and arable lands, the value of which more than counterbalances the sterility of the hills. In the better parts of the county, it may rather be described as rich than beautiful. There is a deficiency of woods; the streams that run in the valleys are sluggish, and in summer nearly stagnant; but the extent of orchards, especially when in full bloom, produces a pleasing effect, and in some measure compensates for the want of woods.

The rivers of the county are the Avon, which enters it from Wiltshire, and becomes navigable at Bath, which city it nearly surrounds. It then passes, with many curvatures, to Bristol, and soon after is lost in the Severn. The Axe rises in the Mendip hills in two branches, one of which issues from a natural excavation, called Wookey Hole, resembling some of the Derbyshire caverns. Its course is short, and it empties itself through some marshes, below Axbridge, into the Bristol Channel. The Brue rises in Wiltshire, and also enters the Bristol Channel, being navigable not more than two miles from its mouth. The Parret rises at a village of the same name in Dorsetshire, becomes navigable at Langport, and in rainy seasons a few miles above that town. It is joined, at Boroughbridge, by the Thone or Tone, which proceeds from Taunton, and passing by Bridgewater, empties itself into the sea. The only navigable canal that has been completed is the Kennet and Avon, which unites together the two great rivers Thames and Severn. It commences near Bath, and soon enters Wiltshire. Other canals have been projected in different directions, but none of them has been prosecuted to completion; though on several of them large sums have been expended.

As Somersetshire contains, on the banks of its rivers, large tracts of the richest meadow lands, the most valuable branch of its rural economy is the fattening of cattle and the management of the numerous dairies. The oxen, bred chiefly in the less fertile pastures of Devonshire, when grazed in this county, afford the best beef, and furnish, in great numbers, the markets of the metropolis, as well as those of Bristol and Bath, in their immediate vicinity. The produce of the dairy is of the best kind. The cheese of Cheddar has obtained great celebrity, but that made in many other parts, and frequently sold as Gloucester, is equal to any in the world. The butter in the southern division of the county is excellent, and much of it, collected in the vicinity of Crewkerne, is sent to the London cheesemongers, who supply it to their customers under the denomination of Dorsetshire butter.

The next agricultural product is cider, which forms almost the universal beverage of the working classes. It is a more pure and yet a stronger liquor than the cider either of Herefordshire or Devonshire. The consumption of it within the county is very large, and some is sent to distant parts. Nature has been so bountiful in furnishing spontaneous productions, that to those agricultural pursuits which depend on skill and industry less attention is paid in this than in many other districts. Such is the abundance of natural grass, that the farmers do not find it necessary to grow a crop of clover, or other artificial grass, so uniformly between two corn crops as is necessary in other counties; nor is the practice of fallowing, or of introducing a rotation by commencing with turnips, much resorted to. Notwithstanding this, they grow good crops of corn, and in the hundred of Taunton Dean the wheat is of the very best quality. Barley is not very extensively cultivated, as the general use of cider causes but little consumption of malt. The barley crops are in general very good. Oats are extensively cultivated, but scarcely equal the demands of the county, and the easy intercourse with Ireland readily supplies any deficiency when it occurs. The soil is well calculated for the growth of flax, and it furnishes a large proportion of that used in the manufactures of the county. It is not unusual to rent land for half a year while a crop of flax is raised; after which it is taken again by the regular occupant, who finds the flax to be an excellent preparative for wheat, from the careful weeding necessary to its growth.

The rich loamy soil brings to maturity the best elm timber. Goose feathers were formerly produced in great abundance; but the draining and inclosing many of the richest marshy plains has rendered these capable of yielding more profit by other productions, and of late years the quantity of feathers is much diminished. The landed property of the county is much divided, no one proprietor or great family having such extensive possessions as to give a preponderant political influence. There is a great number of yeomen who share the lands, and many of them maintain the homely independence of the past generations.

The mineral products of this county are valuable. The hills of Mendip supply with coals their vicinity, the cities of Bath and Wells, and the towns of Frome and Shepton-Mallet. The other parts of the county use the coals of Newport, which are brought by sea to Bridgewater. Lead, of a quality superior to that of Derbyshire, is found in Mendip and on the Cheddar hills. Calamine is extensively produced, and supplies the brass manufacturers of Bristol. Copper is found near Stowey. Manganese, bole, and red ochre, are among the other products of Mendip.

This is a manufacturing district for various productions. The manufacture of fine woollen cloth is extensive, chiefly at Frome, where it employs 730 males upwards of twenty years of age; and at Road are employed 59, at Beckington 32, Charter Henton, 24, Twerton, near Bath, 284, Lyncombe and Wedcombe, 565, and at Freshford, 32 makers of fine cloths. In another part of the county, at Wellington and Milverton, are nearly 300 makers of cloth of an inferior description. About 300 men are employed in making sail-cloth, sacking, and girth-web, at Crewkerne and the parishes of East Coker, Merriot, West Hatch, and North Perrot. At Chard 478 men, and at Ilminston 21, are occupied in making silk and lace, or the machinery for those fabrics; and the same trades afford considerable occupation at Bruton and Taunton. At Yeovil, and some of the towns and villages near it, the chief trade is glove-making, which gives employment to more than 600 men, and a great number of females. Edge tools are made at Wells, employing 60 men, and also at Whately, Emborrow, and some other places. At Nailsea, 100 men are employed in the manufacture of glass; paper-making and tanning occupy 59 men at Cheddar; and at various places in the county are noticed manufactures of iron, calamine, copper, brass, paper, and snuff; and a variety of small articles is made at Bath.

The foreign commerce of Somersetshire passes chiefly through Bristol, which is the mart for such goods as are required in distant countries. Some of the woollen goods which are manufactured at Taunton and Wellington are shipped from Exeter. The far greater portion of the productions of the county are, however, destined to supply the demand for internal consumption. The cattle, butter, and cheese, are chiefly sent to London, and in time of war, to Portsmouth and Plymouth. The linen and woollen goods are distributed through the western and Welsh counties, and, in general, are destined more for the home than for foreign markets.

The titles derived from this county are those of the dukes of Somerset and Wellington; the marquises of Lansdowne, Bath, and Bristol; the earls of Bridgewater, Poulet, and Ilchester; and the barons Mendip and Glastonbury. By the reform bill the county has been politically formed into two divisions, the eastern and the western, and each division elects two members to the house of commons. The election for the first is held at Wells; and the other polling places are Bath, Shepton-Mallet, Bedminster, Axbridge, and Wincanton. The election for the second is held at Taunton; and the other polling places are Bridgewater, Ilchester, Williton, and Langport.

The seats of the nobility and gentry, especially of the latter, near Bath and Bristol, are numerous; and our limits allow only of noticing the most distinguished of them, viz. Longleet, the seat of the Marquis of Bath; Hinton, the seat of Earl Poulet; and the houses of the Earl of Carnarvon, Lord Hood, Mr. Miles, and Colonel Gore Langton.

Two members are chosen for each of the cities of Bath and Wells, and two for each of the boroughs, Taunton and Bridgewater. The boroughs of Minehead, Ilchester, and Milburn-Port, which chose two members each, have been disfranchised, and the town of Frome has been made a parliamentary borough, returning one member. Ilchester, from the elections being held there, and from its containing the gaol and county court, is usually considered the county town, although the assizes in the spring are held at Taunton, and in the summer at Wells and Bridgewater alternately.

SOMERTON, a town in the hundred of that name in the county of Somerset, 125 miles from London. It is pleasantly situated in a fertile country. The inhabitants were in 1801, 1145; in 1811, 1478; in 1821, 1643; and in 1831, 1786.

SOMMEANY, a town of Persia, in the province of Mekram, and the principal sea-port of Lus. It is situated on an elevated bank, at the mouth of the river Pooralee, which forms a bar about a mile from the town, with three fathoms depth at low water, and boats can anchor close to the shore. It is an inconsiderable place, and the inhabitants, with the exception of a few Hindu merchants, subsist by fishing.

SOMMEE, a town of Hindustan, in the province of Gujrat. It is a large place, but has a wretched appearance, and the wall by which it is surrounded is in many parts falling to pieces. It stands in a swamp, and is surrounded by numerous puddles, and in the rainy season is almost under water. It is situated to the south-east of Rahdunpoor.

SOMME, a department of the north of France. It has been formed out of those parts of the ancient Picardy known as Amienois, Ponthieu, Vimieux, and Santerre, and extends over 1,460,932 acres, or 2284 square miles. It is bounded on the north by the Pas de Calais; on the east by the departments of the North and of the Aisne; on the south by the Oise and the Lower Seine; and on the west by the British channel. It contains five arrondisements, with forty-one cantons, and 835 communes, and its population in 1836 amounted to 552,706. The surface is flat and level, but gradually slopes towards the sea on the western side. There are no mountains, but some hills of inconsiderable height rise on the eastern frontier. The Somme, which has its source in the department of the Aisne, is the chief river. The others are the Avre, the Noye, the Celle, and the Brisle. The soil is chalky, and naturally fruitful. The inhabitants cultivate to a great extent corn and hemp, and considerable quantities of corn are exported. Cattle and sheep are reared in large flocks. The country is almost destitute of wood, but the valleys abound in peat. The wine produced is small in quantity, and inferior in quality. Oleaginous seeds are extensively cultivated for the manufacture of oil. In this district are numerous and extensive establishments for the manufacture of woollen cloths and fine linen goods, such as cambrics, lenos, and lawns, carpets, hats, hosiery, leather, soap, cutlery, and other hardware. It is, on the whole, one of the most prosperous divisions of the kingdom, and contains, besides many towns and villages densely inhabited, the large cities Amiens (population, 46,129) and Abbeville, (population, 18,247), in which most of the commerce of the department is concentrated.

SOMNAMBULISM, or Sleep-walking. According to a report made to the Physical Society of Lausanne, by a committee appointed to examine a young man who was accustomed to walk in his sleep, the disposition to this singular habit seems to depend on a particular affection of the nerves, which both seizes and quits the patient during sleep. Under the influence of this affection, the imagination represents to him the objects which strike him while awake, with as much force as if they really affected his senses; but it does not make him perceive any of those which are actually presented to his senses, except in so far as they are connected with the dreams which engross him at the time.

If during this state the imagination has no determined purpose, he receives the impression of objects as if he were awake; only, however, when the imagination is excited to lend its attention towards them. The perceptions obtained in this state are very accurate; and when once received, the imagination renews them occasionally with as much force as if they were again acquired by means of the senses. But the impressions received during this state of the senses disappear entirely when the person awakes, and do not return till the return of the same disposition in the nervous system.

The remarks of this committee were made on a lad named Devaud, who was thirteen years and a half old, and who lived in the town of Vevey. He possessed a robust constitution; but his nervous system appeared to be organized with peculiar delicacy, and to discover marks of the greatest sensibility and irritability. His senses of smell, taste, and touch, were exquisite: he was subject to fits of immoderate and involuntary laughter; and he sometimes wept without any apparent cause. His sleep was at all times unquiet, but particularly when the fits were about to seize him. During his sleep, motions were observable in every part of his body, with starting and palpitations; he uttered broken words, sometimes sat up in his bed and lay down again. He then began to pronounce words more distinctly, and rising abruptly, acted as he was instigated by the dream which then possessed him.

From the facts which were brought under the observation of this committee, they inferred that the functions of the somnambulist, while under the influence of this affection, are not suspended, as to what he wishes to see, or the objects about which his imagination is occupied; that he may also be disposed to receive those impressions when his imagination has no other object at the time; that in order to see, he is obliged to open his eyes as much as he can, but when the impression is once made it remains; that objects may strike his sight without striking his imagination, if it is not interested in them; and that he is sometimes informed of the presence of objects without either seeing or touching them.

A great number of similar instances might very easily be accumulated. Such anomalous operations of the mind it is perhaps beyond the power of philosophy to explain; but a very small portion of philosophy, or even common sense, will enable us to dispose of another class of vagaries imputed to animal magnetism. The magnetisers are a sort of conjurers, who, according to their own account, are able to superinduce a state of sleep, and, while their patients are in that state, to exercise a marvellous influence over their volitions. Deleuze, in his *Histoire Critique du Magnétisme Animal*, furnishes these very edifying details: "When magnetism produces somnambulism, the being who finds himself in this state acquires a prodigious extension in the sense of feeling. Several of his exterior organs, usually those of sight and hearing, are rendered torpid, and all the sensations which depend on them are internally performed. There is in this state an infinite number of shades and varieties; but in order to form a correct judgment, it must be examined in its greatest remoteness from the state of waking, passing over in silence every thing that experience has not established. The somnambulist has his eyes closed, and does not see by the eyes nor hear by the ears; but he sees and hears better than a waking man. He sees and hears only those with whom he is in relation. He sees only that which he looks at, and he usually looks only at those objects to which his attention is directed. He is subject to the will of his magnetiser for every thing that cannot harm him, and for every thing that is not opposed to his ideas of justice and truth. He feels the will of his magnetiser; he perceives the magnetic fluid; he sees, or rather he feels, the interior of his own body, and those of others; but he usually remarks only the parts which are not in the natural state, and which disturb the harmony of the economy; he retraces in his memory the remembrance of things which he had forgotten while awake; he has pre-visions and pre-sensations, which may be erroneous in several circumstances, and which are limited in their extent; he expresses himself with a surprising facility; he is not exempt from vanity; he improves of himself, for a certain length of time, if he is wisely managed; he spoils if he is ill directed. When he re-enters into the natural state, he absolutely loses the recollection of all sensations, and of all ideas which he has had in the state of somnambulism; so that these two states are as unconnected with one another, as if the somnambulist and the waking man were two different beings." The simple enunciation of such absurdities as these, seems to preclude the necessity of all formal discussion.

In addition to their other attributes, some of the magnetic somnambulists are endowed with a miraculous skill in physic. "Those patients in crisis," says Cloquet, "who are named physicians, have a supernatural power, by which, on touching a patient who is presented to them, on carrying the hand even above the clothes, they feel what is the affected organ, the suffering part; they declare it, and mention nearly the suitable remedies. A singularity not less remarkable than all those which I have enumerated is, that those physicians who for several hours have touched patients, and have reasoned with them, remember nothing, absolutely nothing, when the master pleases to disenchant them, and to restore them to their natural state. The time which has elapsed from their entrance into the crisis to their coming out of it, is, so to speak, annihilated to such a degree, that if a covered table be presented to these sleeping physicians, they will eat and drink; and if, the table being uncovered, the master restores them to their natural state, they will have no recollection of having done so. The master has the power not only, as I have already said, to make himself be understood by these physicians in crisis, but I have repeatedly seen him present from a distance his finger to one of these physicians, always in crisis, and in a state of spasmodic sleep, make him to follow him where he pleased, or send him to a distance from himself, either to his house or to different places, which he mentally indicated without telling him."

Another phenomenon, equally worthy of admiration, is the power of reading without the aid of eyes. Pigeaire, a physician of Montpellier, is answerable for the following statement of his daughter's performances in this new department. "We made her read with her eyes closed by magnetic sleep, or covered with a handkerchief in the form of a bandage; she read with the greatest facility characters printed or written, not only in applying her fingers to the paper, but also with a plate of glass interposed between the book and her fingers. More than forty persons have been witnesses of this experiment, which we took care to perform before only a few persons at a time, in order not to disturb the little somnambulist. This experiment has never failed; once only it has been incomplete. The little girl, in the state of somnambulism, named certain objects enclosed in snuff-boxes; announced persons previously to their entrance into the room in which she was; and several times mentioned the hour and the minute on a hunting watch which she held in her hand." Those who are acquainted with the waking performances of Miss Macavoy of Liverpool, will experience no difficulty in understanding the sleeping performances of Miss Pigeaire of Montpellier.

SOMNER, William, an eminent English antiquary, was born at Canterbury in 1606. His first treatise was the Antiquities of Canterbury, which he dedicated to Archbishop Laud. He then applied himself to the study of the Saxon language; and having made himself master of it, he perceived that the old glossary prefixed to Sir Roger Twisden's edition of the laws of King Henry I. printed in 1644, was faulty in many places; he therefore added to that edition notes and observations valuable for their learning, with a very useful glossary. His Treatise of Gavelkind was finished about 1648, though not published till 1660. Somner was zealously attached to King Charles I.; and in 1648 he published a poem on his sufferings and death. His skill in the Saxon tongue led him to inquire into most of the European languages, ancient and modern. He assisted Dugdale and Dodsworth in compiling the *Monasticon Anglicanum*. His Saxon Dictionary was printed at Oxford in 1659. He died in 1669.

SOMPRE, a town of Hindustan, in the province of Cashmere, situated on the east side of the Jhylum river. Long. 73. 25. E. Lat. 34. 17. N.

SONATA (*Ital.*), a piece of music, consisting of various movements for a single instrument, with or without accompaniment. The name has sometimes been given to certain vocal compositions, in which all the voices are equally essential. Some of the most remarkable modern sonatas are for the pianoforte, such as those of Haydn, Mozart, Beethoven, Clementi, Dussek, &c. Formerly sonatas were classed as *sonate di camera* and *sonate di chiesa*, i. e. *chamber-sonatas* and *church-sonatas*, on account of their difference of style, and the place of performance.

SONATINA (*Ital.*), a short and easy sonata.

SONDERHAUSEN, the capital of the principality of Schwartzburg-Sonderhausen, in Germany, stands on the river Wipper, at the junction of the Bebra with that stream. It is well built, and the castle on which the prince resides is situated on a hill overlooking the city; it is a venerable object, with some pleasing promenades near to it. The city contains a gymnasium, two churches, and an orphan-house, 460 dwellings, and 3600 inhabitants. Long. 10. 45. 1. E. Lat. 51. 22. 33. N.

SONDRE Grund, or Bottomless, an island in the South Pacific Ocean, discovered by La Maire and Schouten in 1616. It is about twenty leagues in circumference. Long. 148. W. Lat. 15. S.

SONDRIO, a delegation of the Austrian kingdom of Lombardy, extending over 1139 square miles, is bounded on the north by Switzerland, on the east by the Tyrol, on the south by Bergamo, on the south-west by Como, and on the west by Switzerland. It comprehends an extensive valley, with lofty mountains on both sides, sometimes called the Valteline. It contains one city, six towns, and seventy-eight villages, with 91,600 inhabitants. The capital is a city of the same name, situated at the entrance of the valley, on the river Moller. It contains 3480 inhabitants.

SONEHUT, a small town and mud-fort of Hindustan, in the province of Gundwana. Long. 82. 33. E. Lat. 23. 33. N.

SONEPOUR, a town of Hindustan, in the province of Orissa, situated on the west bank of the Mahanuddy, at its confluence with the Taile river. Long. 83. 30. E. Lat. 20. 47. N.

SONG, in *Music*, in a general sense, applies to melody, whether vocal or instrumental. It is usually applied to an air adapted to the words of a short poem. Sometimes, with an adjunct, it means a particular form of melody, as *plain song* (Fr. *plain chant;* Ital. *canto piano*, or *canto fermo*). Among songs, the most characteristic and interesting are the national ones of various countries. To the influence of national song may be traced those remarkable changes and improvements in the style of melody, with regard to freedom and expression, that are so perceptible in the music of professed composers within the last two centuries.

Song of Birds. See Singing, and Philosophical Transactions, vol. lxiii.

SONGHUR, a town of Hindustan, in the Gujerat peninsula, situated in a wild country, twenty-five miles north-west from Wankaneer. Near it is a very ancient temple dedicated to the sun, and adorned with a variety of sculptures, in a style greatly superior to any modern works by the Hindus. In the interior of this temple is a male figure, three feet high, with uplifted hands, each holding an image of the sun; and on his two sides are two smaller idols of the same kind. There are also two other temples, one of which contains the figure of Bhavani standing on an animal resembling a tortoise, and surrounded by female attendants. There is no record concerning the time when these temples were built.

SONGI, a small river on the eastern coast of Malacca, falls into the China Sea. Lat. 2. 10. N.

SONGKIANG, a city of China, of the first rank, in the province of Kiangnan. It is situated on the great canal, very conveniently for trade, which is carried on to a considerable extent in calicoes and other cotton cloths. It has four large cities under its jurisdiction. It is 560 miles south of Pekin. Long. 120. 44. E. Lat. 31. N.

SONG-MEN-CHAN, a small island near the coast of the province Tchekiang, in China. Long. 121. 21. E. Lat. 31. N.

SONGOA, an island in the Straits of Malacca. It is about fifty miles in circumference. Long. 100. 30. E. Lat. 2. 18. N.

SOOLOO Isles. These isles, about sixty in number, derive their name from Sooloo, the principal island in the group. They form a chain which extends in a north-east and south-west direction, from the north-eastern extremity of Borneo to the western extremity of Magindanao, and from the 4th to the 7th degrees of north latitude. The island of Sooloo is about thirty miles in length by twelve in average breadth, and contains 60,000 inhabitants. It lies midway between the islands of Borneo and Magindanao, is well cultivated, and affords a fine prospect from the sea; nor has it any certain rainy seasons, like the other Malay islands. This is owing to the moderate height of the hills not intercepting the clouds in their passage from the sea. Most rain falls, however, during the south-west monsoon, and also at the change of the monsoon, especially the autumnal. But these changes are not followed by any storms, and very seldom at any other time, so that the island enjoys almost a perpetual summer. There are several good harbours among these islands, particularly at Bewabewa, Tavitave, Tappool, Secassee, between Boobooan and Tappeantana, south of Basselan. The harbour of Bewan, the capital of Sooloo, is not good, except during the south-west monsoon. This place is situated on the sea-coast, on the north-west part of the island, and is of considerable size. The houses are built after the manner of the Malays, elevated about four feet from the ground with bamboos, of which the floors also are made. The island of Sooloo being small in proportion to its population, habits of industry prevail, and great attention is paid to agriculture. Rice is planted; but it is a precarious crop, owing to the uncertainty of the rains. Many roots are in consequence cultivated in its stead, namely, the Spanish or sweet potatoe, and yams of different species. They have abundance and variety of every species of tropical fruit. The oranges are equal in quality to those in China: they have also a fruit called jack or nanka, durians, a kind of large custard apple, called madang, mangoes, mangustines, rambustines, and a fruit they call bolona, like a large plum or mangoe, white inside. The trees in the woods are loaded with fruits, which ripen well, and are not injured by too much moisture. The Sooloos, from the great number of the Chinese that are among them, have learned from them the art of gardening; and they ingraft and improve their fruits.

Wild elephants are to be found in the woods; which is a remarkable circumstance, considering that the island is small and populous. Spotted deer, goats, and black cattle, are also abundant. Wild hogs abound, and do much mischief; but the natives have few sheep. They have, however, a good breed of horses, which are trained to trot, but not to gallop. After harvest the inhabitants hunt both the elephants and the wild hogs, with a view to destroy them.

The island of Sooloo was formerly the centre of an extensive trade, and was frequented by ships from Japan, which imported silver, amber, silks, chests, cabinets, and other curiosities made of fragrant woods, besides great quantities of silks and porcelain from China. It was also visited by vessels from Java, Sumatra, Ceylon, and the coast of Coromandel, with valuable cargoes. This trade has greatly declined. The intercourse with China is now confined to two junks, which arrive annually from Amoy with cargoes of brass salvers, iron, sugar-candy, raw silk, black nankeen, white linen of a strong fabric, china ware, flowered silks, besides tea, cutlery and other hard ware, brass wire, gongs, beads of all colours, little swan-shot, fire-works, &c. In return they export to China biche de mer, black and white wax, pearl-oyster shells, bird-nests, and tortoise-shell; also a sea-weed used as gum or glue, and other articles, such as Carooang oil, clove-bark, black wood, ratans, sago, various barks for dyeing, cassia, pepper, native camphire, sandal-wood, curious shells for grottoes, pearls, and spices. These islands are also occasionally visited by country ships, which import articles of European manufacture, such as brasiery, cutlery, cloth, gunpowder, fire-arms, manufactures in glass, iron, opium, piece-goods, saltpetre, shot, swords, tin ware, watches, sugar, tobacco, &c. From Borneo are imported sago, biche de mer, cowries, and tortoise-shell. Rice is imported from Magindanao, and is paid for with Chinese goods. Cotton manufactures from Celebes complete the list of imports. There is a famous pearl-fishery at Sooloo and the neighbouring islands.

These islands are governed by a hereditary prince or sultan, whose power is, however, counterbalanced by the nobles. The Sooloos seldom venture from home in their own vessels, except for the purpose of predatory excursions to make slaves among the Philippine Islands. They are warlike in their habits, though they depend less on fire-arms than on the lance, sword, and dagger, in the use of which they are very dexterous. The inhabitants have reached a higher stage of civilization than is generally attained in the Asiatic islands. The women are not strictly confined, as in many Mahommedan countries. In their houses are domesticated many Philippine and some Spanish slaves, who are purchased from the Illanos and Magindanese cruisers. Notwithstanding their boasted civilization, murder is a crime extremely common among them, and occurs on the least provocation. In 1800 they treacherously assassinated the captain of a country ship, and his boat's crew; and afterwards made an attack on the ship, but were repulsed.

Of the early history of these islanders little is known. They assert, that they once formed a part of an ancient Bornean empire, founded by the Chinese. But the Magindanese assert that they were formerly subject to them. From the period when the Spaniards obtained possession of the Philippines, they have been engaged in a constant warfare with the Sooloos, but with little advantage to themselves, being always repelled in their attempts to obtain possession of these islands.

SOONDA, a town and district of Hindustan, in the province of North Canara. The district, which is small, is situated between the 14th and 15th degrees of north latitude, above the Western Ghauts. Formerly the country was well cultivated, and produced fine timber and pepper, betel nut, cardamoms, and plantains. Towards the eastern division of the country, the great object of agriculture is rice. Having been the seat of war between Hyder and the Mahrattas, it was greatly wasted by the former in 1763, and its rajah compelled to fly for protection to Goa; on which occasion he surrendered the whole of his territory below the Ghauts for a stipulated pension. In 1799 the Soonda district became the property of the British, with whom it remains. The capital, of the same name, was formerly an extensive and populous town, and was defended by strong fortifications, which were levelled by Hyder, who also nearly destroyed the town. Long. 74. 58. E. Lat. 14. 34. N.

SOONDIA, a town of Hindustan, in the province of Sinde, situated on the Indus, on the route from Tatta to Hyderabad. Lat. 24. 58. N.

SOONEL, a town of Hindustan, in the province of Malwah, belonging to the Mahrattas, 60 miles south by east from Kotah. It is regularly built, with streets at right angles, and is of considerable extent. Long. 76. 5. E. Lat. 24. 21. N.

SOONERGONG, or SUNERGONG, a town of Bengal, situated on one of the branches of the Brahmapootra. It was once a large city, the provincial capital of the eastern division of Bengal, and famous for its manufactures of muslin and other fine cottons. It is now reduced to a mere village, principally inhabited by weavers, and the city of Dacca has risen on its downfall. Long. 90. 43. E. Lat. 23. 39. N.

SOONGUR, a town of Hindustan, in the province of Gujerat, 39 miles east by south from Surat. Long. 73. 38. E. Lat. 21. 8. N.

SOONPUT, a small town of Hindustan, in the province of Delhi. To the north is a handsome mausoleum of Khizer Khan, an Afghan nobleman of the family of Shere Shah. The adjacent country was greatly benefited by the canal dug by Aly Merdan Khan. Orders have been given by the British government to repair the canal, which will aid the country to recover from the desolate state in which it has been for some years past. Long. 76. 53. E. Lat. 29. N.

SOONTABURDAR, in the East Indies, an attendant, who carries a silver bludgeon in his hand, about two or three feet long, and runs before the palanquin. He is inferior to the chubdar; the propriety of an Indian newaury requiring two soontaburdars for every chubdar in the train. The chubdar proclaims the approach of visitors, &c. He generally carries a large silver staff about five feet long in his hands; and among the nabobs he proclaims their praises aloud as he runs before their palanquins.

SOOPOOR, a town of Hindustan, in the Rajpoot territories, province of Ajmeer. It is the capital of a small principality, and is 65 miles north-east from Kotah. Long. 76. 45. E. Lat. 25. 43. N.

SOOROOTOO ISLE, a small island in the Eastern Seas, situated off the western coast of Borneo, and separated from the island of Carimatia by a narrow strait, through which a ship might run if compelled by necessity. Long. 108. 40. E. Lat. 1. 45. S.

SOOROPOOR, a town of Hindustan, in the province of Bejapoor, situated on the Krishna river, nearly 130 miles south-west from Hyderabad. Long. 77. E. Lat. 16. 15. N.

SOORY, a town of Bengal, district of Birbhoom, 50 miles south-west from Moorshedabad. Long. 87. 32. E. Lat. 23. 54. N.

SOOSNEER, a considerable town of Hindustan, in the province of Malwah, 57 miles north-north-east from Oojain. Long. 76. 10. E. Lat. 23. 55. N.

SOOSOO, a small town on the west coast of Sumatra, where pepper is sometimes exchanged for gold dust. Long. 97. 10. E. Lat. 3. 45. N.

SOOSOOHOONAN, a district in the island of Java, on the south coast, formerly extending to the north coast, and including the territories of Cheribon, and the greater part of the island. It is now much fallen from its ancient grandeur, and in the last century was divided into two parts. The prince, embarrassed by the rebellion of a powerful nobleman, made a cession of his territory to the Dutch, who in return granted him half back again, under the title of Sultan. Prior to 1740 this sovereign was proprietor of all the territory to the east of Cheribon; but he lost part of his dominions in a new contest with the Dutch. The dynasty, however, still continues; and in 1813 the capital was visited by Sir Stamford Raffles, the British governor, who was graciously received.

SOOT, a volatile matter arising from wood and other fuel along with the smoke; or rather it is the smoke itself condensed, and gathered to the sides of the chimney. Though once volatile, however, soot cannot be again resolved into vapour, but, if distilled by a strong fire, yields a volatile alkali and empyreumatic oil, a considerable quantity of fixed matter remaining at the bottom of the distilling vessel. If burnt in an open fire, it flames with a thick smoke, whence other soot is produced. It is used as a material for making sal ammoniac, and as a manure.

SOOTY, a town of Bengal, in the province of Raujeshy, where an action was fought in 1763, between the British troops and those of Meer Cossim, in which the latter were defeated. Long. 88. 2. E. Lat. 24. 36. N.

SOPHI, or SOFI, a title given to the emperor of Persia, importing as much as wise, sage, or philosopher.

SOPHIS, or SOFEES, a kind of religious order among the Mahommedans in Persia, answering to what are otherwise called *dervises*, and among the Arabs and Indians *faquirs*. Some writers suppose them to be called sophis from a kind of coarse camblet which they wear, called *souf*, from the city Souf in Syria, where it is principally manufactured. The more eminent of those sophis are complimented with the title *schiek*, that is, *reverend*, much as, in Romish countries, the religious are called *reverend fathers*. Schiek Sophi, who laid the foundation of the grandeur of the royal house of Persia, was the founder, or rather the restorer, of this order. Ishmael, who conquered Persia, was himself a sophi, and greatly valued himself on that character. He chose all the guards of his person from among the religious of this order, and would have all the great lords of his court sophis. The king of Persia is still grandmaster of the order, and men of rank continue to enter into it, though it be now fallen under some contempt.

SOPHISM, in *Logic*, a specious argument, having the appearance of truth, but leading to falsehood. Sophisms are reduced by Aristotle into eight classes, an arrangement so just and comprehensive, that it is equally proper in present as in former times. 1. *Ignoratio elenchi*, in which the sophist seems to determine the question, while he does it only in appearance. Thus the question, Whether the excess of wine be hurtful? seems to be determined by proving, that wine revives the spirits and gives a man courage; but the principal point is here kept out of sight, for still it may be hurtful to health, to fortune, and reputation. 2. *Petitio principii*, a begging of the question, or taking for granted that which remains to be proved; as if any one should undertake to prove that the soul is extended through all the parts of the body, because it resides in every member. This is affirming the same thing in different words. 3. Reasoning in a circle; as when the Romanists prove the Scriptures to be the word of God by the authority of the church, and the authority of the church from the Scriptures. 4. *Non causa pro causa*, or the assigning of a false cause to any effect. Thus the supposed principle, that nature abhors a vacuum, was applied to explain the rising of water in a pump, before Galileo discovered that it was owing to the pressure of the atmosphere. In this way the vulgar ascribe accidents to divine vengeance; and the heresies and infidelity of modern times are said to be owing to learning. 5. *Fallacia accidentis*, in which the sophist represents what is merely accidental as essential to the nature of the subject. 6. By deducing a universal assertion from what is true only in particular circumstances, and the reverse: thus, some men argue, "transcribers have committed many errors in copying the Scriptures, therefore they are not to be depended on." 7. By asserting any thing in a compound sense which is only true in a divided sense. So, when the Scriptures assure us that the worst of sinners may be saved, it does not mean that they shall be saved while they remain sinners, but that if they repent they may be saved. 8. By an abuse of the ambiguity of words. Hume reasons thus, in his Essay on Miracles: "Experience is our only guide in reasoning concerning matters of fact; now we know from experience, that the laws of nature are fixed and invariable. On the other hand, testimony is variable, and often false; therefore, since our evidence for the reality of miracles rests solely on testimony which is variable, and our evidence for the uniformity of the laws of nature is invariable, miracles are not to be believed." The sophistry of this reasoning depends on the ambiguity of the word *experience*, which in the first proposition signifies the maxims which we form from our own observation and reflection; in the second it is confounded with testimony; for it is by the testimony of others, as well as our own observation, that we learn whether the laws of nature are variable or invariable. The Essay on Miracles may be recommended to those who wish to see more examples of sophistry; as we believe most of the eight species of sophisms which we have mentioned are well illustrated by examples in that essay.

SOPHIST, an appellation assumed in the early periods of Grecian history, by those who devoted their time to the study of science. This appellation appearing too arrogant to Pythagoras, he declined it, and wished to be called a *philosopher;* declaring that, though he could not consider himself as a wise man, he was indeed a lover of wisdom. True wisdom and modesty are generally united. The example of Pythagoras was followed by every man of eminence, while the name *sophist* was retained only by those who with a pomp of words made a magnificent display of wisdom upon a very slight foundation of knowledge. Those men taught an artificial structure of language, and a false method of reasoning, by which, in argument, the worse might be made to appear the better reason. In Athens they were long held in high repute, and were supported, not only by contributions from their pupils, but by a regular salary from the state. They were among the bitterest enemies of the illustrious Socrates, because he embraced every opportunity of exposing to contempt and ridicule their vain pretensions to superior knowledge, and the pernicious influence of their doctrines upon the taste and morals of the Athenian youth.

SOPHOCLES, the famous tragic poet, was the son of Sophilus, an Athenian, and was born in the year 495 before Christ. Although the father was only a mechanic, the son enjoyed the advantage of a good education. Superior vigour and address in the exercises of the palæstra, and skill in music, were the great accomplishments of young men in the states of Greece. In these Sophocles excelled; nor was he less distinguished by the beauty of his person. He was also instructed in the noblest of all sciences, civil polity and religion: from the first of these he derived an unshaken love of his country, which he served in some embassies, and in high military command with Pericles; from the latter he was impressed with a pious reverence for the gods, manifested by the inviolable integrity of his life. But his studies were early devoted to the tragic muse; the spirit of Æschylus lent a fire to his genius, and excited that noble emulation which led him to contend with, and sometimes to bear away the prize from, his great master. He wrote forty-three tragedies, of which seven only have escaped the ravages of time. Having testified his love of his country by refusing to leave it, though invited by many kings, and having enjoyed the uninterrupted esteem and affection of his fellow-citizens, which neither the gallant actions and sublime genius of Æschylus, nor the tender spirit and philosophic virtue of Euripides, could secure to them, he died in the beginning of the year 405, at the very advanced age of ninety.[1] The burial-place of his ancestors was at Decelia, which the Lacedæmonians had at that time seized and fortified: but Lysander, the Spartan chief, permitted the Athenians to inter their deceased poet; and they paid him all the honours due to his love of his country, integrity of life, and high poetic excellence. Æschylus had at once seized the highest post of honour in the field of poetry, the true sublime: to that eminence his claim could not be disputed. Sophocles had a noble elevation of mind, but tempered with so fine a taste, and so chastened a judgment, that he never passed the bounds of propriety. Under his conduct the tragic muse appeared with the chaste dignity of some noble matron at a religious solemnity; harmony is in her voice, and grace in all her motions. From him the theatre received some additional embellishments; but his distinguished excellence is in the judicious disposition of the fable, and so nice a connection and dependence of the parts on each other, that they all conduce to make the event not only probable, but even necessary. This is peculiarly admirable in his King Œdipus; and in this important point he is far superior to every other dramatic writer of antiquity.

The ingratitude of the children of Sophocles is well known. They wished to become immediate masters of their father's possessions, and therefore, tired of his long life, they accused him before the Areopagus of insanity. The only defence the poet made, was to read his tragedy of Œdipus at Colonos, which he had lately finished; and he then asked his judges, whether the author of such a performance could be charged with insanity. The father upon this was acquitted, and the children returned home covered with shame and confusion.

The editions of Sophocles are very numerous, and some of them very elaborate, but we can only enumerate the more conspicuous. The *editio princeps* was published by Aldus, Venet. 1502, 8vo. This was followed by an edition published by the heirs of P. Junta, Florent. 1522, 4to; and another published by B. Junta, Florent. 1547, 4to. The text of Aldus was the basis of all the editions which preceded that of Turnebus, Paris. 1553, 4to. This is among the best of the early editions. We must not omit those of H. Stephanus, Paris. 1568, 4to, and of Canter, Antverp. 1579, 12mo. The text of Turnebus was chiefly adopted in all the succeeding editions till that of Brunck, Argent. 1786, 2 tom. 4to. This is a very elaborate as well as splendid edition, and strikingly displays the editor's acuteness and learning. The same able critic published two octavo editions, each in two volumes. We now descend to the edition of Erfurdt, Lips. 1802–11, 8 tom. 8vo. The tragedies of Sophocles have been translated into many different languages. An English version, which was favourably received, was published by Dr Francklin, Greek professor at Cambridge, Lond. 1759, 2 vols. 4to. Another was subsequently published by Mr Potter, Lond. 1788, 4to.

SOPING, a district or principality of the island of Celebes, formerly one of the most extensive in the country. In 1775 it was governed by its own king.

SOPRA, a river of Hindustan, which rises in the province of Malwah, and joins the Gilly Sinde river, after which their united streams fall into the Chumbul.

SORA, a city of Italy, in the Neapolitan province of Terra di Lavoro, the capital of a district of its own name. It stands on the banks of the river Garigliano, is the seat of a bishop, and, besides the cathedral, has five churches, and 7950 inhabitants.

SORAU, a circle of Prussia, in the government of Frankfurt, which extends over 513 square miles, with 46,400 inhabitants. The capital is the town of the same name. It stands on a large plain, is well built, and contains 430 houses, with 4060 inhabitants, who manufacture large quantities of cotton goods.

SORBONNE, or SORBON, the house or college of the faculty of theology established in the old university of Paris. It was founded in 1252, by St Louis, or rather by Robert de Sorbon his confessor and almoner, first canon of Cambray, and afterwards of the cathedral of Paris; who gave his own name to it, which he himself took from the village of Sorbon or Serbon, near Sens, where he was born. The foundation was laid in 1250; Queen Blanche, in the absence of her husband, furnishing him with a house which had formerly been the palace of Julian the apostate. The king afterwards gave him all the houses he had in the same place, in exchange for some others. The college was magnificently rebuilt by the Cardinal de Richelieu. The institution was designed for the use of poor students in divinity.

SORBONNE was also used in general for the whole faculty of theology at Paris, as the assemblies of the whole body were held in the house of the Sorbonne, and the bachelors of the other houses of the faculty came hither to hold their *sorbonnique*, or act for being admitted doctor of divinity.

SORCERY, or MAGIC, the power which some persons were formerly supposed to possess, of commanding the devil and the infernal spirits, by skill in charms and invocations, and of soothing them by fumigations. See MAGIC and APPARITIONS.

SORIA, one of the four departments into which the province of Old Castille, in Spain, is divided. Its extent is 341 square leagues, and its population amounts to 257,537 souls. It is in general a hilly district, and in some parts very mountainous. The plains are fertile, especially that of Rioja, and yield abundance of wheat and barley, and in some years it has a surplus of both these productions. Its wine is good, but not abundant; and it is deficient in a supply of oil, which is procured from the more southern provinces. This province furnishes to commerce a great proportion of the fine wool of the merinos. That of Soria is not equal in fineness to what is produced in Segovia, but is however of a good quality; and the quantity annually sent away amounts to about 2,250,000 pounds.

SORIA, a city of Spain, in New Castille, the capital of the department of that name. It is situated on the north bank of the river Duero, but too near its source to derive any benefit as to navigation. In the vicinity there are excellent pastures for sheep, with houses of various kinds to shelter them when the weather is more than usually inclement, or when they are shorn. It is not a large city, nor are the public buildings of a nature to merit a detailed description; but the extensive ruins of the ancient Numantia invite the notice of every lover of Roman antiquities. Soria contains thirteen churches, eleven monasteries, four hospitals, and 6000 inhabitants. The manufacture of silk stockings employs eighty-two looms. Some of the inhabitants are employed in soap-boiling, tanning, and in the manufacture of cloth. Lat. 41. 48. N.

SORIANG, a river of Celebes, on the west coast, which falls into the sea.

SORITES, in *Logic*, a species of reasoning, in which a great number of propositions are so linked together, that the predicate of the one becomes continually the subject of the next following, till at last a conclusion is formed by bringing together the subject of the first proposition and the predicate of the last. Such was that merry argument of Themistocles, to prove that his little son under ten years old governed the whole world: "My son governs his mother; his mother me; I the Athenians; the Athenians the Greeks; Greece commands Europe; Europe the whole world: therefore my son commands the whole world."

---

[1] Clinton's Fasti Hellenici, vol. ii. p. 23, 57, 83.

SORRENTO, a city of Italy, in the province of Naples. It is finely situated among olive, citron, and pomegranate trees, and is the seat of an archbishop. It is on the sea-coast, and has some foreign trade. The chief occupation is collecting and spinning silk. It was the birth-place of the poet Tasso. The surrounding hills are chiefly composed of tufa, which was originally lava; and the doors and window-seats are generally formed of that substance. It contains 4240 inhabitants.

SORTILEGE (*Sortilegium*), a species of divination performed by means of *sortes* or lots. The *sortes Prænestinæ*, famous in antiquity, consisted in putting a number of letters, or even whole words, into an urn; and then, after shaking them together, they were thrown on the ground; and whatever sentences could be made out of them constituted the answer of the oracle. To this method of divination succeeded that which has been called the *sortes Homericæ* and *sortes Virgilianæ*; a mode of inquiring into futurity which undoubtedly took its rise from a general custom of the oracular priests of delivering their answers in verse. It subsisted a long time among the Greeks and Romans, and being from them adopted by the Christians, it was not till after a long succession of centuries that it became exploded. Among the Romans it consisted in opening some celebrated poet at random, and among the Christians the Scriptures, and drawing, from the first passage which presented itself to the eye, a prognostic of what would befall one's self or others, or direction for conduct when under any exigency. There is good evidence that this was none of the vulgar errors; the greatest persons, philosophers of the best repute, admitted this superstition. Socrates, when in prison, hearing this line of Homer,

> Within three days I Phthia's shore shall see,

immediately said, within three days I shall be out of the world; gathering it from the double meaning of the word *Phthia*, which in Greek is both the name of a country and signifies corruption or death.

SORTINO, a city of the island of Sicily, in the province of Noto. It stands on a healthy spot on a gentle elevation, the ancient Xuthinum, 130 miles from Palermo, and is watered by a small stream. It contains 7300 inhabitants.

SORTINSKOI, a village of Tobolsk, in Asiatic Russia, seventy-two miles south-south-west of Beresof.

SOSVA, the name of two considerable rivers in Asiatic Russia, in the government of Tobolsk. The first has a course of 160 miles. It rises in the Oural Mountains, about the sixty-fifth degree of north latitude, and running almost due east, falls into the Obi near Beresof, after receiving a smaller river of the same name, called the Little Sosva. The other river rises somewhat farther to the north, in the same chain of hills, and running southwards about 200 miles, joins the Sosva, where their united streams take the name of Tauda.

SOTERIA, in *Antiquity*, sacrifices offered to the gods for delivering a person from danger; as also poetical pieces composed for the same purpose.

SOUDAN, a kingdom of Africa, situated between 11° and 16° north latitude, and 26° and 30° east longitude. See Africa.

SOUERICK, a town of Armenia, in the pachalic of Ourfa, and on the road from Ourfa to Diarbekir. It contains about 500 inhabitants, with three mosques and a strong castle. It is sixty miles north-east of Ourfa.

SOUGH, among miners, denotes a passage dug under ground to convey off waters from mines.

SOUI-TCHEOU, a city of China, of the first rank, situated at the confluence of the rivers Yan and Kincha, in a fertile though mountainous country. Long. 104. 23. E. Lat. 28. 40. N.

SOUL, the principle of perception, memory, intelligence, and volition, in man; which, since the earliest era of philosophy, has furnished questions of difficult investigation, and materials of keen and important controversy.

SOUND. So many things relating to this subject have been already treated at considerable length under the article Acoustics, that what we now propose shall be chiefly confined to the propagation of sound in the atmosphere, which, as Laplace observes, affords the most important application which has yet been made of the theory of elastic fluids. In this we shall first give the results of the principal attempts which have been made with the view of determining the velocity of sound experimentally; and shall notice more particularly some of them which are of a later date, and were made with far greater precautions than any of those mentioned under the article just cited. We shall then advert to various important oversights and imperfections which still attach to this department of science, and to certain improvements of which it seems to be susceptible.

Results of Various Experiments on the Velocity of Sound.

The reduction of such results to 32° Fahrenheit is usually made conformably to the expansion of air given by Dalton, Gay Lussac, &c., which is nearly at the rate of 1·14 foot for each degree. The expansion of Rudberg, about to be noticed, being rather smaller, would slightly lessen the reduction.

From a close examination of the twenty-eight principal experiments made in Holland in 1823, Professor Miller has, in the Philosophical Magazine for July 1839, deduced the following as the correct means of the results. The mean interval of the time in which sound travelled 17,669·28 metres is 51·9873 seconds. The mean temperature during these experiments was 11°·01 cent. The mean pressures of the atmosphere, and of the vapour in it, were ·74618 and ·00889 metres at 0° cent. respectively. Now, from Rudberg's experiments (Poggendorff's *Annalen*, xli. 558 and xliv. 119), which perhaps require to be repeated by others, it appears that on heating dry air from 0° cent. to 100°, under a constant pressure, its volume was increased from 1 to 1·365; hence, at the temperature θ cent., the pressure of the atmosphere and of the vapour in it being p and f respectively, the velocity of sound in English feet per second will be

$$1090{\cdot}77\sqrt{\left(\frac{1+{\cdot}00365\theta}{1-{\cdot}375\frac{f}{p}}\right)}.$$

This, owing to its depending on a smaller rate of expansion, exceeds 1089·5, the number in the table; but it is chiefly to be regarded as a general expression for the experimental results. The theoretical formula will be found farther on.

Chro- metc emp ed.

With the exception of Benzenberg, who had long ago used the species of clock described below with a conical pendulum, the most of the experimenters were formerly very ill provided with any adequate means of accurately measuring the intervals of time which elapse between the flash and report of the guns, as observed at the opposite station. In 1822, the French academicians employed the stop-watch of Breguet and the chronograph of Ricussec, a species of watch, one of whose hands revolves in one second, and can, without needing to stop, be made to touch with its extremity the dial-plate at any instant, so as to leave there a dot of ink, merely by suddenly pressing a small lever. In the experiments made in Holland in 1823, a clock was used with a conical pendulum which revolved 69·433 times in a minute, and was supposed capable of determining intervals to the 100th of a second, by suddenly arresting the index without stopping the clock. By means of these machines it was supposed quite practicable to determine the interval between the sight of the flash and the arrival of the report of a gun, with such precision as to obviate all material error which might arise from this cause. The importance of this, if realized, is evident from the circumstance that each tenth of a second corresponds to 110 feet of distance.

Thei sults sory.

But there is too good reason to suspect that all such ideas of attaining great accuracy in any direct measurements of the intervals of time are perfectly illusory, and that observations made with these machines can scarcely be depended on within a tenth of a second. The machines themselves may be possessed of all the perfection ascribed to them; but it would seem that the man has yet to be made who would be competent to use them. In Holland, only one centrifugal clock being employed at each station, we have no means of judging of the correctness of the observations made with it. But whoever examines the tables of results given in the *Connaissance des Tems* for 1825 (pages 364–367) will find that three and as often four machines, with as many first-rate observers, were generally employed simultaneously in determining the interval for each shot; and that instead of their results agreeing within an inconsiderable fraction, as the above ideas of great correctness would imply, they often differ by three, sometimes by four, and in one case by five tenths of a second. Something farther illustrative of this will be found under the article Clock and Watch Work (vol. vi. p. 783), where a machine has been described for determining, by indirect means, but to almost any degree of exactness, the interval in which sound passes over a small distance. The principal part is a strong clock, without compensation or other refinement, and requiring no extraordinary sort of being to observe with it.

Influence of the wind.

Although many eminent philosophers have laboured much to improve and perfect the various reductions which it is considered necessary to make on the experimental results, there is still a mistake regarding the exact influence of the wind. It seems always to be supposed that the effects of a steady wind are entirely obviated or compensated by taking the mean of the velocities of such sounds as are simultaneously produced at the two opposite stations, and also reciprocally observed at these respectively. This is in effect the view of the matter taken by Professor Moll. (Philosophical Transactions for 1824, p. 426.) Many other philosophers express the same opinion, and in particular Sir John Herschel, who recommends that all experiments on the velocity of sound be made, if possible, either in calm weather or in a direction at right angles to that of the wind. But so far is the result under this last arrangement from being entirely unaffected by the wind, that the error to which we now allude is then a maximum; and indeed in every case in which the direction of the wind is inclined to the base line, there is still a small error, which cannot be obviated by the reciprocal method.

The earlier experimenters gave themselves no concern about the influence of the wind; but its effect was in some degree eliminated by the arrangements adopted by the French academicians in 1738, though in so imperfect a manner as to leave considerable doubt regarding the accuracy of their result. In order to clear up this point, the Marquis Laplace requested the board of longitude to repeat the experiments, with the precaution of exciting sounds more nearly at the same instant from both ends of the base, in the expectation that the effects of the wind would be thereby completely obviated. The experiments were accordingly repeated in June 1822, though with no greater precision in this respect than that the times of firing the opposite shots still differed about five minutes from being simultaneous. In the experiments made in Holland in 1823, matters were so much better arranged, that the difference in the times scarcely ever amounted to a second. However, M. Arago has remarked, that when the wind is very unsteady, or comes in sudden gusts, it may still affect the mean result, especially since a sudden gust may interfere with the one sound, and yet miss the other altogether. But even when the wind is perfectly steady, the reciprocal method cannot be quite correct, unless the wind also blows directly from the one station to the other. In every other case it is more or less inaccurate, owing to the circumstance that sound is not propagated in parallel lines, but issues from its source in lines which radiate or diverge to every side; so that the same sonorous ray which, during a calm, would pass directly from the one station to the other, will not reach the latter at all when deflected by the wind into a different direction. Had our limits permitted, we should have endeavoured to show that, by applying to this the well-known principles of the composition of forces, the mean of the velocities of the reciprocal sounds will, owing to the action of the wind, come short of the true velocity, by a quantity which will in all cases be nearly expressed by $\frac{W^2}{2S}\sin^2 A$; where W is the velocity of the wind, S that of sound in still air, and A the angle which the direction of the wind makes with the base line. This correction, though generally very small, may often be several times greater than some which are usually taken into account, especially that arising from the effect of the difference of latitude and of the height of the place above the sea, on the force of gravity. For such we beg to refer to the Philosophical Transactions for 1824, 1828, and 1830. The pendulum, however, seems a more certain means of determining the differences in the force of gravity, than any merely theoretical formula, which cannot be expected to provide for particular local attractions. Besides, we suspect that during experiments on the velocity of sound, attention has not always been paid to the velocity and direction of the wind; and still more rarely have these been registered and published, so as to afford data for applying the requisite correction.

In the Reports of the British Association for 1833 and 1836, we find two able and interesting articles by Professor Challis, on the mathematical theory of fluids. Among other things, he treats at considerable length on the theory of sound, giving an analysis and notices of various essays on that subject. But these the learned professor seems, after all, never to have thoroughly examined, otherwise he could not have failed to discover that, in the mathematical investigations employed in several of the papers on which he has bestowed the largest share of commendation, there are various fundamental errors and inconsistencies, which naturally enough have led their authors into results which, independently of every other consideration, are more or less erroneous, because palpably incompatible with each other and with the premises from which they are professedly deduced. Fallacies of the sort in question have been pointed out in the Edin. Phil. Journ. (for Oct. 1826, p. 335, and July 1827, p. 153), as also in various numbers of the Quarterly Journal of Science for 1829. Some of the same errors have been likewise noticed, though not so early as in the first-mentioned journal, by an eminent Italian philosopher, Mr Avogadro, in the *Memorie dell' Academia realle della Scienze di Torino* (vol. xxxiii. p. 237), and also in a separate tract of his. Several notable instances of the like sort have been discussed and exposed in the article HYGROMETRY; but it is only one or two examples which we can notice here.

Researches of Laplace and Poisson.

With the view of accounting for the excess of the actual velocity of sound over that given by Newton's formula, it was very ingeniously suggested, in a general way, by the Marquis Laplace, about the beginning of the present century, that, in the propagation of sound, the minute rises and falls of temperature occasioned by the alternate condensations and dilatations of the air, should tend to augment the disturbance in the equilibrium of the pressure, and consequently to accelerate the transmission of sound. He did not, however, till long after, assign the form or amount of the correction for such acceleration. The first attempt toward this seems to be that of Biot in 1802 (*Journal de Physique*, tome lv. p. 173). But M. Poisson both claims and gets the no small credit of having very considerably anticipated Laplace in giving the precise form of the correction. This he is alleged to have done in a formula for the velocity of sound, communicated to the Institute as early as the year 1807, and shortly after published in the *Journal de l'Ecole Polytechnique* (cahier xiv.), and which is meant to consist of Newton's formula multiplied by a constant factor $\sqrt{1+k}$. But whilst it must be admitted that no one has written to better purpose on the theory of sound than M. Poisson has done, there seems to be a very general mistake regarding that factor. The formula is

$$\sqrt{\frac{gh}{\mathrm{D}}\left(1+\frac{aw}{(1+\alpha\theta)\gamma}\right)}=\sqrt{\frac{gh}{\mathrm{D}}(1+k)}.$$

In this he defines g to represent the force of gravity; h the height of the barometer; D the ratio of the density of the air to that of mercury; θ the temperature of the air; w the augmentation of that temperature occasioned by a condensation γ, and so small as to be considered proportional to γ; also $a = \cdot 00375$ for the co-efficient of the dilatation of the gases. But these evidently cannot make k constant, as the sequel requires it to be. After introducing the same formula and explanation of symbols in another memoir inserted in *Annales de Chimie* for May 1823, he proceeds to show that the factor $1+\frac{aw}{(1+\alpha\theta)\gamma}$, which for greater brevity he there calls simply k, is equal to the ratio of the specific heat of air under a constant pressure to its specific heat under a constant volume; which would identify $\sqrt{k}$ with the above-mentioned correction given by Laplace himself, for the first time only, in the same *Annales* for November 1816, and even then without demonstration. But it is worthy of particular notice, that the reason why the factor k in this case comes to be a correct expression for the ratio of the specific heats, is entirely owing to M. Poisson's there using γ as proportional, not to w, as above defined, but to $\frac{aw}{1+\alpha\theta}$. This will be readily seen on examining the *Annales* for May 1823 (p. 8 and 14), where, having put $\gamma = \frac{d\varrho}{\varrho}$, and $w = d\theta$, he deduces $\frac{ad\theta}{1+a\theta} = (k-1)\frac{d\varrho}{\varrho}$; and hence $k = 1 + \frac{a\varrho d\theta}{(1+a\theta)d\varrho}$ $= 1 + \frac{aw}{(1+a\theta)\gamma}$. Indeed, otherwise, $\sqrt{k}$ could neither have been constant, nor coincided with the correction of Laplace.

The leading principle in these formulæ therefore is, that as long as the total heat in the air undergoes no change (which may safely be supposed to be the fact, during a much longer interval than the theory of sound requires), it is not γ and w, but the differentials of log. $(1+a\theta)$ and of log. ϱ which are always held to be proportional; and, consequently, any changes, whether great or small, in these two logarithms themselves, must also be proportional; so that the general expression for the ratio of the specific heats, whether the simultaneous changes of ϱ to ϱ', and of θ to θ', be great or small, will be

$$1+\frac{\log.(1+a\theta')-\log.(1+a\theta)}{\log.\varrho'-\log.\varrho}=k.$$

The above inconsistency seems to have sadly misled M. Poisson's readers, particularly Professor Challis, as already cited; but it is virtually included in a more serious oversight, about to be noticed, which originated in the *Mécanique Céleste*, and has been generally more or less adopted, with implicit confidence, into almost every subsequent essay on the theories of heat and sound. In particular, it forms a leading feature in the works of Poisson, in Professor Kelland's Theory of Heat, and in Mr Lubbock's recent essay On the Heat of Vapours, which seems to have been hastily compiled, or, at any rate, from very incongruous materials.

When reviewing the first four volumes of the *Mécanique Céleste*, Professor Playfair expressed great doubts if there were then a dozen of persons in Britain qualified to peruse them. But whatever may now be the number of those who are content with merely reading the ordinary letter-press of that celebrated work, it is certain that almost none give themselves the trouble of thoroughly sifting the mathematical investigations, otherwise the serious oversights and inconsistencies which occur in some of them would be better known and appreciated, particularly the inaccuracies which pervade the greater part of the long chapter devoted to the velocity of sound. Of these, however, we shall here, for brevity's sake, take only one instance, which is selected, not so much on its own account, but because it unfortunately lies at the foundation of many of the formulæ and results with which the seventeen quarto pages following it are chiefly occupied. In the passage referred to (tome v. p. 127), there occurs an equation of the form

$$\varrho\frac{dq}{d\varrho}+kp\frac{dq}{dp}=0,$$

where p is the pressure, ϱ the density, and q the difference between the total quantity of heat which a given mass of air may then contain, and that which it contains at a temperature and pressure chosen arbitrarily. Also k is still a constant, expressing the ratio of the specific heats. We here state the matter in something like the more simple language and notation of M. Poisson, who, in the *Annales de Chimie* for August 1823, has readily deduced that equation from the two leading principles employed for it by Laplace, and which alone are essential to it, viz. the law of Mariotte, and the *constancy* in the ratio of the specific heats.[1]

From integrating the preceding equation on general principles only, and without having regard to the subject in hand, it could only be inferred that q is some indeterminate or arbitrary function of $\frac{p^{\frac{1}{k}}}{\varrho}$. But such eminent mathematicians as Laplace and Poisson, instead of being content with this general view of the matter, ought to have perceived that the conditions of the question, particularly the two principles just specified, and with which they had set out for the purpose of finding q in terms of p and ϱ, necessarily required q to be of the form $\mathrm{A} + \mathrm{B}\left(\frac{1}{k}\log.p - \log.\varrho\right)$, where A and B are constants; because this expression, independently of its being the first to present itself in the integration, is the only form or function of the above general integral which would be free from inconsistency or compatible with those two leading principles. So far, however, were they from attending to or being aware of this circumstance, that supposing themselves perfectly at liberty to adopt any particular function of $\frac{p^{\frac{1}{k}}}{\varrho}$, they made choice of $q = \mathrm{A} + \mathrm{B}\,(266{\cdot}67 + \theta)\, p^{\frac{1}{k}-1}$; where A and B are arbitrary constants, and θ is the temperature, because ϱ has been eliminated by the law of Mariotte. This form was adopted by these philosophers, that it might agree, as they supposed, with the hypothesis that the expansions of air under a constant pressure are proportional to the corresponding increments of absolute heat. But it is easily shown that such a hypothesis is quite incompatible, not only with the two leading principles, but with that very form which was on its account purposely given to q, as was first pointed out in the Edinburgh Philosophical Journal (for October 1826, p. 335), and afterwards more explicitly in article HYGROMETRY (vol. xii. p. 113), where a similar question has been consistently solved by a far more simple process of reasoning.

The precise value of the above-mentioned ratio of the specific heats is considered an important element in the theory of sound. The experiments of Desormes and Clement give 1·354; those of Gay Lussac and Welter, 1·3748; and those described under the article HYGROMETRY, 1·3333; all of which seem to be smaller than what would reconcile the theory with the actual velocity of sound. But we shall afterwards see reason for supposing that there is still another source of acceleration, which has hitherto been overlooked. In the *Annales de Chimie* for June 1829, and *Mémoires de l'Academie* (tome x. p. 147), M. Dulong treats at considerable length on the specific heat of elastic fluids; and with the view of obtaining the ratio in question for each of them, he assumes as demonstrated, that the actual velocity of sound, in any elastic fluid whatever, has to the velocity computed by Newton's formula the subduplicate ratio of the specific heat of that fluid under a constant pressure to its specific heat under a constant volume. But since it is only in air that the velocity of sound can be obtained by direct means, Dulong availed himself of a method previously employed by others, though by no means with complete success, as is evident from the discordance of their results. It consists in determining the velocity of propagation from the musical note rendered by a given cylindrical tube, and from the measured distance between two consecutive nodal sections or positions of minimum vibration. The pitch of the note gives the number of vibrations in a given time, and consequently the time of propagation over the measured interval, and therefore the velocity of the sound. By following a particular process, Dulong was enabled to give great precision to this method, which he practised first on atmospheric air, with the view of testing the soundness of the scheme; and by many successive trials he obtained a series of results, each of which, instead of exceeding, fell short of the velocity determined by direct observation. On finding therefore that this method failed in affording quite so great a ratio as he had expected or wished, Dulong abandoned it altogether, and finally adopted 1·421 as the ratio for air. This he obtained merely from taking the mean of a great number of the direct experiments which have been made on the velocity of sound in the open atmosphere, though it is usually quoted by others as the result of Dulong's own experiments with the musical notes from tubes. The same empirical mode of determining the ratio, which, however, does nothing for clearing up the theory, has been prosecuted still more closely by Dr Simons, in the Philosophical Transactions for 1830. When the number thus obtained is substituted in the formula, it certainly answers admirably; and no wonder, for it is just obtained by reasoning in a circle, which is fit to reconcile every sort of discordance.

Probable source of discordance between theory and observation.

There can be no question that great ingenuity and superior analytical skill have frequently been displayed in theoretically investigating the velocity of sound; but an important oversight, and which probably is the principal source of the remaining discrepancy between the observed and the theoretical velocities, seems to attach to all the researches of this kind with which we are acquainted, in that they are conducted upon two assumptions which are so very incompatible with each other that both cannot be true, if indeed any of them is strictly so. In the first place, it is assumed that the particles of the air, at least during a calm, vibrate accurately in the direction in which the sound is propagated. Secondly, that the air, during these vibrations, preserves or acts strictly in its fluid character. That the investigations involve the first of these assumptions, is what no one will for a moment dispute; and that they also proceed upon the second, is evident from the circumstance that the pressure of the air in such researches is always taken as strictly proportional to some particular power of the density, viz. either to the simple density, as was done by Newton, or to some higher power of it, as was in effect done by Laplace and his followers. Now, such proportionality of the fluid pressure to any uniform power of the density, would obviously require the particles constantly to observe the same uniform arrangement during their vibrations, so as to have the like distances between the adjacent particles of any small portion of the air everywhere to vary inversely as the cube root of the density, with, perhaps, the mere exception of as much difference of arrangement as is unavoidably due to the density being different in different parts of a wave of air. But it is easy to see that the two assumptions are so inconsistent that only the one of them could be strictly true; because vibrations performed accurately in the direction of the sound necessarily imply that (abstracting from the very insignificant change of distance due to the sound's being propagated in lines which are slightly diverging, because radiating from the source of sound) the distances of the particles of the air, estimated perpendicularly to the direction of the sound, would not be altered by or during these vibrations; and consequently that the density of any minute volume of the air, instead of varying alike in all its three dimensions, would vary in only one of them, namely, in the direction alone in which the sound is propagated through it.

---

[1] In the Philosophical Magazine for April 1827, it has been attempted to deduce the same equation from these two principles, incongruously coupled with a third, but with which they are utterly incompatible; and that is the needless assumption, that, under a constant pressure, the variations of absolute heat in air are proportional to those of its temperature by the common scale. But so much does the resulting equation savour of the incongruity of the data, that it has been accompanied with an admission of its being only true in one particular state of the variables, and therefore totally unfit for integration. All this might have been allowed to pass, had it not been done with the view of palming the same fatal defect upon the production of Laplace and Poisson, which however is of an essentially different character. For the equation which has been deduced from the two leading principles alone, by the accurate and consistent method of Poisson, as above cited, and also given in the Philosophical Magazine for November 1823, neither involves the needless assumption, nor has any dependence on a particular state of the variables, and so is equally true in every case. Nor was it till after having legitimately obtained that equation, that Poisson adopted any such assumption at all on this occasion, though, as we shall presently see, he unfortunately has done so in the sequel of his memoir, and thereby introduced all manner of inconsistencies.

But, independently of the incompatibility of the two assumptions, the extreme rapidity or short duration of the vibrations, whilst it gives some probability to the first, throws as much doubt on the second. Nay, any thing like a strict fulfilment of the second assumption seems, on this and various other accounts, to be extremely improbable, particularly because, in order to preserve a uniform arrangement, it would require the most of the particles, notwithstanding the rapidity of their vibrations, to describe lines deviating so much and in all manner of ways from the direction in which a clear sound is understood to be propagated, that, granting such interwoven vibrations to be possible, they could be expected to produce nothing but a very confused noise. Nor is it easy to conceive how, on that supposition, two different sounds could ever cross each other's paths without seriously interfering, which does not appear to be the fact. On the other hand, if we may not strictly adhere to the first assumption, yet, by taking a mean between the two, it would follow that the increase of the repulsion due to condensation, and the diminution of it due to dilatation, being both of them principally if not entirely confined to the direction of the sound, they would both be so much the greater in that direction; and by thus constituting an increased disturbance in the equilibrium of the repulsion reckoned in that same direction, they would have a precisely similar effect on the result, as if the pressure of the air in its otherwise supposed strictly fluid character had followed the ratio of a higher power of the density than it really does. Now, such an effect would obviously tend to shorten the duration of the vibrations, or to increase the theoretical velocity of sound, which is just the thing required in order to make it agree with observation.

The preceding remarks become far more striking with respect to the attempt which Poisson has always been considered to have made successfully (*Journal Polytechnique*, tome vii. p. 364), to show that the velocity of sound would still be the same, although the vibrations were considerable, and confined to a single straight line.

Doubts have been started if the air really consists of particles, and whether it may not rather have some undefinable constitution; but such vague considerations cannot materially alter the case, whilst there can be no question that the air, like all other matter, has inertia when at rest, and momentum when in motion; and also that as long as it is considered to preserve or act strictly in its fluid character, the matter of which any minute volume of it consists must be uniformly distributed. For it is upon properties essentially the same with these that the above remarks are founded. (E. E. E.)

Sound, in *Geography*, denotes in general any strait or inlet of the sea between two headlands. The name is given by way of eminence to the strait between Sweden and Denmark, joining the German Ocean to the Baltic, being about three miles over.

Sound-Board, the principal part of an organ, and that which makes the whole machine play. It is a reservoir, into which the wind, drawn in by the bellows, is conducted by a port-vent, and thence distributed into the pipes placed over the holes of its upper part. The wind enters them by valves, which open by pressing on the keys, after the registers are drawn, by which the air is prevented from passing into any of the other pipes besides those in which it is required.

Sound-Board also denotes a thin broad board placed over the head of a public speaker, to enlarge or extend and strengthen his voice. Sound-boards are found by experience to be of no use in theatres, as their distance from the speaker is too great to be impressed with sufficient force. But sound-boards over a pulpit have frequently a good effect, when the case is constructed of a proper thickness, and according to particular principles.

SOUNDS, Musical. See Music.

SOUNDING, the operation of trying the depth of the sea and the nature of the bottom, by means of a plummet sunk from a ship to the bottom. There are two plummets used for this purpose; one of which is called the *hand-lead*, weighing about eight or nine pounds; and the other the *deep-sea lead*, which weighs from twenty-five to thirty pounds; and both are shaped like the frustum of a cone or pyramid. The former is used in shallow waters, and the latter at a great distance from the shore, particularly on approaching the land after a sea-voyage. Accordingly the lines employed for this purpose are called the *deep-sea lead line*, and the *hand-lead-line*. The hand-lead line, which is usually twenty fathoms in length, is marked at every two or three fathoms; so that the depth of the water may be ascertained either in the day or night. At the depth of two or three fathoms there are marks of black leather; at five fathoms, there is a white rag; at seven, a red rag; at ten, black leather; at thirteen, black leather; at fifteen, a white rag; and at seventeen, a red rag.

Sounding with the hand-lead, which by seamen is called *heaving the lead*, is generally performed by a man who stands in the main chains to windward. Having the line quite ready to run out without interruption, he holds it nearly at the distance of a fathom from the plummet; and having swung the latter backwards and forwards three or four times, in order to acquire the greater velocity, he swings it round his head, and thence as far forward as is necessary; so that by the lead's sinking while the ship advances, the line may be almost perpendicular when it reaches the bottom. The person sounding then proclaims the depth of the water, in a kind of song resembling the cries of hawkers in a city. Thus, if the mark of five fathoms is close to the surface of the water, he calls, "By the mark five;" and as there is no mark at four, six, eight, &c. he estimates those numbers, and calls, "By the dip four," &c. If he judges it to be a quarter or an half more than any particular number, he calls, "And a quarter five, and a half four," &c. If he conceives the depth to be three more than a particular number, he calls it a quarter less than the next: thus, at four fathoms and three fourths he calls, "A quarter less five."

The deep-sea lead is marked with two knots at twenty fathoms, three at thirty, and four at forty, and so on to the end. It is also marked with a single knot in the middle of each interval, as at twenty-five, thirty-five, forty-five fathoms, &c. To use this lead more effectually at sea, or in deep water on the sea-coast, it is usual previously to bring to the ship, in order to retard her course: the lead is then thrown as far as possible from the ship on the line of her drift, so that, as it sinks, the ship drives more perpendicularly over it. The pilot, feeling the lead strike the bottom, readily discovers the depth of the water by the mark on the line nearest its surface. The bottom of the lead being also well rubbed over with tallow, retains the distinguishing marks of the bottom, as shells, ooze, gravel, &c. which naturally adhere to it. The depth of the water, and the nature of the ground, which is called the *soundings*, are carefully marked in the log-book, as well to determine the distance of the place from the shore, as to correct the observations of former pilots.

SOURABAYA, a large and flourishing town of Java, on the north-eastern coast, and capital of a government of the same name, subordinate to that of Java. It is situated at the mouth of a river, navigable for vessels of 100 tons one mile and a half from the sea-shore. The harbour is one of the most convenient in the island; it is broad and spacious, secure against the violence of the sea and wind; and it is mentioned by Sir Stamford Raffles, that it may be rendered impregnable to any hostile attack.[1] It is formed by the approaching extremities of the islands of Java and Madura, which in some places are not above eighty-three fathoms distance for about ten or fifteen miles. This strait is not of easy navigation, but it is marked all along by buoys; and is, besides, defended by strong batteries. One of these, a circular battery, has a commanding sweep across the Strait of Madura, which is narrowest there, being opposite to the south-west end of the island of that name. The eastern entrance being impassable for large ships, the batteries are still incomplete on that side; but the north-western entrance is defended by Fort Ludowyk, distant from Gressie about six, and from Point Panka about five miles. It presents, low on the water, a hundred pieces of the finest ordnance, mounted on traversing carriages, besides some heavy mortars. The European part of the town is separated from the Chinese part, and from the native quarter, by the river; but is connected with it by a fine drawbridge. The houses are very good, some of them elegant, particularly the newly erected country-seats of private individuals. The house of the British resident at Simpang is a fine large building, close to the river; and near it the general hospital is unequalled in elegance and commodiousness. Sourabaya has been greatly improved within these few years, in proportion as the neighbouring town of Gressie has fallen into decay. A fine arsenal, and other extensive works, calculated for equipments on a very large scale, were formed by General Daendels at this place. Vessels are built and equipped at Sourabaya. Abundance of timber is procured from the adjoining forests, which is floated down the river that takes its rise from a large inland lake encircled with high mountains. Here is also a mint, from which silver and copper coins are issued. A new government-house was begun at Sourabaya, and was designed to be a splendid edifice; but the foundation of the front range having sunk, and endangered the building, the plan was abandoned, and that part which continued firm was converted into store-rooms. Ships from Batavia bound to China or the Philippines generally touch for refreshments at this place, especially during the north-west monsoon. The surrounding country is fertile, and shaded by thickets of bamboos, bananas, and other shrubs. The adjacent country is remarkably populous; and the villages of the Javanese, Malays, and Chinese are so populous that they appear to be a continuation of the town. Long. 112. 55. E. Lat. 7. 14½. S.

SOURERA, a town of Hindustan, province of the Circars, and district of Ganjam. Long. 84. 37. E. Lat. 19. 53. N.

SOURGOUTE, a small town of Asiatic Russia, situated on the Obi, in a climate so severe that no grain can be raised in the neighbourhood. The town consists of 168 houses, and contains two churches. It is the residence of a commissary, who collects an annual tribute of furs from the Ostiaks, the inhabitants of the country.

SOURGOUTE, a river of Tobolsk, in Asiatic Russia, which falls into the Obi near the town of the same name, after a course of 100 miles.

SOUTCHEOUFOU, a large city of China, and capital of the province of Kiangnan, situated on the great canal, not far from its southern termination at Hangtcheoufou. It is one of the finest cities in China, noted for the beauty of its site, which is intersected by rivers and canals, and is compared by Europeans to Venice. This city is celebrated as an emporium of pleasure, and supplies the country with the choicest rope-dancers, jugglers, and the best actors; is famed for the beauty of its females; and is, in consequence, the residence of great numbers of the rich and voluptuous Chinese. The walls are more than four leagues in compass; and the suburbs extend along the canal, which is everywhere crowded with large barks, that afford a permanent residence to many of the inhabitants. It has an extensive manufacture of brocade and embroidery; and, from the continual bustle and crowds in the streets, it has the appearance of a great centre of trade. Long. 120. E. Lat. 31. 22. N.

SOUTH, one of the four cardinal points from which the winds blow.

SOUTH, *Robert*, an eminent divine, was the son of William South, a merchant of London, and was born at Hackney, near that city, in 1633. He was educated at Westminster school, and afterwards in Christ-Church College, Oxford. In 1654, he wrote a copy of Latin verses to congratulate Cromwell upon the peace concluded with the Dutch; and the next year a Latin poem, entitled *Musica Incantans*. In 1660, he was elected public orator of the university; and the following year became domestic chaplain to Edward earl of Clarendon, lord high chancellor of England. In 1663 he was installed prebendary of Westminster, admitted to the degree of D. D., and had a sinecure in Wales bestowed on him by his patron, the earl of Clarendon; after whose retirement into France in 1667, he became chaplain to the duke of York. In 1670 he was installed canon of Christ-Church; and in 1676 attended as chaplain to Laurence Hyde, Esq. ambassador extraordinary to the king of Poland. In 1678 he was presented to the rectory of Islip in Oxfordshire; and in 1680 rebuilt the chancel of that church, as he afterwards did the rectory-house belonging to it. After the revolution he took the oath of allegiance to King William and Queen Mary, though he excused himself from accepting a great dignity in the church, vacated by the personal refusal of that oath. His health began to decline several years before his death, which happened in 1716. He was interred in Westminster Abbey, where a monument is erected to his memory. He published, 1. Animadversions on Dr Sherlock's Vindication of the Holy and ever Blessed Trinity; 2. A Defence of his Animadversions; 3. Sermons, 8 vols. 8vo. And after his decease were published his *Opera Posthuma Latina*, and his posthumous English Works. Dr South was remarkable for his wit, which abounds in all his writings, and particularly in his sermons; but at the same time they equally abound in ill humour, spleen, and satire. He was remarkable for being a time-server. During the life of Cromwell he was a staunch Presbyterian, and then railed against the Independents; at the Restoration he exerted his pulpit-eloquence against the Presbyterians; and in the reign of Queen Anne was a warm advocate for Sacheverel.

---

[1] Raffles's History of Java, vol. i. p. 12.

South Cape, at the southern extremity of New Holland. Long. 146. 56. E. Lat. 43. 47. S.

South-east Islands, a group of islands, forming part of Recherche Archipelago, on the south coast of New Holland. Lat. 33. 53. S.

South Island, a small island in the Eastern Seas, near the south-west coast of the island of Boutton. Long. 122. 50. E. Lat. 5. 42. S. This is also the name of a small island in the Indian Sea, near the eastern coast of Madagascar. Long. 50. 20. E. Lat. 17. S. There is another small island of this name near the south coast of the island of Celebes. Long. 120. 51. E. Lat. 5. 45. S.

South of India, a division of Hindustan, which is of a triangular figure, and has the Krishna river for its base, Cape Comorin the apex, while the sides are formed by the coasts of Coromandel and Malabar. It is 600 miles in length from Cape Comorin to the Krishna, and 500 miles in breadth where broadest. The great feature of this extensive region is the central table-land, from 3000 to 5000 feet above the level of the sea, separated by a wild, abrupt, and mountainous country, from the low plains to the east and west, which form a belt of small but unequal breadth between the hills and the sea. In this division of India may be seen the Hindu manners in their primitive simplicity, especially in Tinnevelly and the adjacent districts. The Mahommedans are few in comparison with the native Hindus, over whom twenty centuries have passed without making any change in their habits. Southern India has suffered grievously from the devastations of war, and fully as much from the cruel extortion of its rulers. The territories comprehended in this division of the country are, a small portion of the Bejapoor province, the Balaghaut ceded districts; the Carnatic, Northern, Central, and Southern; Mysore, Canara, Malabar, Barramahal, Coimbetoor, Dindigul, Salem and Kistnagherry, Cochin and Travancore; a detailed description of which will be found under their respective appellations.

South Sea, or *Pacific Ocean*, is that vast body of water interposed between Asia and America. It does not, however, strictly speaking, reach quite to the continent of Asia, excepting to the northward of the peninsula of Malacca; for the water interposed between the eastern coast of Africa and the peninsula just mentioned has the name of the *Indian Ocean*. The South Sea, then, is bounded on one side by the western coast of America, through its whole extent, from the unknown regions in the north to the Straits of Magellan and Terra del Fuego, where it communicates with the southern part of the Atlantic. On the other side, it is bounded by the coast of Asia, from the northern promontory of Tschukotskoi Noss, to the peninsula of Malacca already mentioned. Thence it is bounded to the southward by the northern coasts of Borneo, Celebes, Macassar, New Guinea, New Holland, and the other islands in that quarter, which divide it from the Indian Ocean. Then, washing the eastern coast of the great island of New Holland, it communicates with that vast body of water encompassing the whole southern part of the globe, and which has the general name of the *Southern Ocean*. Thus does this vast ocean occupy almost the semicircumference of the globe, reaching nearly from one pole to the other, and about the equatorial parts extending almost 180° in longitude, or 12,500 of our miles. The northern parts of the Pacific Ocean are entirely destitute of land, not a single island having yet been discovered in it from the latitude of 40° north and upwards, excepting such as are very near the coast either of Asia or America; but in the southern part the islands are very numerous. See Polynesia.

South-west Cape, on the south coast of New Holland, in the South Pacific Ocean, north-west of South Cape. Long. 146. 7. E. Lat. 43. 32. S.

South-west Isles, a group of islands, seven in number, dependent on the Banda Islands. Kissier is the chief, which lies to the south-west of them all. They are low, and surrounded by shoals and rocks, and are inhabited by a ferocious and perfidious race, resembling those of New Guinea, who seem to have sprung from the Papuas or aborigines of that country, and the Caffres of Africa. They produce sandal-wood. The Dutch had a commercial establishment here. Population 36,266.

SOUTHAM, a small town of the hundred of Knightlow, in the county of Warwick, eighty-three miles from London. It has little or no trade. The inhabitants amounted in 1801 to 935, in 1811 to 1007, in 1821 to 1161, and in 1831 to 1256.

SOUTHAMPTON, a town of Hampshire, seventy-seven miles from London. It is finely situated at the junction of the river Test with the Itchen; these form an expanse of water, by which vessels may approach the town. It was anciently fortified, and the remains of its walls and castle still exist. It is one of the best-built towns of England. The High Street is broad and well paved. Southampton contains five parish churches, several alms-houses, a grammar school, some convenient bathing-houses, public rooms, and an elegant theatre. The borough was incorporated by Charles I., and is governed by a mayor, recorder, bailiffs, sheriff, and common-council men. It returns two members to parliament. It is in fact a county of itself, having its own magistrates, of whom the bishop of Winchester is one. This town has long been a place of great trade with Portugal, chiefly for the importation of port-wine and fruit. It has also some trade with France, with the islands of Guernsey, Jersey, Alderney, and especially with the Isle of Wight, to which place packet-boats are constantly sailing. The mildness of the air, the facility of making excursions by water as well as by land, the vicinity of the Isle of Wight and of New Forest, contribute to render the town a desirable place for either a temporary or a permanent residence, which is further recommended by the excellent supplies of fish, fruit, meat, and other necessaries. The railway which connects Southampton with the metropolis will greatly tend to promote its prosperity. The inhabitants amounted in 1801 to 7629, in 1811 to 9258, in 1821 to 13,913, and in 1831 to 19,324.

SOUTHEND, a hamlet in the parish of Prittlewell, in the hundred of Rochford and county of Essex, forty-two miles from London. It stands at the mouth of the Thames, opposite to Sheerness; and from its easy communication with the metropolis, it has of late years been resorted to by considerable numbers for sea-bathing.

SOUTHERNE, Thomas, an eminent dramatic writer, was born at Dublin in 1660, and received his education in Trinity College. He came young to London to study law; but instead of that, devoted himself to poetry and the writing of plays. His Persian Prince, or Loyal Brother, was introduced in 1682, when the Tory interest was triumphant in England; and the character of the Loyal Brother being intended to compliment James duke of York, he rewarded the author when he came to the throne with a commission in the army. On the Revolution taking place, he retired to his studies, and wrote several plays, from which he is supposed to have derived a very handsome subsistence, being the first who raised the advantage of play-writing to a second and third night. The most finished of all his plays are the Fatal Marriage, or the Innocent Adultery; and Oroonoko, or the Royal Slave, which is built on a true story related in one of Mrs Behn's novels.

Mr Southerne died in 1746, in the eighty-sixth year of his age; the latter part of which he spent in a peaceful serenity, having, by his commission as a soldier, and the profits of his dramatic works, acquired a handsome fortune, and being an exact economist, he improved what fortune he gained to the best advantage. He enjoyed the longest life of all our poets, and died the richest of them, a very few excepted. His plays are printed in three volumes 12mo. See the Biographia Dramatica, vol. i. p. 680.

SOUTH-MOULTON, a market-town, in the hundred of the same name, in the north part of the county of Devon, 179 miles from London, and twelve miles from Barnstaple. It stands on the river Moule, and contains many good houses, a large and handsome church, a commodious guild-hall, and a free grammar-school. The population amounted in 1821 to 3314, and in 1831 to 3826.

SOUTHWARK, a borough in the county of Surrey, but one of the suburbs of London, being only separated from it by the river Thames. The means of access have been greatly increased by a new bridge, and by the rebuilding of London Bridge. It contains six parishes, and, as to its police, is in a great degree under the control of the magistracy of the city. As it in fact forms a district of the capital, it is described under the head LONDON.

SOUTHWELL, a town of the hundred of Thurgarton, in the county of Nottingham, 139 miles from London. It is situated on a pleasing elevation above the plain watered by the river Trent. The parish church is collegiate, and well endowed, having sixteen prebendaries, besides choristers and singing boys. The chapter has jurisdiction over twenty-eight parishes. Its house was erected in 1377, and its library rebuilt in 1784. There are remains of an old palace belonging to the archbishops of York, with a beautiful walk on the north side of the church. There is a well-endowed and well-conducted free grammar-school, and a good market on Saturday. The inhabitants amounted in 1801 to 2305, in 1811 to 2674, in 1821 to 3051, and in 1831 to 3834.

SOUTHWOLD, a seaport town of the hundred of Blything, in the county of Suffolk, 105 miles from London. It is situated on the river Blythe. It is connected with the port of Yarmouth, but has a corporation of its own. The herring-fishery is extensively carried on in it, and of late years it has been resorted to for sea-bathing. The inhabitants amounted in 1821 to 1676, and in 1831 to 1875.

SOVEREIGN, in matters of government, is applied to the supreme magistrate or magistrates of an independent government or state; because their authority is only bounded by the laws of God and the laws of the state: such are kings, princes, &c.

SOVEREIGN POWER, or *Sovereignty*, is the power of making or sanctioning laws; for wherever that power resides, all others must conform to it, and be directed by it, whatever appearance the outward form and administration of the government may assume. For it is at any time in the option of the legislature to alter that form and administration by a new edict or rule, and to put the execution of the laws into whatever hands it pleases; and all the other powers of the state must obey the legislative power in the execution of their several functions, or else the constitution is at an end. In our constitution the law ascribes to the king the attribute of sovereignty; but that is to be understood in a qualified sense; that is, he is supreme magistrate, not sole legislator, as the legislative power is vested in the king, lords, and commons, not in any of the three estates alone.

SOZOMENUS, HERMIAS, an ecclesiastical historian of the fifth century, was born at Gaza or Bethelia, in Palestine. He was educated for the law, and became a pleader at Constantinople. He wrote an abridgment of Ecclesiastical History, in two books, from the ascension of our Saviour to the year 323. This compendium is lost; but a continuation of it in nine books, written at greater length, down to the year 439, is still extant. He seems to have copied Socrates, who wrote a history of the same period. The style of Sozomenus is perhaps more elegant; but in other respects he falls far short of that writer, displaying throughout his whole book an amazing credulity, and a superstitious attachment to monks and the monastic life. His work, with those of Eusebius and Socrates, was published by R. Stephanus in 1544, by H. Valesius at Paris in 1668, and by Reading at Cambridge in 1720. All these editions are in folio. Several others have likewise appeared.

SPA, a town of the Netherlands, in the province of Liege and arrondissement of Verviers. It is one of the oldest, and was the most frequented, of the continental watering places. Its name has become generic for similar springs. It is situated in a narrow valley watered by a rapid and clear brook. The town consists of detached houses of all sizes, appropriate to the circumstances of the several classes of visitors.

The most remarkable waters are, 1. The Pouhon, situated in the middle of the town, which is more strongly impregnated with steel than the others; 2. The Sauveniere, a mile and a half east from it; 3. Groisbeck, near to the Sauveniere; 4. Tonnelet, situated a little to the left of the road which leads to the Sauveniere; 5. Geronstere, two miles south from Spa; 6. Wartroz, near to the Tonnelet; 7. Sarts or Niveset, in the district of Sarts; 8. Chevron or Bru, in the principality of Slavelot; 9. Couve; 10. Beverse; 11. Sige; 12. Geremont. These four last are near Malmedy.

Dr Brownrigg was the first person who discovered that carbonic acid gas forms a principal ingredient in the composition of the Spa waters, and actually separated a quantity of this elastic fluid, by exposing it to different degrees of heat from 110° to 170° of Fahrenheit. From twenty ounces seven drams and fourteen grains apothecaries' weight of the Pouhon water, he obtained eight ounces two drams and fifty grains.

The Spa waters are diuretic, and sometimes purgative. They exhilarate the spirits; and are more cooling, and allay thirst more effectually, than common water. They are found beneficial in cases of weakness and relaxation, either partial or universal; in nervous disorders; in obstructions of the liver and spleen; in cases where the blood is too thin and putrescent; in cases of excessive discharges proceeding from weakness; in the gravel and stone; and in most cases where a strengthening remedy is wanted. But they are hurtful in confirmed obstructions attended with fever, where there is no free outlet to the matter, as in ulcerations of the lungs. They are also injurious to bilious and plethoric constitutions, when used before the body is cooled by proper evacuations.

Spa was more fashionable formerly than it is at present. There are in it manufactures of iron, wood, and gilt toys. The resident inhabitants are about 3300.

SPACAFORNO, a city of the island of Sicily, in the province of Noto. It stands in a healthy situation on a hill, near the seaports of La Marza, and Santa Maria. It contains 8100 inhabitants, employed in various trades. Near to it is the Troglodyte town of Ispica, where the houses are excavated in calcareous rocks on both sides of a narrow valley.

SPAGIRIC ART, a name given by old authors to that species of chemistry which works on metals, and is employed in the search of the philosopher's stone.

SPAHIS, horsemen in the Ottoman army, chiefly raised in Asia. The great strength of the grand signior's army formerly consisted in the janisaries, who were the foot, and the spahis, who were the cavalry.

SPAIN.

History.

The kingdoms of Spain and Portugal together form what is called the Pyrenean Peninsula, the most southerly, and at the same time the most westerly, portion of Europe. Except on the north-east, where it is connected with the rest of Europe by an isthmus about one hundred miles in breadth, this peninsula is wholly surrounded by the ocean. Spain, which occupies by far the greater part of it, has for its boundaries on the south and south-east the Mediterranean Sea; on the west, partly the long and narrow territory of Portugal, partly the Atlantic Ocean; on the north, the Bay of Biscay; and on the north-east the Pyrenees, a chain holding the second rank among the mountains of Europe, and forming a well-defined line of separation between France and Spain.

That the Peninsula was peopled at a very early period seems abundantly certain, but by whom it would be vain to inquire. The traditions which ascribe its colonization to Tubal, the grandson of Noah, may be allowed to repose undisturbed in the obscurity of the chronicles in which they are embodied. The earliest inhabitants whom history makes known to us were the Iberians, a race probably of Asiatic origin. At some period lost in the depths of antiquity, the Celts, amid their wide-spread migrations, penetrated into the Peninsula; but we are still ignorant how they entered the country, and whence they came, although these subjects have been matter of keen disputation. The two nations appear at first to have contended for the sovereignty of the soil, but finally to have amalgamated, to have shared the country between them, and, as a united people, to have assumed the compound name of Celtiberians. They were split into numerous tribes or clans, each of which occupied its own particular territory.

The delightful climate which Spain enjoys, the fertility of its soil, and the mines of gold, silver, and iron, by which it is enriched, proved powerful attractions to the Rhodians and Phœnicians, who established colonies in the country at a very early period. But the Carthaginians were the people who obtained the firmest footing in it. Availing themselves of the pretext of commerce, they frequented the coast of Cadiz, where they succeeded in erecting fortresses, dwelling-houses, temples, and buildings where business was transacted; and pushing their conquests into the interior as well as along the coast, they at length made themselves masters of the whole of Bætica or Andalusia, employing force when artifice failed. The Spaniards were roused to make resistance, but it was too late. Hamilcar, father of Hannibal, succeeded in overrunning a considerable part of the country, and bringing it, at least nominally, under subjection to Carthage, 238 years before the birth of Christ. He extended his conquests towards Murcia, Valencia, and Catalonia, in the latter of which provinces he founded the city of Barcelona. This conqueror having perished in a battle fought with some of the native tribes, was succeeded by his son-in-law Asdrubal, who built the port of New Carthage, now called Carthagena. The rapid strides which the Carthaginians had made towards the total subjugation of the Peninsula, aroused the fears of the Greek colonies situated on the coast of Catalonia and Valencia, and alarmed those tribes in the interior who still stoutly maintained their independence. Too weak to make head against Carthage themselves, they applied to the Romans for assistance. This great nation had long regarded with a jealous eye the growing prosperity of its rival Carthage, and eagerly embraced the cause of the discontented states. In the character of ally and protector, Rome sent a deputation to Carthage, and obtained from its senate two important concessions; that the Carthaginians should not extend their conquests beyond the Ebro; and that they should not disturb the Saguntines and the other Greek colonies. But these conditions, although agreed to, did not correspond with the gigantic designs which Asdrubal had formed. The Romans, fully aware of the vast riches which the Carthaginians drew from Spain, and of the immense value of such a country to themselves in prosecuting their own ambitious schemes of foreign conquest, had entered into close alliance with some of the discontented tribes, no doubt with the ulterior view of subjecting them to their own domination. Saguntum, one of the most flourishing cities of the Peninsula, was one of these allies of Rome; and Asdrubal, in the prosecution of his design of subduing the whole of Spain before Rome could send succours to the confederates, collected a considerable force and marched against this city. On his way, however, he was assassinated by a slave; but the chief command passed into still abler hands, those of the renowned Hannibal. This famous Carthaginian was then in his twenty-fifth year, and greatly esteemed for his valour and his talents. After having conquered the kingdom of Toledo, he besieged Saguntum with his whole force, which is said to have amounted to 150,000 men. The Romans lost much time in fruitless attempts at negociation, and failed to send prompt succour to its faithful ally. The consequence was, that after a vigorous defence, the Saguntines were so reduced by hunger and fatigue, that they retired from the walls into the centre of the city, where they amassed all their valuable effects, and every thing combustible, into one vast pile. Placing their wives and children around it, they themselves issued from the gates and plunged sword in hand into the midst of the Carthaginians. The slaughter was prodigious on both sides, but in the end the Saguntines were cut off almost to a man. No sooner was their fate known in the city than their wives set fire to the pile, and precipitated themselves and their children into the devouring element. Thus perished Saguntum, one of the largest and most flourishing cities of Spain; and its destruction may be regarded as the opening of the second Punic war. Of the contests carried on between the Carthaginians and the Romans, till the final subjugation of the former, and the consequent incorporation of its territories with the Roman empire, an account will be found under the articles CARTHAGE and ROMAN HISTORY. We shall only in this place notice such leading events as are necessary to give clearness and connection to our narrative.

Two centuries were required by Rome to effect the total subjugation of Spain, that is, from the first invasion of the country by Cneus Cornelius Scipio in the year 218 B. C., till the last tribes, the Cantabrians and Asturians, laid down their arms to Augustus in the year 19 B. C. No other conquest had cost Rome so much. The numbers who perished in the field of battle, and the amount of treasure sacrificed, are not to be calculated. At the same time, scarcely any other acquisition was productive of so much advantage to the state, from the inexhaustible riches of the country. After the destruction of the Carthaginian power in Spain, this country was regarded as a Roman province, received the name of Hispania, and was divided by the senate into Citerior and Ulterior, or Hither and Farther; the Ebro serving as a boundary between the two. Each of these was governed by a prætor, annually appointed by Rome. The extortions of these functionaries very soon became so oppressive to the natives, that they at last resolved on attempting to rid themselves of their unprincipled rulers. Viriathus, a native of Lusitania, the most remarkable man in the ancient history of Spain, collected a considerable body of malcontents, and took the field against the Romans. Not only by stratagems and sudden surprises, but in regular pitched battles, he succeeded in foiling the most valiant officers of the Roman legions. For above eleven years he bade defiance to the formidable hosts of the invader. To subdue him by force of arms was found impossible, and the base spirit of Q. Servilius Cæpio had recourse to treachery. The offer of a magnificent recompense stimulated three of the followers of Viriathus to assassinate him, which bloody deed they accomplished whilst he lay asleep. It is some consolation to record, that the murderers were disappointed of their reward, and dismissed from the Roman camp with insults and contempt. The indomitable spirit of independence which animated the Spaniards was not, however, broken by the death of their great leader. The Numantians, in particular, still remained fiercely hostile to the Romans, and the destruction of Numantia was decreed by the senate. Scipio Æmilianus, the conqueror of Carthage, was appointed to the command of the legions destined for this service, and the city was closely invested by a powerful army. While food was left to the besieged, they defied all the efforts of the Romans to take their city. Famine however humbled them into submission, and they sued for mercy, but in vain. Driven to desperation, the wretched remains of the defenders issued from the gates, and fell with fury upon the Roman intrenchments; but they were forced back within the walls. Æmilianus had formed the cruel resolution of starving them into an unconditional surrender. Rather than yield to this, the Numantians determined, in imitation of the Saguntines, to make a sacrifice of themselves, and of all that was valuable which they possessed. This resolution they carried into effect under circumstances even more shocking than those which accompanied the destruction of Saguntum. When the victor entered the city, not a human being remained alive to grace his triumph; nothing met his eyes but smouldering ruins and a horrible solitude. This event took place in the year 133 B. C.

After the destruction of Numantia, three fourths of the Peninsula submitted to Rome; and nothing very remarkable occurs in its history till the time of the civil war between Marius and Sylla. The latter having crushed the Marian faction, proscribed those who had taken a part in it, whom he could not immediately destroy. Among these was Sertorius, who had previously served in Spain as a tribune; a man of great bodily and mental endowments, of consummate valour, and experience in the art of war, but whose ambition was equal to his nobler gifts. Having escaped to Spain, he there succeeded in gaining over to his interest several of the native tribes, raised a considerable army, and routed the Roman legions in repeated engagements. He introduced a strict order of discipline among his troops, founded public schools, constituted a senate in imitation of that of Rome, and attempted to establish in Spain a rival sovereignty to that of Italy. But, in the midst of these brilliant though ambitious undertakings, Sertorius was basely assassinated by his subaltern Perpenna, in the year 73 B. C. With the death of this great captain expired the last faint glimmer of national independence. Pompey, and afterwards Julius Cæsar, reduced most of the native tribes to subjection. After the fall of Pompey in Africa, his eldest son selected Spain as the fittest scene for opposing the dreaded dictator. For the fourth time, Cæsar hastened to the Peninsula, and, on the plains of Munda, gained a bloody but decisive victory over the younger Pompey, who was slain in attempting to effect his escape from the country. Augustus, the successor of Cæsar, effectually secured the dominion of Rome over Spain, having reduced the Asturians, Galicians, and Cantabrians, the bravest and most warlike of the native tribes. Spain now began to rest from the continual wars with which it had been devastated from the period of the Carthaginian conquest, and quietly submitted to the domination of Rome, from which it received its religion, its laws, its manners, and its language.

It has already been noticed that the country was at first divided into two provinces, Citerior and Ulterior, between which flowed the Ebro as the natural boundary. With the advance of the Romans the size of the provinces increased, but it is impossible to define their exact limits before the time of Augustus. This emperor, less desirous of effecting new conquests than of securing the old, made arrangements for improving the condition of the whole peninsula. Out of the two provinces he formed three, and gave them the names of Tarraco, Lusitania, and Bætica. Under the pretext of saving time and trouble to the senate, but really for the purpose of retaining power over the whole army in his own hands, he undertook the management of two of the provinces, in which, on account of the pretended insecurity of their situation, a considerable number of troops was maintained. Only Bætica came under the direct control of the senate. A proconsul, who had his seat at Hispalis, was installed governor of this province, but without any military power; whilst in the imperial provinces, a legatus Augustalis in Emerita, and a legatus proconsularis in Tarraco, exercised complete civil and military authority. Subsequently the province conceded to the senate fell entirely under the sway of the emperor, when the governor received the name of præses or president. The districts being very extensive, it was found necessary to appoint inferior officers; under the legate of Lusitania was placed a vice-legatus militaris, and there were three placed under the consular legates of Tarraco. A legate and a quæstor were subject to the proconsul of Bætica. In this manner the country as a whole was divided. Let us now take a glance of the constitution and condition of the towns.

After the complete subjugation of the Peninsula, the cohorts, composed principally of the natives of the country, were transplanted to the most distant parts of the empire, while Roman legions were sent into Spain to supply their place. No arrangement could have been made that was better calculated to give a Roman impress to the character of the people, and to their manners, customs, and establishments. In the interior of the country, towns purely Roman sprung up, small tracts of country having been conferred on soldiers as a reward for their services. Thus the town of Leon is indebted for its name and origin to the seventh legion, which settled there; and in the same manner arose Emerita Augusta (Merida), Pax Julia (Beja), Cæsar Augusta (Saragossa), and many others. Originally, most of the cities managed their own affairs; but when Caracalla declared all his subjects throughout his vast empire Roman citizens, the constitutions of the cities of Spain were made uniform with those of the other cities of the empire. Rome, the capital, was the great type to which they all conformed. For purposes of general police, and for the superintendence of public works, fortresses, entertainments, and the like, ædiles were appointed in provincial towns, whose office, however, was one more of pomp and honour than emolument. The affairs of the cities were universally administered by a council or curia, the members of which, called *decuriones*, were chosen from among the richest and most respectable of the inhabitants. As advocates or defenders of the people, there were the *defensores civitatum*, who neither belonged to the body of the decurions nor to the army, but formed rather a sort of check upon these, and resisted the encroachments of power on the rights of the citizens. We pass over a number of other subordinate functionaries, whose duties are either imperfectly known, or, where known, of minor importance.

All matters not cognizable by the legal tribunals, nor af-

History.

fecting the interest of the emperor, were discussed in the assembly of the decurions. For all important affairs, such as those affecting the welfare of the whole district, the decurions of the principal city of a province could call a general assembly, *concilium*, to which the other towns sent plenipotentiaries. Long after the comitia had ceased to exist in Rome, the province enjoyed the privilege of calling together such meetings; and they served at the same time as a means of making known their wants to the emperor.

Of all the provinces incorporated with the Roman empire, there was not one productive of so much gain, not one in which such inexhaustible sources of wealth were discovered, as the Pyrenean Peninsula. Mines, rich in the precious metals,[1] satisfied the thirst of the Romans for gold; and a soil nowhere surpassed in productiveness filled their granaries with corn. During the republic the Peninsula was laid under the obligation of supplying the capital of the empire with the twentieth part of its corn harvests. The price paid for the grain was fixed by the Roman senate itself, a convenient way of obtaining cheap provisions.

While Spain continued to be ravaged by war, the Romans did not in general bind themselves to a regular system of taxation, but only drew as much from the Peninsula as it was convenient for it to pay at the time; but when the conquest of the country was completed, a fixed rate of taxation was introduced. Consequently, after Augustus had divided Spain in the manner which we have described, the senate sent quæstors into the provinces to collect the taxes. In those provinces placed under the immediate control of the emperor, there were procurators employed; and functionaries of this class were also appointed to look after the monies received by the officers of the senate, the application of the whole being under the entire management of the emperor. These procurators were likewise extremely useful in preventing the subordinates from defrauding the emperor. By degrees their number increased, so that ultimately there came to be procurators, not only for the collective income of a province, but for separate branches of the taxes.

In Spain, as well as throughout the whole Roman empire, the taxes consisted of a capitation and a land tax; but by degrees, more from the extravagance of the emperors than from the necessities of the state, the people came to be burdened with a multitude of other imposts. The towns had their own particular estates and incomes, independent of those of the government, and which were managed by the civic authorities themselves. These served to defray the expenses of erecting public establishments, building fortresses, and instituting games. The contribution to the state taxes paid by the towns was levied by the magistrates from the inhabitants, in exact proportion to their wealth; hence the taxes, although they continued to rise, did not press with unequal and crushing weight upon individuals and classes. Never was Spain so wealthy, so populous, and so industrious, as during the first centuries of the empire. Aqueducts, bridges, amphitheatres, and other magnificent structures, even the ruins of some of which posterity surveys with wonder, still bear testimony to the flourishing condition of the country during that period.

When Constantine the Great assumed the purple, important changes were introduced into the empire. From the province of Tarraco he separated the governments of Carthagena and Galicia, thus making five provinces in the Peninsula, viz. Tarraco, Carthagena, Galicia, Lusitania, and Bætica. Theodosius the Great erected the Balearic Isles into a province, and the African district of Tingitania was also reckoned another, so that there were seven in all. The principal cities of these provinces were as follow: of Bætica, Hispalis; of Lusitania, Emerita; of Galicia, Bracara; of Tarraco, Cæsar Augusta; of Carthagena, New Carthage; of the Balearic Isles, Palma; and of Tingitania, Tingis. The first three were placed under consuls, and the others under presidents (*præsides*). Spain was subject to the prefecture of Gaul, and over these local governors was placed a vicar (*vicarius*), whose administration was chiefly confined to civil affairs, and the count (*comes*), whose functions were of a military nature. Sometimes, however, both the civil and military departments fell to the vicar. We have yet to mention one important event connected with the Roman conquest of Spain, namely, the introduction of Christianity into the Peninsula. This took place so early that the unanimous voice of tradition has ascribed it to St James the elder; and from the same authority we also learn that St Paul preached "Christ crucified" to the idolaters of Spain. Of course little or no reliance is to be placed on such statements; but whether the apostles or their successors propagated the gospel in these regions, certain it is that Spain can adduce her martyrs as early as the second century. There is abundant evidence to prove the antiquity of the persecutions sustained by the Christians of Spain, but our limits prevent us from entering into details.

The prosperity of the Peninsula began to decline after the death of Constantine, A. D. 337. A species of tax introduced by Diocletian, which was made to fall with paralysing weight on the middle or industrious classes, proved so pernicious in its operation, that in a short time the country presented the melancholy picture of deserted towns, fields lying waste, fruit-trees uprooted from the soil, that the possessors of the ground might lessen the value of their property, and thus escape the taxes; trade and manufactures at a stand; in short, nothing but desolation, poverty, and misery, everywhere presented themselves. It only required a strong impulse from without to overwhelm the whole country in ruins. The last day of the year 406 marks the passage of the Vandals, Alans, Suevi, and other Germanic tribes, across the Rhine. From this river to the Pyrenees, terror and dismay announced their approach, death and destruction marked their progress. For a time this great barrier of nature and of nations restrained the roving bands, and the mountain-passes were at first well guarded. But the prolific fields and wealthy mines of Spain were too rich a prey not to be reached at all hazards. Finding an opportunity, when negligence had weakened the line of defence (409), they burst like a torrent through the Pyrenean chain, and poured the tide of destruction from its base to the Pillars of Hercules. Native historians of the Peninsula describe the ravages committed by these barbarians as dreadful and revolting almost beyond parallel. The very wild beasts quitted their lairs to prey upon the human species, too emaciated by famine and pestilence to drive them back. In a word, the country was turned into a desert; and, satiated with carnage and rapine, the barbarians sat down amidst its ruins and divided it by lot. Bætica fell to the Vandals, Lusitania to the Alans, and Galicia, with a great portion of Leon and Castille, to the Suevi. Tarraco alone seems still to have been retained by the Romans.

But a fourth people, more formidable than all the rest combined, came to disturb the new settlers in their possessions. These were the Goths under Ataulphus, to whom Honorius, the Roman emperor, had ceded the fertile provinces of Southern Gaul and the Peninsula. The Gothic monarch espoused Placidia, the emperor's sister, in 414, and immediately proceeded to Barcelona, where, however, he was shortly afterwards assassinated. His successor, Sigeric, a detestable monster, shared the same fate; and the election of the Goths now fell upon Wallia, a chief every way worthy of their choice. Peace being made with Rome, hostilities were vigorously commenced against the kindred barbarians (418). The result of the war was the subjugation of the Suevi, the total destruction of the Alans, and the expulsion of the Vandals from Spain (427). But the restless and powerful Suevi were scotched, not killed. During the reign of Theodoric, Wallia's successor, they became formidable alike to the Romans and the Goths, and made many important conquests in the neighbouring provinces. Theodoric might easily have subdued them had he not been summoned to encounter a far more terrible antagonist, the renowned Attila, with his half million of mounted Huns. The death of the Gothic monarch on the plains of Chalons (451), the elevation of his son Thorismund to the vacant throne, his assassination by his brothers, and the elevation of the elder of the fratricides, Theodoric, were events which closely followed each other. The reign of the last-named prince was diversified by alternate success and disaster. The Peninsula, become one great battle-field to three contending hosts, the Goths, Romans, and Suevi, was plunged in misery, and, from the Pyrenees to the sea of Africa, was overspread with innumerable swarms, which, like so many locusts, utterly destroyed the spots on which they settled. While Theodoric was preparing to conduct an army across the Pyrenees against Remismund, king of the Suevi, he was assassinated by his brother Euric, in his capital of Toulouse (466).

---

[1] Gibbon very justly observes, "Spain, by a very singular fatality, was the Peru and Mexico of the old world. The discovery of the rich western continent by the Phœnicians, and the oppression of the simple natives, who were compelled to labour in their mines for the benefit of strangers, form an exact type of the more recent history of Spanish America." Chap. vi.

The reign of Euric was unusually brilliant and successful. He rendered himself absolute lord of the country, by extinguishing the dominion of Rome in it, and completely subjecting the Suevi. Euric was the first legislator of his nation, and the founder of the Gothic kingdom of Spain; for hitherto the country had rather been overrun than subdued. This prince died at Arles, the capital of his empire, A. D. 483. He was succeeded by his son Alaric, a weak sovereign, who, after submitting pusillanimously to many indignities, was overthrown in battle, and slain by Clovis, king of the Franks (506). Amalaric, the son of Alaric, being a minor, was for a time superseded by his natural brother Gensaleic, but ultimately ascended the throne (522). He was the first Gothic king who established his court in Spain. He fixed on the city of Seville. From the death of this prince (531) till Recared I. became king of the Goths (587), a few obscure royal names occur, regarding whom it would be a mere waste of space to enter into details. The chief act of this sovereign was to reclaim his subjects from the heresy of Arianism to orthodox Catholicism. He died in 601. Of eleven monarchs who followed, occupying a period of seventy years, none is in any way remarkable. In 673, Wamba, a man distinguished alike for wisdom, valour, and virtue, was raised, by the unanimous voice of the Gothic electors, to the throne, left vacant by the death of Receswind (672). The early part of his reign was spent in quelling intestine war. During the latter part of it he successfully cultivated the arts of peace, and built a fleet for the protection of the coast; a very wise precaution, for the Saracens had already begun to swarm all over the sea of Africa. Had Wamba been succeeded by monarchs of equal prudence and activity, the scourge of Saracenic domination, the greatest perhaps that ever afflicted any people, would probably have been for ever averted from Spain. In consequence of having sunk into a death-like trance, in which state he was apparelled in the garments of the grave, Wamba was compelled to relinquish the crown (680).

One of the most celebrated names in the line of Gothic princes is that of Roderick, who ascended the throne in 709. He owed his elevation to a party which rose against his predecessor Witiza, whose two sons, with their relations, Count Julian, governor of the Gothic possessions in Africa, and Oppas, an archbishop, are supposed to have aided the Saracens in their design of conquering the Peninsula. At all events, the party which they formed against Roderick weakened the Gothic monarchy, and thus gave encouragement to the Moors to make a descent on the country, which they effected in 711. Roderick marshalled a large army, amounting, it is said, to 90,000 men, and advanced against the audacious infidel. The hosts met upon the plains of Xeres, where was fought a battle, so bravely contested on either side that it seems scarcely unworthy to have decided the fate of a kingdom. For three days, from sunrise to sunset, the embattled squadrons fought with equal ardour and obstinacy, till victory at last declared for the Mahommedans. Roderick himself is believed to have perished in the conflict, as he was never heard of more. By this decisive battle the Moors made themselves masters of nearly the whole of Spain. The wretched remains of the Goths retired into the mountainous parts of Asturias, Burgos, and Biscay, where they maintained their independence, and perpetuated their monarchy. In a few years their power began to revive under the renowned Pelagio or Pelayo, a prince of the royal blood. But before noticing the exploits of this warrior, we shall take a brief view of the political, civil, and religious condition of the people subject to the Gothic monarchy.

The local divisions of Spain, as already laid down, underwent little or no change until some time after the descent of the Mahommedans. The power possessed by the Gothic kings was considerable; but its exercise was greatly controlled by the nobles, in general a fierce, turbulent, and haughty body. The jurisdiction of the monarch was not confined to affairs purely temporal. He nominated bishops, presided, if he chose, at ecclesiastical tribunals, convoked national councils, and regulated the discipline of the church. Next to the king in civil dignity were the dukes, who appear to have been governors of provinces. After them came the counts, whose jurisdiction is supposed to have been confined to particular cities. A number of other functionaries were subordinate to these; and besides the officers of the crown, each city or town had its municipal council. Of course there were regular courts of law instituted throughout the country, where justice was administered; the forms of procedure in these tribunals being much the same as those practised in the Spanish courts at the present day, but less tedious. There was a Visigoth code of laws, partly of Gothic, partly of Roman origin. If we pass from the civil to the military state of the country, we find that the Goths were a nation of soldiers, the obligation of service being imperative on all freemen. After the Gothic power was established in Spain, the constitution of the church underwent important changes. The pope was acknowledged as supreme head, and metropolitan sees were formed, which exercised an ecclesiastical jurisdiction over the suffragan bishops. The bishops possessed an irresponsible power over the rectors, displacing or removing them at pleasure. The cathedrals and parish churches were in general well endowed; lay patronage existed, and monasteries were introduced. As in other countries, the ecclesiastical councils were of a threefold description, diocesan, provincial, and national, convoked respectively by the bishop, the metropolitan, and the king. The Goths present nothing of literature worthy of particular notice. If we pass to the domestic arts, we find still less to admire; in every thing they consulted the useful in preference to the beautiful or magnificent. It is therefore to be concluded, that however devout, temperate, honest, and sincere the Goths might have been, as many historians attest, yet Spain under their dominion made little advancement in civilization and the elegant arts.

The Moors under Tarik and Musa subdued the fairest portion of Spain, including the largest and strongest cities of the kingdom, with a rapidity which shows how completely the power of the Goths was broken. Still many of them preferred independence under severe privations amidst the wild rocks of the Asturias, to abundance and plenty on the fertile plains of Murcia. At the head of those who sought a refuge in this mountain sanctuary was Pelayo, a prince of royal Gothic blood, and who is recognised by Spanish historians as having acceded to the throne in 718; Theodomir, the legitimate monarch, having ingloriously submitted to the yoke of the infidel. Numbers of his countrymen flocked to his standard, and his force became at length so formidable as to create alarm in the Saracens. A large army was despatched to the Asturias to crush the rising insurrection; but in attempting to gain the position where Pelayo and his resolute followers were strongly posted, the Moors were repulsed with a slaughter so terrible, that for some years they showed no inclination to assail their formidable neighbours. Various successes followed, and the Asturias, now left in the undisturbed possession of Pelayo and his band, became the asylum of the liberty and the religion of the Christians in Spain. It formed the nucleus of a kingdom, which was destined slowly but surely to increase in size from century to century, until the invaders were finally expelled from the Peninsula. Little more is known of Pelayo, than that he gained repeated victories over the Moors, and died in peace in 737. He was succeeded by his son Favila, whose reign was brief and his end tragical, he having been killed by a wild boar in 739. The subsequent history of Spain is rendered so confused by the numerous kingdoms established by Christians and Moors, that some chronological guide is necessary to render it intelligible. We shall therefore present a chronological list of the various sovereigns who reigned over different parts of the country, which had been erected into distinct and independent sovereignties. The dates given mark the years in which the sovereigns acceded to the throne; the intervening periods, of course, indicate the duration of their respective reigns. We shall commence with the Mahommedan succession, as during the earlier centuries the greater part of Spain was subject to the Moors.

MAHOMMEDAN RULERS OF SPAIN.—CORDOVA.

1. *Emirs.*—Tarik ben Zeyad and Musa ben Nozeir, 711. Abdelasis ben Musa, 714. Ayub ben Habib and Alhaur ben Abderahman, 715. Alsama ben Melic, 721. Abderahman ben Abdalla, 722. Ambisa ben Sohim, 724. Hodeira ben Abdalla and Yahia ben Zulema, 726. Othman ben Abi Neza, Hodeira ben Alhaus, and Alhaitam ben Obeid, 727. Mohammed ben Abdalla, 728. Abderahman ben Abdalla (second time), 729. Abdelmelic ben Cotan, 733. Ocba ben Albegag, 736. Abdelmelic ben Cotan again, 741. Baleg ben Bakir, and Thalaba ben Sulema, 742. Husam ben Dhizar, 743. Thueba el Ameli, 744. Yussuf el Fehri, 746.

2. *Kings.*—Abderahman I. ben Moawia, 755. Hixem I. Abderahman, 787. Alhakem ben Hixem, 796. Abderahman II. ben Alhakem, 821. Mohammed I. ben Abderahman, 852. Almonahir ben Mohammed, 886. Abdalla, brother of the former, 888. Abderahman III. grandson of Abdalla, 912. Alhakem, II. son of Abderahman III. 961. Hixem II. ben Alhakem II., dethroned to make way for his cousin Mohammed, but restored in 1010; in 1012 finally removed, 976. Suleyman, 1012. Ali ben Hamud, 1015. Abderahman IV. 1017. Alcassim ben Hamud, brother of Ali, 1018. Abderahman V., and Mohammed II. cousin of Hixem II., 1023. Hixem III. brother of Abderahman IV. 1026. Gewahr ben Mohammed, 1031. Mohammed ben Gewahr, 1044. Mohammed Almoateded, 1060. Mohammed Almosstadir, 1069. *Dynasty of the Almoravides.*—Yussef ben Taxfin, 1094. Ali ben Yussef, 1107. Taxfin ben Ali, 1144. *Dynasty of the Almohades.*—Abdelmumen, 1147. Yussef Abu Yacub, son of Abdelmumen, 1163. Yacub ben Yussef, 1178. Mohammed, son of Yacub, 1199. Abu Yacub, 1213. Abulmelic, and Abdelwahid son of Yacub, 1223. Almamon and Abu Ali, 1225.

KINGDOM OF GRANADA.

Mohammed I. Aben Alhamar, founder of the kingdom, 1238. Mohammed II. ben Mohammed, 1273. Mohammed III. Abu Abdalla, 1302. Nassir Abul Giux, brother of the preceding, 1309. Ismail ben Ferag, nephew of Nassir, 1313. Mohammed IV. ben Ismail, 1325. Yussef Abul Hagiag, brother of the former, 1333. Mohammed V. ben Yussef, 1354. Ismail II. brother of Mohammed, 1359. Abu Said, brother-in-law of Ismail II. 1360. Yussef II. Abu Abdalla, son of Mohammed V. 1391. Mohammed VI. son of Yussef II. 1396. Yussef, brother of Mohammed VI. 1408. Muley Mohammed VII. son of Yussef III. 1423. Mohammed VIII. cousin of Muley Mohammed VII. 1427. Mohammed VII. restored, 1429. Yussef IV. Aben Alhamar. Mohammed VII. restored a second time, 1432. Mohammed IX. Aben Osmin (nephew of Mohammed VII.), 1445. Mohammed X. nephew of Mohammed VII. 1454. Muley Ali Abul Hassan, son of Mohammed X. 1463. Abu Abdalla, son of Abul Hassan, 1483. Abdalla el Zagal, brother of Abul Hassan, 1484. Both princes survived the fall of Granada, which took place in 1491.

KINGDOM OF THE ASTURIAS AND LEON.

Pelayo, 718. Favila, son of Pelayo, 737. Alfonso, son-in-law of Pelayo, 739. Fruela I. son of Alfonso, 757. Aurelio, nephew of Alfonso, 768. Mauregato, bastard of Alfonso, 774. Bermudo I. nephew of Alfonso, 788. Alfonso II. son of Fruela, 791. Ramiro I. son of Bermudo, 842. Ordoño I. son of Ramiro, 850. Alfonso III. son of Ordoño, 866. Garcia, son of Alfonso III. 910. Ordoño II. brother of Garcia, 914. Fruela II. son of Alfonso III. 923. Alfonso IV. son of Ordoño II. 925. Ramiro II. brother of the same Alfonso, 930. Ordoño III. son of Ramiro II. 950. Sancho I. brother of the same Ordoño, 955. Ramiro III. son of Sancho I. 967. Bermuda II. grandson of Fruela II. 982. Alfonso V. son of Bermudo II. 999. Bermudo III. son of Alfonso V. 1027. With this sovereign the male line of the house of Leon terminated. Leon and Castille now formed separate kingdoms, the contemporaneous sovereigns of which were:—

Leon.	Castille.
	1026. Sancho el Mayor, king of Navarre; first king of Castille in right of his wife.
	1035. Fernando I. son of Sancho.
1037. Fernando I. king of Castille; king of Leon in right of his wife.	
1065. Alfonso VI. son of Ferdinando I.	1065. Sancho II. son of Ferdinando I.
	1072. Alfonso I. son of Ferdinando I. (also VI. of Leon).
	1109. Urraca, daughter of Ferdinando I., and Alfonso VII. (also sovereign of Leon).
1126. Alfonso VIII. (the emperor), son of Urraca.	1126. Alfonso II. (the emperor), son of Urraca.
1157. Fernando II. son of Alfonso the emperor.	1157. Sancho III. son of Alfonso the emperor.
	1158. Alfonso III. son of Sancho III.
1188. Alfonso IX. son of Ferdinando II.	
	1214. Enrique I. son of Alfonso III.
	1217. Fernando III. son of Alfonso IX. of Leon (afterwards king of Leon).
1230. Ferdinando III. son of Alfonso IX. (also king of Castille).	

KINGDOM OF LEON AND CASTILLE UNITED.

Alfonso X. son of Fernando III. 1252. Sancho IV. son of Alfonso X. 1284. Ferdinando IV. son of Sancho IV. 1295. Alfonso XI. son of Ferdinando IV. 1312. Pedro the Cruel, son of Alfonso XI. 1350. Enrique II. bastard son of Alfonso XI. 1369. Juan I. son of the former, 1379. Enrique III. son of the former, 1390. Juan II. son of the former, 1406. Enrique IV. son of the former, 1454. Isabel, daughter of Juan II. and her husband Ferdinando V. (the II. of Aragon), 1474. Juana, daughter of Fernando and Isabel, and Philip I. of Austria, 1504.

KINGDOM OF NAVARRE.

The first independent count of Navarre was Sancho Inigo, 873. The kings reported to have reigned prior to this period are entirely fabulous. Garcia I. (Iniguez), son of Count Sancho, and the first king, 885. Sancho I. (Garces Abarca), son of Garcia I. 905. Garcia II. (el Trembloso), son of Sancho I. 924. Sancho II. (el Mayor), son or grandson of Garcia II. 970. Garcia III. son of Sancho, 1035. Sancho III. son of Garcia III. 1054. Sancho IV. (also I. of Aragon), 1076. Pedro I. son of Sancho IV. (also king of Aragon), 1094. Alfonso I. brother of Pedro (also king of Aragon), 1104. Garcia IV. 1134. Sancho V. son of Garcia IV. 1150. Sancho VI. son of Sancho V. 1194. Thibault I. nephew of Sancho VI. 1234. Thibault II. son of the former, 1253. Henri, in right of his wife, who was daughter of Thibault II. 1270. Jeanne, queen of Philip IV. king of France, 1274. Louis Hutin (king of France), son of Jeanne, 1305. Philip, brother of Louis (also king of France), 1316. Charles I. brother of Philip (also king of France), 1322. Jeanne II. daughter of Louis Hutin, married to Philip count of Evreux, 1328. Charles II. son of Jeanne, 1349. Charles III. son of the former, 1387. Blanche, daughter of Charles III. and Juan her husband, son of Ferdinando I. king of Aragon, 1425. François Phœbus de Foix, in right of his grandmother, daughter of Juan, 1479. Catherine de Foix, sister of Phœbus, and her husband, Jean d'Albret, 1483. This kingdom united with Castille in 1512.

KINGDOM OF ARAGON.

Aragonese independence is to be dated from 1035, when Sancho el Mayor, king of Navarre and Castille, divided his states among his sons. Aragon fell to the lot of Ramiro I. 1035. Sancho I. (afterwards IV. of Navarre), son of Ramiro I. 1063. Pedro I. son of Sancho I. (also king of Navarre), 1094. Alfonso I. brother of Pedro (also king of Navarre), 1104. Ramiro II. brother of Alfonso, 1134. Petronilla, daughter of Ramiro II. 1137. Alfonso II. son of Petronilla, 1163. Pedro II. son of Alfonso II. 1196. Jayme I. son of Pedro II. 1213. Pedro III. son of Jayme I. 1276. Alfonso III. son of Pedro III. 1285. Jayme II. brother of Alfonso, 1291. Alfonso IV. son of Jayme II. 1327. Pedro IV. son of Alfonso IV. 1336. Juan I. son of Pedro IV. 1387. Martin, brother of Juan I. 1395. Fernando I. brother of Enrique III. king of Castille, elected 1412. Alfonso V. son of Ferdinando I. 1416. Juan II. (also king of Navarre), brother of Alfonso V. 1458. Fernando II. (the V. of Castille), son of Juan II. 1497. This kingdom united with Castille in 1516.

COUNTS OF BARCELONA.

During the early period of Mahommedan domination in Spain, Barcelona and all Catalonia were subject to it. In the year 801, however, the Moors were expelled from Barcelona, and a count named Bera, a native of Gothic Gaul, was nominated head of the independency. The names of his successors, eleven in number, are too insignificant to require mention individually. Alfonso Raymond, the last count, acceded to power in 1131. On his death, Barcelona was united with Aragon.

To give a connected history of these various sovereignties is quite incompatible with our limits. We can only briefly describe those more important transactions affecting the whole country, in which the Christians, by wresting portions of soil from the Moors, compelled them to retire within narrower limits, and thus circumscribed their power. Alfonso and Fruela, the sovereigns who immediately succeeded Pelayo's son, inflicted several severe blows on the Moors, and overran a considerable portion of the flat country. But what proved a more effectual check upon the Saracens than the arms of the Christians, were their own domestic quarrels. So mutable had been the government, that in the space of only forty years from the period of their first landing in Spain, no less than twenty emirs had been called, or had raised themselves, to the seat of power. On the establishment of a monarchy under Abderahman, intestine revolt was quelled for a time; but a more formidable foe from without made his appearance. This was no other than the celebrated Charlemagne, who poured his legions over the Pyrenees into the valleys of Catalonia. We shall not discuss the much agitated question as to the motives which brought this emperor into Spain. He appears to have received an invitation from some discontented Moorish governors; and in acceding to their request, he probably also listened to the dictates of his own ambition. Certain it is that he entered Spain with a powerful army, and, if we can trust his historian Eginhard, subjected the country from the Pyrenees to the Iberus. But he was soon recalled from the Peninsula by the revolt of the Saxons. In his passage through the mountain defiles, the rear of his army was attacked by the Navarrese, and cut to pieces.

It seems certain, that from the period when Charlemagne poured his legions into Navarre, he considered the country as a fief of his crown, and thus gave great umbrage to the Asturian kings. But the inhabitants of the province, averse to the sway of either, longed for independence, and this they succeeded in achieving about the year 885. The rise of this kingdom was another blow to the Saracens. So signal were the successes gained over them by the Christians of Navarre, that in the year 920 not a Mahommedan remained in the whole kingdom north of the Ebro. The kings of Asturias and Leon also rapidly extended their dominions. Ordoño II. invaded the Mahommedan possessions, and gained many advantages. In 932, Ramiro II. made an irruption into the states of the enemy, and ruined Madrid. Arabian writers boast of terrible reprisals having been made on the Christians, and assert that Ramiro himself was defeated. The Saracens having invested Zamora, Ramiro approached with a formidable army. The combatants met, and a battle ensued, more obstinately contested and bloody than any that had been fought since the days of Roderick. There can be no doubt that victory shone on the banners of the Christians, but the success was less splendid than their writers assert it to be. The accounts of all the battles fought between the Moors and the Christians in Spain are to be received with caution. The Arabian writers, to exalt the prowess of their countrymen, exaggerate mere skirmishes into great battles, and temporary and partial checks into decisive victories. In equivocal cases, they seem invariably to claim the advantage; and where they were defeated, they either obscurely hint the fact, or diminish the loss which they sustained. It is to be feared, that in many instances Christian chroniclers are chargeable with similar partiality.

The reign of Abderahman III. (912) has been extolled as the most brilliant period in the history of the Spanish Arabs. Commerce flourished, and riches were accumulated to an unexampled extent. A powerful navy was formed, and maintained in full activity; the arts and sciences were cultivated with ardour, because their professors were rewarded with princely liberality; many splendid works were undertaken in the towns of Mahommedan Spain; and the king himself was the friend of industry and of merit. Still none of the territories which had been lost in previous reigns was recovered, and the Christians were gradually becoming more and more formidable to the Moors, when Mohammed, better known as Almanzor, appeared to restore the glory of the Saracen arms. He was an eminent general, an enlightened statesman, and a patron of the liberal arts. His campaigns against the Christians proved most fatal to them. The towns were ruined, the open country was ravaged, and once more the mountains of Asturias became the inaccessible asylum of the native monarchy. At length the three powers, Navarre, Castille, and Leon, entered into a confederacy to repel the common foe. The armies met at a place situated between Soria and Medina Celi, where a drawn battle was fought. This check, and the fearful loss which he had sustained, so mortified Almanzor, that he sunk under the weight of his despair, and died, some assert by voluntary abstinence from food, in the year 1001. An event of some importance to the Christian cause was the erection of Castille into a distinct kingdom, by Sancho el Mayor, king of Navarre, the most powerful prince of his age and country. Besides Sobrarve, he held the lordship of Aragon; and in 1026, in right of his wife, a princess of Castille, he became king of that country. By his conquests he considerably extended his dominions; and the marriage of his son Fernando to the heiress of Leon gave him influence in the affairs of that kingdom; so that at the period of his death, in 1035, he was virtually master of all Christian Spain except Catalonia. Before his death he divided his states among his sons, and Aragon fell to the share of Ramiro. The independence of Aragon as a separate kingdom is therefore to be dated from 1035, the year in which Ramiro I. obtained possession of the throne.

About the middle of the eleventh century Spain may be said to have been divided into two unequal parts, by a straight line drawn from east to west, from the coasts of Valencia to a little below the mouth of the Duero. The country north of this belonged to the Christians, who as yet had the smallest and least valuable portion, while all the rest belonged to the Moors. In point of wealth and real power, both by land and sea, the latter were much superior to the former; but their perpetual dissensions materially weakened them, and every day facilitated the progress of the Christians. Indeed, had either party been united, the other must soon have been quelled; but the Christians, although they did not constantly make war upon each other like the Moors, continued from time to time to be so embroiled by domestic feuds, as to be unprepared for striking a decisive blow with the combined armies of all the kingdoms; while the same evils, existing to a still greater extent amongst the Mahommedans, rendered it impossible for their monarchs to take advantage of the untoward state of the affairs of the Christians. Among the Moors almost every city was a kingdom; and as these petty sovereignties supported one another very indifferently, they, one after another, fell a prey to their enemies. The rapidity with which the kingdom of Cordova fell to pieces has few examples in history. Alfonso I. king of Aragon, also of Navarre, and for some time of Castille and Leon, is reckoned among the most valiant princes of Spain. From his warlike habits he was surnamed *El Batallador*. He conquered Tudela, Saragossa, Tarragona, Calatayud, Daroca, Mequinencia, and much of the country south of the Ebro. Since the conquest by the Arabs, he was the first who carried the Christian ensigns into Andalusia. In 1134, however, he lost a great battle, and either perished in the conflict or died of grief shortly afterwards. This was a misfortune, but the misfortunes of the Christians were in general soon repaired, although for nearly a century their conquests were less brilliant than those achieved by *El Batallador*. At the commencement of the thirteenth century, indeed, the Moors gained some decided advantages, and reduced several important towns. But the balance was restored on the celebrated plains of Tolosa, where an enormous army of Moors from Africa was nearly annihilated. Alfonso of Castille having made some destructive inroads into Andalusia, Mohammed Abu Abdalla, emperor of Barbary, prepared to punish his audacity. It is related, on credible authority, that one of the five divisions of the army which he assembled mustered 160,000 combatants. To meet this overwhelming host, the Christian kings, fortunately at this juncture brought to terms of amity with one another, united their armies at Toledo, where they were joined by numerous volunteers from Portugal and France. On the 16th of July 1212 the Christian army descended the mountainous chain which divides New Castille from Andalusia into the plains of Tolosa, where the Mahommedan army was drawn up in battle array. The conflict which ensued was obstinate and bloody, but victory at length declared for the Christians, and its immediate consequences involved the ruin of the Mahommedan empire in Spain. The thirteenth century is distinguished by other important advantages gained by the Christians. Ferdinand III. king of Leon, afterwards of Castille, by his numerous victories made himself lord of Spain, from the Bay of Biscay to the vicinity of the Guadalquivir, and from the confines of Portugal to those of Aragon and Valencia. In 1233 he triumphed over Aben Hud, king of Murcia, Granada, Cordova, Merida, and Seville; and from that year to 1248 he successively obtained possession of Toledo, Cordova, the whole of Murcia, Jaen, and Seville. The loss of the city of Cordova, which in the eyes of the Mahommedans was sacred alike from its magnificent mosque, and from its having been so long the seat of their caliphs, was a severe blow to their power. About the same time King Jayme, the greatest name in the ancient history of Aragon, and surnamed the conqueror on account of his victories, reduced the Balearic Isles, and obtained other important victories. At this period Mahommedan Spain obeyed three sovereigns, who hated each other as cordially as they were all detested by the Christians. Mohammed, who ruled in Jaen, was the least powerful, but the most successful, of these petty kings. He successively got rid of his two contemporaries, and fixed his court in Granada, resolving if possible to extend, or at the worst to preserve, his new states against the independent walis or local governors on the one hand, and the Christians on the other. Thus the celebrated kingdom of Granada was founded in the year 1238, for that of Cordova no longer existed. During two centuries and a half, this Mahommedan state withstood the hostile attacks of its Christian neighbours, and only fell when all Spain became united under one sceptre, and was consequently rendered irresistibly superior to the kingdom of the Moors.

The first king of Granada was equally valiant in war and wise in council, but he was not in a condition to contend with Ferdinand of Castille. He submitted to do homage to him as his vassal; and during the lifetime of Ferdinand a good understanding subsisted between him and Mohammed. But in succeeding reigns war again broke out between the Moors and Christians. In 1303 the strong fort of Gibraltar was reduced by Ferdinand IV. king of Castille and Leon. But the reign of this prince was mostly one of disaster. An iniquitous league was formed by two native princes, who proposed to share the kingdom between them. The kings of France, Portugal, and Granada, were not ashamed to sanction this unhallowed compact. The king of Portugal invaded Castille, the king of Granada spread his ravages into Andalusia, and the fate of Ferdinand seemed on the point of being sealed, and his kingdom partitioned among the combined robbers. But dissensions among the confederates, and the want of money, dissolved the league, and saved Spain. The greatest battle which had been fought between the Moors and Christians since the mighty African host was destroyed on the plains of Tolosa, took place in October 1340, on the banks of the small river Salado. The Christians under Alfonso of Castille were a very small band compared with the enormous host led by the king of Granada; but the former gained a brilliant victory, the loss of the Moors having been immense. The consequence was the surrender of several fortresses; and in the following year the destruction of the Mahommedan fleet was effected by the Christians.

It is now necessary to mention some circumstances in the history of Navarre, relative to the intimate connection which so long subsisted between that kingdom and France, and which had a material influence on the destinies of Spain. The male line of the house of Sancho Inigo, founder of the sovereignty, having ended in Sancho VI., who died in 1234, leaving no issue, the Navarrese elected as their future king, Thibault, a French prince, and nephew to the deceased Sancho. Of this monarch we know little beyond an expedition to Palestine, which he undertook along with several princes of France. His two sons, who successively occupied the throne of Navarre, espoused French princesses, and thus an intimate connection with France was established. The relationship between the two kingdoms became still more close when Queen Jeanne gave her hand to Philip the Fair of France. In short, Navarre became a province of France, and for four reigns has no distinct history. In 1328, however, the kingdoms were again separated, though the sovereigns of Navarre were closely related to those of France. Charles II. surnamed the Wicked, ascended the Navarrese throne in 1349, and shortly afterwards married Jeanne, daughter of King John of France. His reign is one of perfidy, intrigue, and dishonourable alliances. Events which belong more immediately to the history of France, led to the arrest of Charles by the French monarch, and his detention in prison for several years. He effected his escape, and again resumed his old practice of intriguing, particularly against the king of France. In 1366 he entered into a league with the celebrated Black Prince of England, for the restoration of Pedro, surnamed the Cruel, who had been driven from the throne of Castille on account of his many enormities. The expulsion of this detestable monster was the act of an indignant nation, which immediately elevated his bastard brother Enrique, or Henry, count of Trastamara, to the throne of Castille. The exiled king himself appealed in person to the generosity of the English hero, and the consequence was that the Black Prince led a powerful force across the Pyrenees. In his combined army of English and Normans were some of the flower of English chivalry. Henry made every disposition in his power, resolving to hazard all in a battle. The recollection of the cruelties and oppressions of Pedro's government were a strong stimulus to his followers, and might have insured success had he only been opposed by Pedro the Cruel and Charles the Wicked; but he had to contend with the victor of Cressy and Poictiers. The battle which decided the fate of the two kings was fought near Logroño, a few miles south of the Ebro, on the 3d of April 1367. Henry nobly contested the day, as also did his antagonist, who was as brave as he was cruel. The conflict was for a short time desperate, but it terminated in the complete discomfiture of Henry, an event followed by the immediate restoration of Pedro to the Castillian throne. His gallant ally had soon reason to regret his connection with a prince equally perfidious, debauched, and bloody. Edward quitted him in disgust, without receiving payment of the sum promised to the English troops. Pedro, no longer overawed by the Black Prince, who was as humane as he was valiant, immediately set about punishing those whom he either knew or suspected of having been zealous in the cause of Henry. His late disgrace had sharpened his naturally keen appetite for blood; but we pass over the revolting details of the enormities which he committed. They produced their usual effects, the complete alienation of the minds of his subjects from him, and then a conspiracy to put an end to such barbarous tyranny. Henry, who had fled to France, entered Spain with a small force, which, however, soon became augmented to an army. Tyrants have few friends in the hour of adversity, and those who have been bribed by gold or overawed by authority to become their pliant tools, are too easily seduced from their allegiance to be trusted when the day of trial comes. Mohammed V., king of Granada, was induced to take the field in behalf of Pedro; but it was less to aid his ally than to take advantage of the confusion of the times. Pedro's army gradually melted away, and he himself, compelled to flee for shelter to a fortress, and nearly deserted by his followers, was there shortly afterwards slain by the hand of Henry. Although, as we have already noticed, this prince was a bastard, yet he quietly ascended the Castillian throne, which he bequeathed to his posterity.

For nearly a century after these events took place, the history of Spain presents little or nothing that is remarkable. The continued and petty hostilities between the native princes, or between any or all of them and the Moors, merit but slight attention. Henry IV. surnamed the Impotent, ascended the throne of Castille in 1454. The misconduct of this prince, a frivolous and contemptible debauchee, produced a conspiracy amongst his turbulent nobles, to resist his weak and flagitious administration. He was formally deposed at Avila, in a very extraordinary manner; an effigy which represented him being solemnly degraded from the royal dignities, while at the same time his brother Alfonso was proclaimed king of Castille and Leon. Henry was naturally anxious to punish the rebels, but they assumed an attitude too formidable for him. Civil war produced a total relaxation of the laws, and let loose bands of robbers, who pillaged the open country, and not unfrequently attacked and plundered the towns. In the midst of these troubles the Infante Alfonso died, an event for the present highly favourable to the king. Some attempts to raise the Infanta Isabella, his sister, to the throne, proved at first abortive; but she was the person upon whom the nobles had set their eyes as the only legitimate successor to Henry. In 1469 was laid the foundation of a union which was to prove of such unbounded advantage to Spain. Juan II. of Aragon solicited the hand of Isabella of Castille for his son and heir Don Ferdinand, king of Sicily. By distributing largesses amongst the Castillian nobles, and firmly attaching the archbishop of Toledo to his interest, Juan succeeded in his object. On the 25th of October 1469, the royal pair received the nuptial benediction in the cathedral of Valladolid. The negociations had been secretly conducted, and the whole affair was brought to a conclusion without the knowledge of Henry or his queen, a princess as licentious as himself. She had borne a daughter, the Infanta Juana, whom the whole kingdom supposed, on pretty good grounds, to be the fruit of her intrigue with Don Beltran de la Cueva, count of Ledesma, one of Henry's favourites. No sooner was Henry made acquainted with this precipitate marriage, than he resolved to leave no measure untried for securing the crown to Juana. He caused her to be proclaimed heiress of his dominions, and in his last will declared her his successor. But popular opinion is too strong even for princes. The country believed her illegitimate, and on the death of Henry in 1474, Ferdinand V. and Isabella were elevated to the throne of Castille and Leon, it being stipulated that the king and queen should reign conjointly. The king of Portugal at first espoused the cause of Juana; but the alliance was productive of no event of importance, and peace was restored between Castille and Portugal in 1479. The very same year, Ferdinand, by the death of his father, Juan II., was called to the throne of Aragon. Having received the homage of his Aragonese subjects at Saragossa, of the Catalonians at Barcelona, and of the Valencians in the capital of that province, he returned into Castille.

The reign of Ferdinand and Isabella is distinguished by great events, events of the highest importance, not only to Spain, but to mankind. It was under their auspices that Columbus brought a new world to light, and it was by their arms that the power of the Mahommedans was for ever extinguished in the Peninsula. Their first object was the regulation of the government and the enforcement of the laws, which, from the license of preceding reigns, had fallen into desuetude, or were openly defied. The king and queen were noted for a rigid administration of justice; neither for money nor favour would they spare the guilty; and there was too much to punish and correct not to give their administration a character of severity, which would have had no existence had the country not fallen into a state of civil and political disorganization almost unprecedented. The local judges were overawed by the nobles, and extraordinary judges or corregidors were appointed to see that they did their duty. This not being found sufficient to eradicate an evil which had existed for centuries, the aid of the Holy Brotherhood was sought and obtained. This association, which had existed since the middle of the thirteenth century, consisted of a number of confederated cities and towns, which maintained a considerable body of troops, in order to protect travellers and pursue criminals, and took cognizance of all violent offences against the laws, appointing courts and judges in various parts of the kingdom. New powers were reposed in this association, so that it became a powerful instrument in the hands of government, and alike terrible to robber and rebel. By this means the territorial jurisdiction of the seignoral nobles was materially abridged, while the royal prerogative was greatly extended. The prompt and impartial administration of justice restored tranquillity and order; and it had been well for the fame of these sovereigns if their salutary severity had been only directed against the disturbers of the public peace. But unfortunately they were equally severe against all who ventured to differ from the established faith. Against apostates, all converts who, after baptism, reverted to Judaism or the faith of Islam, their hatred was implacable. Their intemperate zeal led them to establish, or rather to re-organize, an ecclesiastical tribunal, which became proverbial throughout the civilized world for its enormous cruelties and injustice. This was the court of inquisition.

We now approach what is not only an important event in the reign of Ferdinand and Isabella, but an era in the history of Europe, namely, the conquest of Granada, the last possession of the Mahommedans in Spain. A sovereign so zealous for the Catholic faith as Ferdinand proved himself to be, was not likely to allow such enemies of Christianity to remain long in the Peninsula, if by force of arms he could expel them; and accordingly he early turned his attention to the subject. Every thing conspired to favour his design; the Moorish kingdom was distracted and disunited by a civil war between father and son; and Ferdinand having obtained the bull of Sixtus IV. authorizing a crusade, put himself at the head of his troops, and entered Granada. He continued the war with rapid success; Isabella attended him in several expeditions; and they were both in considerable danger at the siege of Malaga, an important city, which was defended with great courage, and taken in 1487. Baza was reduced in 1489, after the loss of 20,000 men. Gaudix and Almeria were delivered up to them by the Moorish king Alzagel, who had first dethroned his brother Alboacen, and afterwards been chased from his capital by his nephew Abdali. That prince engaged in the service of Ferdinand and Isabella, who, after reducing every other place of eminence, undertook the siege of Granada. Abdali made a gallant defence; but all communication with the country being cut off, and all hopes of relief at an end, he capitulated, after a siege of eight months, on condition that he should enjoy the revenue of certain places in the fertile mountains of Alpuxarras; that the inhabitants should retain the undisturbed possession of their houses, goods, and inheritances; the use of their laws, and the free exercise of their religion. Thus ended the empire of the Arabs in Spain, after it had continued about eight hundred years.

Its overthrow was soon followed by the expulsion of the Saracens from Spain. This expulsion, however, was not entirely effected till the 17th century. Vast numbers of the Moors, indeed, oppressed by their conquerors, abandoned a country where they could not reside with comfort and with freedom. From the reign of Ferdinand of Castille, to that of Philip III. of Spain, more than 3,000,000 of these people quitted Spain, and carried with them, not only a great part of their acquired wealth, but that industry and love of labour which are the foundation of national prosperity.

The conquest of Granada was followed by the expulsion of the Jews, under circumstances of great injustice and atrocity. This unhappy people had engrossed the greater part of the wealth and commerce of Spain, yet not being allowed to take away the value of their property in the precious metals, they were compelled to barter it for the produce or manufactures of the Peninsula, and this could not be effected except at a great sacrifice. One alternative was left them, to embrace Christianity. The inquisition exhausted first its art and then its fury to accomplish this object, but with comparatively little success. Many, indeed, to save their property, always dear to an Israelite, outwardly at least embraced the faith of the cross; but by far the greater number, in profound despair, and stripped of much of their wealth, took leave of the land of their birth. About the same time that this decree was promulgated, their Catholic majesties concluded an alliance with the emperor Maximilian, and a treaty of marriage for their daughter Juana with his son Philip, archduke of Austria, and sovereign of the Netherlands. To this period also belongs the contract concluded with Columbus for the discovery of new countries; an event which more powerfully than any other attracts the notice of posterity to this splendid reign, and which materially tended to raise the Spanish monarchy above any other in Europe. To Isabella must be ascribed the glory of the enterprise, for she it was who borrowed the sum of money necessary for the armament, and bade the great navigator depart. This great queen died in 1504, leaving her daughter Juana, and after that princess her own grandson (the celebrated Charles V.), heirs to the monarchy, but appointing her husband Ferdinand regent of the kingdom till the majority of Charles. The latter years of Ferdinand's life were embittered by family dissensions, which broke out even before Isabella had breathed her last. Juana was undoubtedly queen, for the Salic law, which excludes females, never existed in Spain. This was well known, and is important, as bearing on events which happened in more recent times. Philip therefore prepared to enforce his right, while Ferdinand, fond of power, and backed by the will of his late wife, showed a determination to maintain his position in the kingdom. But just as the affairs of Spain were assuming a serious aspect, Philip died, and Ferdinand gradually resumed his authority over the whole country. Insurrection quailed before him, the laws resumed their empire, and prosperity revisited the people. The remaining events of his reign must be briefly summed up. He solicited and obtained the hand of Germaine, niece to Charles of France, in the hope of leaving a male heir to the throne; but his anticipations were not realized. In several expeditions to Africa, important conquests were made in that country, Algiers, Tunis, and other places submitting to become vassals to the king of Spain. In 1511 he went to Italy to assist the pope against the schismatics under the protection of the king of France and the emperor. But into the interminable affairs of Italy, the critical wars carried on by Ferdinand in that country in defence of his Sicilian and Neapolitan possessions, we cannot enter. This war, however, led to one memorable result, and one not very glorious to Ferdinand. Desirous of carrying hostilities into France, he demanded from Jean d'Albret, king of Navarre, permission to march his troops through that country. The Navarrese refused, but at the same time promised to remain neutral. He broke his engagement, however, and entered into an alliance, offensive and defensive, with France. Determined to accomplish his end by force, and to punish the duplicity of the Navarrese, Ferdinand invaded Navarre, and in a short time obtained possession of the whole kingdom, annexing it to that over which he formerly ruled, and successfully defending it against the invasion of the French. This was the last great event of Ferdinand's life, and, however fortunate for the country, it was by no means honourable to the king. After a lingering illness, his death took place on the 23d of January 1516. In his last will he declared his daughter Juana heiress to all his dominions in Spain and Italy, and after her his grandson Charles. Cardinal Ximenes Cisneros was at the same time appointed sole regent of Castille till the arrival of his grandson. Ferdinand is justly regarded as the founder of the Spanish monarchy; and although his character has some dark stains upon it, intolerant bigotry being not the least conspicuous, he was certainly the greatest prince of his age, and one of the ablest and best that ever swayed the sceptre of Spain. We shall now glance at the civil and political condition of Spain under the Moors and under the Christians respectively, from the period of the Mahommedan conquest till the death of Ferdinand.

Mal ame- dan ain.

Mahommedan Spain originally comprehended nearly nine tenths of the Peninsula. Murcia, which the Arabs call Tadmir, though governed by the Christian Theodomir and his successor Athanagild, was as much dependent on the Saracens as Andalusia or New Castille. The districts over which the barbarian sway never extended were the mountains of the Asturias, Biscay, Navarre, and an angle of Aragon. Thus not only by far the greatest, but infinitely the most valuable, part of the Peninsula was comprised in the Mahommedan kingdom. Under the viceroys of the caliphs, and the immediate successors of the first Abderahman, that is, during the first three centuries, it was the admiration and terror of Europe. The revenues which the kings of Cordova derived from their ample possessions were doubtless immense, and this enabled them to maintain not only a large army of native troops, but great bodies of foreign auxiliaries. These mercenary soldiers are supposed by some of the most distinguished Arabian historians to have been the principal cause of the downfall of that splendid monarchy. The spirit of nationality was not destroyed; it was fostered by transplantation from the original soil; the Egyptians in Beja and Lisbon; the Persians in Huete; the Assyrians in Granada; the Berbers and Slavones in most of the great cities, especially about the court; the inhabitants of Damascus, Emessa, and of Old Palestine, in Cordova, Seville, Niebla, Medina Sidonia, and Algeziras; became so many rival factions, all eager in the pursuit of power, and all mutually hostile. Their frequent quarrels occasioned great disasters in the state, and allowed the ambitious no less than the desperate a long-continued impunity. In this distracted state of the kingdom, rebel chiefs contrived to retain and even to extend their governments; while the Christians, ever ready to take advantage of circumstances, drove the Saracens from city to city, and from province to province, till they finally expelled them from the country. After Cordova fell from its proud eminence, the Mahommedan power declined with great rapidity. The rulers of Toledo, Badajos, Beja, Seville, Ecija, Malaga, Granada, Almeria, Lorca, Murcia, Denia, Valencia, Lerida, Saragossa, and Huesca, all openly aspired to independent sovereignty. Many of these petty states were annihilated by the king of Seville; but his own, with those which still remained, were swept from the Peninsula by Yussef, the first emperor of the Almoravides. This African dynasty was again subverted by the still more ferocious Almohades. In the decline of the latter, the local governors again endeavoured to establish independent kingdoms. The Moorish domination thus became circumscribed within the mountainous region bounded by the sea, and by a line drawn from Malaga through Archidona, Loxa, Guardia, the Sierra de Cazorla, to the environs of Lorca. This small state was still farther limited by the succeeding sovereigns of Castile, from Alfonso el Sabio downwards, till, as we have seen, it was finally subjugated by Ferdinand the Catholic.

In all the states of Spain, whether Mahommedan or Christian, the government was absolute, but not despotic. If the Christian, as a protection against arbitrary power, could appeal to the legal code of the country which he inhabited, the Mahommedan could also invoke the provisions of the Koran, for the laws of the followers of the prophet are founded in their religion. Several of the Mahommedan potentates were the munificent patrons of literature and literary men, the names of some of whom are mentioned with respect at the present day. At the close of the eleventh century, Mahommedan Spain could boast of seventy public libraries, and of colleges, or seminaries of learning, in all the principal cities. Thus learning was much encouraged; and among these numerous collections of books were many hundred volumes by native writers. So great, in fact, was the literary reputation of the Spanish Arabs, that when the caliph of Egypt desired his library to be arranged and indexes to be made, he confided the task to two individuals of that nation. These men of learning comprised historians, poets, grammarians, orators, rhetoricians, mathematicians, astronomers, philosophers natural and moral, physicians, lawyers, and divines. It was in the physical and experimental sciences that the people most excelled, and that too at a time when many of the sciences were wholly neglected or totally unknown in the rest of Europe. Their knowledge of botany was far famed; that of chemistry was still more so. Indeed they are to be regarded, if not the founders, at least the regenerators, of that science in Europe. Their skill in medicine was great; in the mathematics they particularly distinguished themselves; the improvements which they made in algebra are well known. Optics and astronomy were much cultivated by them; nor were the useful arts less attended to, more especially agriculture, including horticulture and planting. The mechanical arts and manufactures were also carried to considerable perfection by the Spanish Arabs. Commerce was deemed no less worthy of encouragement than domestic industry. The fine arts however were less cultivated; but still all the great cities of Mahommedan Spain, Cordova, Granada, Toledo, Valencia, Ubeda, Coimbra, were deeply indebted to the Moorish inhabitants; a fact sufficiently proved by the remains of their past magnificence, which still exist.

From the foundation of the Christian states, the extent of territory comprised by each was usually variable, dependent alike on their conquests over the common enemy and among themselves. The relative extent of each at different periods may be briefly noticed. 1. When Pelayo established his little court at Cangus, the *Asturian* kingdom could only have occupied the mountainous district immediately surrounding that humble capital. By Alfonso I. this territory was extended into Galicia on the west, probably to Aragon on the east, and to the confines of Toledo on the south. Alfonso III. still further amplified the Asturian kingdom, by extending its frontiers to the Sierra de Cuenza, in the territory of Toledo, to the Duero, in Estremadura and Portugal; in one instance even as far as the Guadiana. The capital regularly continued to shift towards the centre of Spain as new territory was acquired. Thus the Asturian kingdom went on increasing till, on the incorporation of Castille with it, and the subsequent conquest of Andalusia by San Fernando, the capital of the monarchy was fixed at Seville. From the reign of San Fernando may be dated the true era of Spanish greatness. Murcia was conquered by his son Alfonso; and by his successors the Moorish kingdom of Granada was first circumscribed and finally subjugated. 2. *Navarre* (that is, Spanish Navarre), from its origin to its conquest by Ferdinand V. underwent little change in its dimensions; and its capital was always Pamplona. See the article NAVARRE. 3. The *Lordship of Barcelona*, which for some time continued dependent on the Carlovingian princes, comprehended anciently, not only Catalonia, but likewise Languedoc. The Spanish frontier, however, was subsequently held as a separate government, to which other lordships were subordinate. The dependence on France was of short duration, and appears nearly to have ceased towards the close of the ninth century, when Wifredo II., count of Barcelona, entirely cleared Catalonia from the infidels. That ruler decrees in the sovereign style, and is recognised even by the French as the founder of an hereditary state; which continued as independent a sovereignty as any in the Peninsula, till its union with Aragon, about the middle of the twelfth century. 4. *Aragon* was at first but a small mountainous region at the foot of the Pyrenees, the capital of which was Jaen, or San Juan de la Peña. The conquest of Sobrarve, Ribagorza, and Pallas, by Ramiro I.; of the Mahommedan fortresses from the Pyrenees to the Ebro by Sancho I.; of Huesca by Pedro; of Tudela, Saragossa, Calatayud, Daroca, Mequinencia, &c. by Alfonso I., amplified this little lordship into a considerable kingdom, the capital of which in 1119 was transferred to Saragossa. When Lerida and Fraga were reduced by the prince of Aragon, the Balearic Isles and Valencia by Don Jayme el Conquistador, Aragon became, next to Castille, the most extensive and powerful of the peninsular kingdoms.

The government of all the Christian states was absolute, and in the whole of them latterly it was hereditary. The powers of the sovereign varied at different times; latterly they became very great. He could concede or revoke, interpret or abrogate laws, declare war or make peace, appoint judges, levy and exact contributions, and the like. But still all was to be done *according to the ancient form*, that is, according to established custom. Other restraints were placed upon his power, and it is pretty certain that the Spanish kings were not commonly tyrannical. The true tyrants were the feudal lords, who were at perfect liberty to exercise almost royal authority within their respective jurisdictions. Of their violence and rapacity there are innumerable complaints in the national chronicles, and in the acts of the Cortes. It is worthy of remark, that the queens presided with their husbands in the Cortes, the councils, and the tribunals of justice, and that as judges, not merely as spectators. The only great feudatories of the crown, exercising a local jurisdiction, were the condes, who held different ranks and enjoyed different degrees of power. But, from the thirteenth century, the governors of provinces were termed *adelantados* (now captains-general), while those of cities, towns, and fortresses, were known as *alcaldes*. As conquest gave the Christians additional territory, admirals and constables were appointed, with power over the affairs of sea and land respectively. Of the dignities, whatever their names might be, most were doubtless of a mixed nature, partly civil and partly military. But there were functionaries who exercised an exclusively military authority. Among the officers of administration, those of the law must have occupied a prominent place. The judgment in civil or criminal cases properly depended on the counts or viscounts, who sometimes decided themselves, sometimes in concert with men learned in the law, called counsellors, and at other times they left the duty to the ordinary judges. These counsellors or judges were expressly educated for the office, and otherwise well adapted for such a situation. The forms of proceeding, which were simple and brief, were conducted in public, and the sentence was also openly delivered. From the decision of all the ordinary judges, lay an appeal to the royal tribunal, which also took cognizance of certain offences and cases. Spain can boast of an ample body of laws promulgated during the middle ages.

As the circumstances of the country altered, and the state of society advanced, it became necessary to extend or limit the existing laws, and to enact new ones. To encourage the cultivation of waste lands, the Christian kings promised to the lower orders, that if they reclaimed unoccupied wastes, formed themselves into small communities, building villages and towns, and defended their possessions against the common enemy, they should enjoy certain social privileges in addition to the profits of their industry. Of these privileges the most highly prized were those which rescued the people from the jurisdiction of their feudal tyrants, which empowered them to elect their own magistrates, to form municipal juntas, and to dispose of certain revenues arising from forests and other possessions. It may well be believed that so brilliant a reward attracted many settlers, who were thus at once raised from the rank of serfs to that of citizens. Such was the origin of many *fueros*, or provincial laws, which varied in their spirit according to the liberality of the monarch and the relative importance of the colonies. These fueros were devised with jealous care to preserve the inhabitants from feudal domination. No baron or noble could settle in a community, unless he abandoned his birthright, enrolled himself among the citizens, and owned obedience to the local fuero. So many temptations did these new communities present, in the shape of municipal posts, that many nobles were known to renounce their rank, and class themselves among the plebeians, for the purpose of obtaining them. The defects of such a system were not long in being felt, and a remedy was provided by the introduction of the "Siete Partidas," so called from the seven parts into which it is divided. It is by far the most comprehensive code of Spain, being taken from the code of Justinian, the Visigothic, the Fuero Viejo, the local fueros, as well as from the canon law.

Cortes.

Passing over the much-disputed question regarding the origin of popular representation in Spain, we find that there were present, at the Cortes held at Leon in the year 1188, "the deputies of towns, chosen by lot," that is, representatives of the people, the third estate. On these municipal towns many important privileges were conferred by successive sovereigns, the direct tendency of which was to abridge the powers of the feudal lords. But even at the brightest period of popular representation, which was the fourteenth century, the representation was never definite. Many of the great towns neglected to send any deputies at all, and those which did return them appear to have observed little proportion in the numbers. Two was the number which ought to have been returned by each, but some towns sent eight, while others of larger size sent only one or two. Indeed it seems highly probable that the privilege of sending deputies was a favour granted by the sovereign to such towns as it was his pleasure to honour. It is preposterous, therefore, to look upon the third estate as consisting of independent representatives of the nation: the members were little better than nominees of royalty, and their numbers could be increased or diminished just as it suited the purposes of government. Much as the popular representation of Castille is extolled by national writers, it seems to have been better adapted for securing and extending the power of the crown, than for protecting the rights of the people. Under Ferdinand and Isabella the last lingering traces of popular liberty were destroyed; but the power of the other orders of the state suffered at the same time a corresponding diminution, as we have already noticed. Such is a brief outline of the government and laws of Castille and Leon, the most important of the peninsular kingdoms, and almost the only ones in which the reader will take much interest, or, indeed, regarding which authentic documents remain. It may be mentioned, however, with regard to the kingdom of Aragon, that, with the exception of the lowest order, the serfs of the soil, the Aragonese possessed a greater share of individual liberty than any other people in the Peninsula. The citizens and nobles frequently coalesced for the purpose of obtaining fueros or privileges from the crown, and when thus united they were generally too powerful to be resisted. Hence numerous concessions were made by successive sovereigns, and an amount of popular freedom obtained by the people which frequently threatened the existence of the monarchy itself. Catalonia and Valencia were always distinct from Aragon, both in government and laws. Each had its Cortes, consisting of three estates, prelates, nobles, and deputies, all no less tenacious of their privileges than those of Aragon.

Lite ure, scien and gion.

Several historians of note, whose works have come down to us, flourished in the various Christian kingdoms of Spain during the period of Mahommedan domination. Poetry sprung up about the middle of the twelfth century, and some very interesting specimens of these ancient compositions still remain, particularly the *Poema del Cid*. The old Spanish ballads are well known, and celebrated throughout Europe. The scientific state of Spain, as compared with the Mahommedan, exhibits a lamentable contrast; nor does it appear that in any of the useful arts of life the Spanish Christians were equal to the Moors. The most distinguished place in Spanish science during this period has been assigned to Alfonso X. surnamed el Sabio; but even he was greatly indebted to the Arabians for the perfection which he attained. The theologians of Spain, during the middle ages, were more numerous than all her other writers put together, and the writings of many of these shining lights of the church are to be met with in the libraries of Spain. With regard to religion it is only necessary to state, that the Catholic faith prevailed in full force, and was characterized by the darkest bigotry and the fiercest intolerance, as the doings of the inquisition amply testify.

Char I.

Charles I. (V. of Germany) became king of Spain on the death of Ferdinand, but a regency had been nominated to govern the kingdom until he should attain his twentieth year. If the events and transactions in which this monarch was concerned were to be woven into the history of Spain, it would in fact be the history of almost all Europe during the period of his reign. But our business is with events purely peninsular; or if others of a more general character are occasionally noticed, it will be because they are too closely connected with the former to be separated without violence. His foreign wars, negociations, and other transactions, arose from his position as emperor of Germany, not from his being king of Spain; and an account of them will be found under the heads France, Italy, and England, to which articles the reader is referred.

The Cardinal Ximenes Cisneros, to whom the regency had been left by the deceased king, was bitterly opposed in his administration, principally by the nobles of Castille, who, envious of his dignity, displeased with his firmness and vigour, and hoping for impunity under a young monarch, soon showed a disposition to refuse him obedience. Popular discontent reached a great height; and as his best measures were misrepresented to the king, Charles perceived the necessity of making his appearance in Spain, where he arrived in 1517. Nobles and prelates hastened to meet their sovereign, and among the rest the calumniated Ximenes. But that sovereign he was not destined to see; he suddenly sickened and died, not without suspicions of poison. Charles brought with him a multitude of Flemings from the Netherlands, who soon monopolized the principal situations in church and state, and in all their dealings evinced an unquenchable thirst for gold. The favour extended to these foreigners so incensed the people, that Charles found extreme difficulty in obtaining the homage of the Spaniards. Although they swore allegiance to him, it was on certain stipulated conditions, sufficiently advantageous to themselves. In 1519 occurred an event destined to exercise great influence over his future life, over his hereditary states, in fact over all Europe. This was his election to the imperial throne of Germany, left vacant by the death of his paternal grandfather Maximilian. The Spaniards were pleased that this dignity was conferred on their sovereign; but as the old grievances continued to gall them, they were not so dazzled as to be insensible to their own interests. The leading men of many of the principal cities publicly remonstrated with Charles, and it was only by granting certain concessions that he could keep them from open rebellion. His presence having become absolutely necessary in Germany, he quitted Spain, but proceeded first to England to concert with Henry VIII. the means of humbling the power of the French king, Francis I. This monarch had been a candidate for the imperial diadem; but, disappointed in his ambition, and in hatred of his successful rival, he leagued himself even with the enemy of the Christian faith. He also laid claim to Italy, the Netherlands, and Navarre; so that war was unavoidable, and hostilities immediately commenced; for an account of which see the articles already referred to.

The turbulence of the times was not likely to be assuaged by the absence of the king from his all but revolted territories in the Peninsula. Opposition had now degenerated into rebellion; and what before might have been dignified with the name of patriotism, could only be characterized as crafty schemes of personal ambition. Unfortunately for the interests of order, the regency of Castille, where disaffection had assumed the most serious aspect, was held by a man, estimable and virtuous, indeed, but little fitted for such stormy times. The appointment of this individual, Cardinal Adrian, who subsequently wore the triple crown, had at the first given great offence to the nobles and deputies at court; but the king, though solicited, would not change him for another. The persons upon whom the fury of the mob fell were chiefly the governors and deputies of the cities and provinces. Many were massacred; open insurrection spread from city to city; and no species of crime was left uncommitted. In this critical position of the royal cause, it was fortunate that Aragon, Catalonia, and most of Andalusia, stood aloof from the confederation. Had they joined it, the evils might have been long protracted, and the whole Peninsula plunged in misery and ruin. But the revolted cities followed one another in making their submission to government; and those which did not voluntarily submit were reduced by the royal troops, now augmented to a considerable body. An attempt of the French king to seize Navarre was happily frustrated, so that in 1522 the whole country was restored to tranquillity.

In July of that year, the emperor, whose presence had been often requested by the royalists, arrived in Spain. It was expected that summary justice would be inflicted on those who had taken a prominent part in the recent disturbances; but on this occasion Charles showed a degree of clemency almost unexampled in history, very few being condemned to suffer. During the remainder of this prince's reign, the domestic tranquillity of Spain was undisturbed, except by an insurrection of the Moors, which was soon suppressed. Of two expeditions of the emperor to the African coast, to humble, if not to extirpate, the Mahommedan pirates, one was successful, the other disastrous. He compelled the Grand Turk, who penetrated into the centre of Europe, to retreat; and took his great rival, Francis I. of France, prisoner at Pavia. Such were some of his achievements in his foreign wars, by which the fame of the Spanish arms was extended throughout Europe. The mines of the west also had begun to pour their inexhaustible wealth into the country, so that the military and political power of Spain now attained its zenith, and became a source of uneasiness to other nations. In 1525 Charles married the Princess Isabella, sister of Joam III. king of Portugal. The issue of this union was, besides two daughters, the infant Philip, destined to be no less famous than his father. Charles made an ineffectual effort to procure for him the imperial crown of Germany; but in 1554 succeeded in obtaining the hand of the princess Mary of England. That the nuptial ceremony might be performed with greater splendour, he invested his son with the regal title, by abdicating in his favour his Italian possessions, the kingdoms of Naples and Sicily, and the duchy of Milan. This was but a prelude to a still more extraordinary sacrifice. It appears that from the very prime of life the emperor had meditated a retreat from the world; and that on the death of his mother Juana, in 1555, he was determined on fulfilling his long-cherished project. Many reasons have been assigned for this memorable act, but the principal cause is to be traced to his superstitious temperament; something is also to be allowed for the bad success of his arms during the latter years of his reign. Having concluded a truce with Henry, the successor of Francis, and recalled Philip from England, he assembled at Brussels the states of the Netherlands. There, amidst the most imposing solemnity ever witnessed since the days of the Roman Cæsars, he resigned the sovereignty of the Low Countries into the hands of his son. With the same august ceremony he resigned the crown of Spain, and the dominions thereto belonging; and from the monastic retreat to which he retired, he sent his resignation of the imperial diadem. The place which he had chosen for his residence was the monastery of St Justus, one of the most secluded and delightful situations in Estremadura. Here, employed in religious observances, passed the latter years of the life of the most powerful sovereign Europe had seen since the days of Charlemagne and the empire of the west. His character has been variously described by natives and foreigners; the former can see little in it to condemn, the latter nothing to admire. His policy was always close, sometimes crooked, and in not a few instances dishonourable. He was no friend either to civil or religious liberty, and may safely be pronounced a bigot. Under him the condition of Spain was more splendid, perhaps also more prosperous, than in any prior or subsequent reign. Notwithstanding his many wars, the people do not appear to have been overburdened in supporting them, for the New World poured its treasures at his feet. A new impulse was given to national industry by the markets opened for Spanish productions in the transatlantic colonies. But the brightest landscape has its masses of shade. The nobles held a power over the people which was often exercised with violence. Favouritism to foreigners was practised to an unprincipled extent, and the sale of offices became a branch of traffic. Another baneful evil was the multiplication of religious orders. Lastly, the exemption from taxation of the nobles and clergy, which threw the whole weight of public contribution on the third estate, increased the disaffection of that body, and was one of the chief causes of the subsequent decline of the kingdom. For an account of the private life and character of Charles, see the article CHARLES V.

The reign of Philip II. commenced in 1556, and extended to the year 1598. Much of it was occupied in foreign wars, to which we can only briefly advert. For an account of Philip's long, bloody, and inglorious struggle with his revolted subjects of the Low Countries, see the article HOLLAND. The circumstances which led to the invasion of Portugal, and the annexation of that kingdom to the Spanish crown, will be found fully detailed under the head Portugal. An attempt was made by the pope, in conjunction with France, to wrest from Philip his Italian dominions, but without success. The duke of Alva, the viceroy of Naples, put his troops in motion, seized several fortresses of the papal states, and the holy city began to tremble for its security. Philip himself invaded France, and inflicted a severe blow on Henry under the walls of St Quentin. The French army, under the duke of Guise, was recalled from Italy; and the pope, left at the mercy of the duke of Alva, was compelled to purchase his safety by withdrawing from the French alliance. In 1559 peace was made with France; and Philip having become a widower, further ratified the treaty by marrying Elizabeth, sister of the French king. But the Turks continued to harass Naples, although they durst not make a stand before the Spanish forces. In 1565, Philip assisted the Maltese with 10,000 Spaniards in the famous siege which they underwent from sultan Solyman. Five years afterwards, the war between the Venetian republic and the Porte again brought the Spaniards into collision with the latter power, and they had no small share in achieving the glorious victory of Lepanto. The Mahommedans, however, still continued to make descents on the Italian coast, and to harass the African possessions of Philip; but, on the whole, the war with the misbelievers was honourable to the Spanish arms.

We now approach an event of peculiar and lasting interest to every Briton, the projected invasion of England by the famous Spanish Armada. Elizabeth had certainly done much to provoke the resentment of Philip. She had succoured the insurgents of the Netherlands, fomented the disturbances in Portugal, assisted France, and her naval captains had ravaged the dominions of Spain in both hemispheres. Philip's patience being exhausted, he prepared a mighty armament for the invasion of England. A complete account of this famous attempt to plant a foreign standard on our shores, and its disastrous termination, will be found in the article ENGLAND. A second expedition for the invasion of Ireland shared the fate of the former; and this effectually cured Philip of all ambition to attempt the subjugation of the most hated of his enemies.

The revolt of the Moriscos occupies a remarkable place in the native annals of the sixteenth century. These Christianized Moors still remained Mahommedans at heart, making amends for compulsory apostasy by celebrating in secret the rites of their religion. It was the jealous policy of Spain to destroy, if possible, every vestige of their nationality. To effect this end the government had recourse to severe and unjust measures, which produced open revolt and civil war in Granada. Dreadful atrocities were committed by the Moriscos, and fierce was the retaliation of the Christians. The war raged with various success for some time, but how the struggle must terminate could never for a moment be doubtful. The Moriscos fled to the mountains, the ancient asylum of liberty; and in the deep caverns with which they abound they deemed themselves secure. But thither they were hunted by the Christians, and, like wild beasts, smoked to death by fires kindled at the mouths of these subterranean retreats. All who were in arms were cut off in this manner, or by the sword. The total expulsion of the Moriscos, however, did not take place till a subsequent period. To some affairs of a private or more trivial nature it is unnecessary to advert, although some of them deeply implicate the character of Philip. This prince died in September 1598, in the palace of the Escurial, of which he was the founder, and which is the noblest monument of his reign. By the last of his four wives, Anne of Austria, Philip left a son, who succeeded by the title of Philip III.; his other male children preceded him to the tomb. Don Carlos, one of these, is generally believed to have been murdered by the command of his bloody and unrelenting father. The character of Philip was gloomy, stern, and cruel; he was suspicious, dark, and vindictive, the irreconcilable foe of civil and religious liberty, for which there can only be brought forward as a palliation his zeal for what he called religion. But Philip was eminently prudent, attentive to public affairs, and what he conceived to be the best interests of his country. It has been supposed that the sceptre of Philip was swayed over 100,000,000 of human beings, including the population of all the foreign possessions of Spain. At this time the state of the inhabitants of the Peninsula was one of comparative comfort. Agriculture, manufactures, and commerce, flourished to an extent even greater than in the best period of the emperor's reign. Yet all his vast resources, especially in the New World, were unhappily wasted by Philip; and his own policy destroyed the very foundations on which they rested, and hastened the decay, or rather ruin, of the kingdom. The measures which exercised so fatal an influence over the destinies of Spain may be briefly enumerated. 1. His persecution of the Flemings and Dutch, which led to a revolt that cost him 150,000,000 of ducats; 2. his war with England, no less expensive and disastrous; 3. the treasures sent to support the abominable Catholic league, and wars in other quarters; 4. the subjugation of the Moriscos, and the proceedings of the inquisition, by which the most productive and useful classes of his subjects were ruined or expatriated. From these and from other minor causes, notwithstanding the enormous revenues and resources of the kingdom, Philip died insolvent.

Phili II.

The greatness of Spain having passed away with Philip II., from this period it declined with fearful rapidity. For a long period there is little to be recorded beyond the reign of worthless favourites, the profligacy of courts, and the feeble efforts of a government struck with mortal paralysis. Our retrospect of these reigns will therefore be characterized by a brevity corresponding with their importance. The most signal event of Philip III.'s reign was the total expulsion of the Moriscos from all parts of Spain where they had sought a home during the struggle recorded in the last reign. The loss to agriculture and commerce, for they were by far the most ingenious and industrious portion of the community, and the blow which would be inflicted on the national prosperity by the withdrawal of so much wealth as they possessed, were never taken into account by the duke of Lerma, the prime ministers, nor any of his inquisitorial councillors. Orders were issued for their immediate expulsion in September 1609, and no fewer than 600,000 individuals were forcibly dragged from their homes, and landed on the African shore, there to be treated even worse, by the most cruel and perfidious of the human family. The foreign transactions of this reign are unimportant. Philip III. died in March 1621, leaving his kingdom to a son who bore his name, and also inherited his imbecility.

Philip IV.

Philip IV. ascended the Spanish throne in his seventeenth year. Profligate extravagance and dissipation soon began to characterize the proceedings of the court, and murmurs and complaints to agitate the people, who were exhausted of their wealth in supporting pantomime and mummery at home, and iniquitous wars abroad. The reins of government were surrendered into the hands of the Conde de Olivares, a worthless favourite. An attempt to enforce an obnoxious measure drove the Catalans to revolt. They sought and obtained the aid of France, and this occasioned a feeble and unimportant war, which languished till 1660, when peace was concluded, but not till Spain had surrendered part of her territory to France. Contemporary with the origin of the Catalan insurrection was that of Portugal, by which the Portuguese freed themselves from the Spanish yoke. See PORTUGAL. During his long reign, Philip was frequently at war with England, Holland, and France, and every power committed fearful ravages on his territories. England took Jamaica during this disastrous and disgraceful period of Spanish history. In Naples, a terrible shock was sustained in 1646, by the insurrection of Massaniello. See the article NAPLES. But the most calamitous of Philip's transactions was the war in the Low Countries, which terminated in his recognising the independence of the seven United Provinces. Philip died in 1665. His character needs no description. Since the days of Roderick the Goth, a more disastrous reign than his had not darkened the annals of Spain.

Charles II.

Charles II. son of Philip IV. succeeded to the throne when only four years of age. As the affairs of the kingdom were then situated, they were not likely to improve under a child; and it was a further misfortune, that throughout his long reign the king remained little better than a child. He was feeble in body, and next to imbecile in mind; in proof of which it may be mentioned, that he believed himself bewitched, and submitted to the exorcisms of his confessor with devout solemnity. Louis of France, who espoused Maria Teresa, sister of Charles II. by a prior marriage, in right of his wife preferred a monstrous claim to the Low Countries, and poured his legions over the frontier to make it good. The union of Sweden, Holland, and England, to oppose the ambition of the Frenchman, saved the whole Netherlands from subjugation; but by the peace of Aix-la-Chapelle Louis retained the most valuable of the conquests which he had made. In this reign the complete independence of Portugal was recognised. In 1672, France invaded Holland, now the ally of Spain, conquered Franche-Comté, which belonged to Spain, made some destructive inroads into Catalonia, and reduced some fortresses in the Low Countries. By the alliance against France, in which England, Germany, and Spain joined, Louis's career of ambition was effectually checked. But subsequently he reduced Valenciennes, Cambray, St Omers, and other places; Ypres and Ghent were assailed with equal success; and a place on the Catalan frontier also yielded to his arms. Most of these places, however, were restored at the peace of Nimeguen in 1678, one of the conditions of which was, that Charles should receive the hand of Maria Louise, niece of the French king. On the death of this princess in 1689, the French again poured the storm of war over the frontier of Catalonia. Destitute of money and of troops, Spain trembled to her most distant extremities. But circumstances of a delicate nature, into which we shall not enter, induced Louis to restore all his conquests at the peace of Ryswick in 1697. The health of Charles, always infirm, now rapidly declined, and he expired on the 1st of November 1700. He was the last of the Austrian dynasty; and glorious as the condition of Spain was under its early sovereigns, those who succeeded them had brought the kingdom to the verge of ruin. From the accession of the third Philip it had declined, from causes already specified.

History.

The condition to which it was now reduced was pitiable. The army and navy were in a state of utter disorganization; the walls of towns and fortresses were in ruins; the public revenues had dwindled to little more than a nobleman's income; and trade, manufactures, and commerce, had all but ceased to exist. Another such reign as that of Charles II. would have dissolved the bonds of society.

Philip V.

Charles II. was succeeded by Philip V. duke of Anjou, grandson to Louis XIV. of France. He was the eldest son of Maria Teresa, eldest daughter of Philip IV., consequently the most legitimate sovereign; for Charles left no issue, and before his death he had subscribed an instrument, declaring Philip his successor. The foreign events of this reign demand our first attention. The transactions of the war which was soon declared against France and Spain, by England, Holland, and the empire, assisted by Savoy, Portugal, and Prussia, have been already related under the article Britain. The chief objects of the alliance were to obtain satisfaction for the Austrian claims on Spain, the emperor Leopold being not only descended from Fernando, brother of Charles V., but whose mother was the daughter of Philip III.; to rescue the Netherlands from France; to prevent the union of the French and Spanish crowns; and to exclude subjects of the former from the Spanish possessions in the West Indies. The treaty of Utrecht, which terminated the differences between the principal contending powers, was signed in 1713; and in 1715 a permanent peace was concluded between Spain and Portugal. By the celebrated treaty of 1713, Spain was stripped of half her European possessions. Philip was indeed acknowledged king of Spain and the Indies; but Sicily was ceded to the duke of Savoy; Milan, Naples, Sardinia, and the Netherlands, to the emperor; and Gibraltar and Minorca to the English. The Catalans, who had revolted and joined the allies, were likewise guaranteed a general amnesty, but without any stipulations for the preservation of their ancient fueros or privileges, which they had justly forfeited. Philip also renounced, both for himself and his successors, all claims to the French crown. In return for this renunciation, he forced rather than persuaded his council to introduce a measure to which subsequent events in the history of Spain gave great importance. This was to alter the order of succession, and establish a sort of Salic law, by which the most distant male of the family would be called to the inheritance in preference to the nearest female. The innovation was regarded with discontent. By the ancient law, which, in default of direct male issue, called females to the throne, the monarchy had been formed. By it Catalonia had been united with Aragon, and the latter with Castille; and by it Philip himself had inherited the crown.

Philip made an unsuccessful attempt to recover Sicily, Sardinia, and Naples; for he had now rendered both his navy and his army formidable alike by discipline and numbers. His fleet, however, was totally destroyed off the coast of Sicily, by our Admiral Byng, in the year 1718.

By a new treaty in 1720, Sardinia was given to the duke of Savoy, and Sicily to the emperor; and by the treaty of Seville, concluded in 1729, the duchies of Tuscany, Parma, and Placentia, were ceded to Spain. In 1731, the Spanish king invaded Naples, took possession of that kingdom, and conferred it on his son Don Carlos, in consequence of which war was declared between Spain and the empire in 1733. At the end of that year the palace of Madrid was consumed by fire, and all the archives relating to the Indies perished in the flames. In 1739, hostilities were renewed between Spain and Britain; but the only successes obtained by the latter power were the capture of Porto Bello by Admiral Vernon, and that of the Manilla galeon by Commodore Anson. Philip's long and turbulent reign was now drawing to a close. In July 1746, he was hurried to the grave by an attack of apoplexy. One memorable event of his reign remains to be noticed. In imitation of the emperor, he resigned the cares of royalty into the hands of his son in 1724; but finding seclusion irksome, he resumed them again in a very short time. Whatever might be the weaknesses of this prince, he had a sincere desire for the good of Spain, and retrieved it from hopeless ruin by several judicious measures which he introduced, so that the country attained a degree of positive prosperity unknown since the days of the second Philip.

Fero nd VI.

Ferdinand VI. a mild, prudent, and beneficent prince, reformed abuses in the administration of justice and management of the finances. He revived commerce, established manufactures, and promoted the prosperity of his kingdom.

Cha III.

Charles III. succeeded Ferdinand in 1759. The famous family compact was concluded at Versailles in 1761, among the four kings of the house of Bourbon. The English, alarmed by the naval preparations of Spain, declared war in 1762, and took Havannah in the island of Cuba, and Manilla in the East Indies. Notwithstanding this success, peace was hastily concluded at Fontainebleau, in November, by which the Havannah was restored. In 1767 the Jesuits were expelled from Spain. An unsuccessful expedition was concerted against Algiers in 1775, the particulars of which it is unnecessary to detail. In the war between Great Britain and her American colonies, Spain, by the intrigues of the French court, was instigated to take up arms in support of the latter. At the conclusion of that calamitous war, Great Britain, in a treaty with Spain, ceded to this power East and West Florida, and the island of Minorca. Charles died in 1788, and was succeeded by his second son Charles Anthony, prince of Asturias, the eldest having been declared incapable of inheriting the crown.

Charles IV. had not long been seated on the throne before the portentous revolution in France involved Europe in a general scene of political and military contest. The king of Spain joined the general confederacy against the new republic, and in consequence was numbered among the objects of its resentment, by a declaration of war in 1793. The military operations of Spain, however, were extremely languid; and after two campaigns, in which she might be said to carry on rather a defensive than an offensive war against the republican armies, she was compelled to conclude a treaty of peace, which was signed at Basel on the 22d July 1795. By this treaty the French republic restored to the king of Spain all the conquests which she had made from him since the commencement of hostilities, and received in exchange all right and property in the Spanish part of St Domingo.

17

This treaty was soon followed by a rupture with Great Britain. On 5th October 1796, the court of Spain having published a manifesto against this country, the court of London made a spirited reply; and about the same time was published a treaty of offensive and defensive alliance, which had been concluded about two months before, between the king of Spain and the French republic. In the war which followed between Spain and Great Britain, his Catholic majesty could boast of but little honour or success; and the French republic gained little from its new ally but the contributions of money which it from time to time compelled him to advance. On the 14th of February 1797, a Spanish fleet of twenty-seven sail of the line was defeated by Sir John Jervis off Cape St Vincent, and four of the Spanish line-of-battle ships were left in the hands of the victors. From this time till the temporary cessation of hostilities by the peace of Amiens in 1802, there is nothing remarkable in the transactions of Spain.

179

180

On the renewal of the war in 1803, Spain was again compelled, by the overbearing power of France, to take an active part against Great Britain, and fitted out a formidable fleet, which was united to a considerable naval force belonging to the French. The Spanish declaration of war against Britain is dated at Madrid on the 12th of December 1804; and on the 21st of October 1805, the combined fleets of France and Spain were annihilated by Lord Nelson off Cape Trafalgar. After this terrible blow to the naval power of Spain, nothing of importance took place till 1808, when the liberties of Spain were subverted by the machinations of Napoleon. The designs of the French emperor, long suspected, became sufficiently apparent in 1808. Unfortunately the dissensions of the royal family of Spain were so favourable to his plans, that they may be said to have hurried on their execution. The dark and tortuous policy by which he effected his purpose, and the course which events took in Spain, will be found detailed in the article FRANCE, so that only a brief notice of the leading facts will be given in this place. At this time (1807) the management of state affairs was in the hands of Don Manuel Godoy, the favourite of Charles IV. and his queen, and better known by the name of the Prince of Peace. He had been raised from the humblest station to be the richest and most powerful subject in the kingdom, and to fill its highest posts. Ferdinand, the prince of Asturias, had refused to marry the sister-in-law of this fortunate minion, and to secure himself from his vengeance he wrote to Napoleon asking for protection. At the same time he exposed the administration of Godoy, in a letter to his father, and requested to be allowed some participation in the government. This so enraged the queen that she ordered his immediate arrest; but, on asking pardon of the king, Ferdinand was restored to liberty, not however before Charles had taken the fatal step of appealing to Napoleon regarding his son's supposed treasonable conduct. The emperor of France was thus constituted umpire between father and son. French troops poured into Spain, which was thrown into a ferment by the rumour that the royal family were preparing to fly to America. Popular indignation was kindled against the hated favourite, who narrowly escaped with his life. At length Charles abdicated in favour of his son, but two days afterwards privately protested against his own act, and sent a copy of this strange paper to Napoleon, who afterwards made it a pretext for his ulterior designs.

Ferdi nd VII.

The prince of Asturias, now elevated to the throne under the title of Ferdinand VII. made his triumphal entry into Madrid. Shortly afterwards he was induced to undertake a journey to Bayonne to meet Napoleon, and consult about the affairs of the kingdom. This memorable interview took place, and the eyes of Ferdinand were now thoroughly opened to the designs of the French emperor, by finding himself a captive in his hands, and his right to be considered king of Spain rudely denied. The rest of the royal family eagerly rushed into the snare set for them by the master of toils at Bayonne. Here father and son surrendered the crown of Spain into the hands of Napoleon, by whom it was transferred to the head of his brother Joseph. But such a momentous event as a change of dynasties, effected under circumstances of such atrocious perfidy, could not take place without rousing every loyal and every indignant feeling in the bosoms of the Spanish people. No sooner was the fact of the renunciation known, than the northern provinces burst into open insurrection. Asturias and Galicia set the example; and it was soon followed by almost every part of Spain not immediately occupied or overawed by the armies of France. One of the first steps taken by the leaders of the insurrection was to assemble the juntas or general assemblies of the provinces. When these were organized, they issued proclamations, calling on the Spaniards to rise in defence of their sovereign, and in the assertion of their own independence. Besides these proclamations from the provincial juntas, addresses were published in almost every province by the leaders of the popular cause; in particular, the province of Aragon was addressed by Palafox, a name celebrated in the annals of the Spanish revolution, in a bold and spirited manifesto. The junta of Seville, which assembled on the 27th of May, formed itself into a supreme junta of government, caused Ferdinand to be proclaimed king of Spain, took possession of the military stores, and issued an order for all males from sixteen to forty-five, who had no children, to enroll themselves in the national armies. On the 4th of July the alliance of Great Britain with the Spanish nation was proclaimed, and a struggle began which terminated in the complete expulsion of the French from the Peninsula. The events of this celebrated war will be found recorded in the article BRITAIN.

The loss of the royal family, by which they were deprived of a directing power, a legitimate head to give the constitutional stamp to their proceedings, plunged the Spaniards in great difficulties. Unity of opinion was wanting to the junta, and vacillation and weakness marked its proceedings. It was unfortunate, that while one spirit animated the mass of the people against the French, many of the nobles and other influential individuals had given in their adhesion to the French dynasty. The successes of the latter were attributed, probably not without some reason, to treachery; and more than one Spanish general fell a victim to public indignation, whether justly or unjustly cannot now be known. But whatever victories the French gained, they only remained masters of the places which they occupied. A vast system of guerilla warfare had been organized and vigorously prosecuted, which served to preserve the energy and confidence of the nation unbroken. The guerillas everywhere surrounded and harassed the French; no line of communication was safe for them. These petty achievements, however, could not compensate for the loss of battles on a large scale, and the capture of fortresses, the strongholds of the kingdom. The supreme junta fell under suspicion, and, unable to sustain the weight of government and the storm of public indignation, it was agreed that the Cortes should be convoked, and a regency appointed. The manner in which this celebrated Cortes was constituted has been a subject of keen disputation; but the circumstances in which the kingdom was placed at the time, rendered it impossible for the members being chosen according to the ancient forms. It has been alleged that this assembly was of a much more popular and democratic nature than the regular Cortes, which is undoubtedly the fact. It ought to be recollected, however, that the nobles were a suspected body, and therefore the burgesses and others might consider it dangerous to admit their voice in a matter which involved the liberties of the kingdom. But, we repeat, the situation in which Spain stood at this eventful moment made it a matter of necessity for those who directed the affairs of the nation, to act as they did. Had not the progress of the French armies dispersed the central junta, and concentrated the fugitive patriots at Cadiz, it is more than probable that the Cortes would have been assembled according to the ancient forms, and that the privileged classes, supported by the majority of the nation, would have defeated any attempt to alter the old constitution. But Cadiz offered to that party which has been since known by the name of liberal, the most favourable opportunity of striking a deadly blow at the very root of the monarchical power under which they had so long groaned in hopeless yet silent restlessness. Cadiz was not only in itself a place much more democratic than any other in Spain, but during the usurpation of the French it had become the asylum of all who professed liberal principles. As they generally belonged to that numerous class of the Spanish gentry who look up to the patronage of government for the means of subsistence, the court drew them together from the provinces. On the prospect of the political changes which the captivity of Ferdinand opened to the country, these men attached themselves to the central junta, and finally followed its members in their flight from

Seville to Cadiz. Hither, too, flocked all the stragglers of the philosophical party; and on the dissolution of that dull, dilatory knot of ill-assorted men, who, under the veil of dignified gravity, had for a time concealed their unfitness to direct the nation, the Spanish speculatists found themselves in the midst of a population highly disposed to listen to their doctrines, to approve their views, and constitute them the organs of the new laws which were to remodel the kingdom.

New constitution.

The majority of the first Cortes being composed of liberals, the project of a constitution was immediately set on foot, and a committee of the ablest members appointed to draw up the fundamental code of the monarchy. Such a task, at all times arduous, was, in the present circumstances of the country, beset with peculiar difficulties. Encouraged by the absence of the king, placed beyond any check from the privileged classes, and the weight of the landed property of the country, it is not surprising that the framers of the constitution allowed their zeal to carry them too far, especially when it is considered that the Spanish people were almost entirely unaccustomed to the exercise of civil rights. The government was wholly remodelled, so that from being the most absolute monarchy in Europe, it became the most strictly limited of all limited monarchies. As this constitution, with the exception of a few alterations, is nearly the same as that which is now in force, our introducing it in this place will serve to give greater clearness to the subsequent narrative of events. It was drawn up by 184 members of Cortes, on the 18th March 1812. On the 20th of the same month the regency, which consisted of Cardinal Bourbon and two other apparently incapable individuals, took the oath to maintain it. This constitution was acknowledged by the allies of Spain, namely, Great Britain, Sweden, Denmark, Prussia, Russia, and other states.

By one of the first articles in the code, the sovereignty is declared to reside essentially in the nation, which, being free and independent, neither is nor can be the patrimony of any person or family. All Spaniards, without distinction, are subject to taxation. "The religion of the Spanish nation is, and shall be for ever, the Catholic, Apostolic, and Roman, which is the only true religion." "The nation," it is added, "protects it by wise and just laws, and forbids the exercise of any other whatever." The government of the Spanish nation is stated to be "a limited hereditary monarchy." The power of making laws is vested "in the Cortes, jointly with the king." In describing the class of Spaniards who enjoy the privileges of citizenship, persons "reputed of African origin, either by the father or the mother's side," are excluded. A similar exclusion is given to Spaniards who obtain naturalization in another country, or who, without leave, absent themselves five years from Spain. The only basis for the number of representatives in the Cortes is *population*, to be taken from the census of 1797, till one more correct can be made. For every seventy thousand souls there is to be one deputy in the Cortes. The returns of the members are made by three successive elections. Every parish appoints electors for the district to which it belongs. These repair to the chief town of the district to choose another set of electors, who, lastly, meeting in the capital of the province, make the final appointment to the Cortes. The Cortes are triennial. No member can be elected for two successive representations. No debate can be carried on in the presence of the king; his ministers may attend and speak, but are not allowed to vote. There is a permanent deputation, or committee of the Cortes, composed of seven members, appointed by the whole body, before a prorogation or dissolution, whose duty is to watch over the executive, and report any infringement of the constitution to the next Cortes. It also belongs to them to convoke an extraordinary meeting of the Cortes in the cases prescribed by the constitution.[1]

The powers of the Cortes are chiefly these: 1*st*, To move and pass the laws, and to interpret and alter them when necessary; 2*d*, to administer the constitutional oaths to the king, the prince of Asturias, &c.; 3*d*, to determine any doubt or fact relative to the succession; 4*th*, to elect a regency, and define its power; 5*th*, to make the public recognition of the prince of Asturias; 6*th*, to appoint guardians to the king while a minor; 7*th*, to approve or reject treaties previous to ratification; 8*th*, to allow or refuse the admission of foreign troops into the kingdom; 9*th*, to decree the creation or suppression of offices in the tribunals established by the constitution, as well as of places of public trust; 10*th*, to fix, every year, by the king's proposal, the land and sea forces; 11*th*, to regulate the military code in all its branches; 12*th*, to fix the expenses of the government; 13*th*, to impose taxes, contract loans, and direct every thing relating to the revenue; 14*th*, to establish a plan of public instruction, and direct the education of the prince of Asturias; 15*th*, to protect the *political* liberty of the press; 16*th*, to enforce the responsibility of the secretaries of state, and other persons in office.

Laws may be proposed, in writing, by any one of the deputies. Two days after the motion, the bill is to be read a second time. It is then determined whether the subject is to be debated, or to be referred to a committee. Four days after the bill has been voted worthy of discussion, it is read a third time, and a day is appointed for the debate. A majority of votes decides the fate of the bill; the members present on these occasions must exceed half of their total number by one.[2]

The powers of the king are, 1. To suspend the passing of a law, by withholding his sanction. He can exercise this power against any decree of the Cortes for two consecutive sessions; but is compelled to give his assent if the same law is passed by three Cortes successively. 2. The executive power resides exclusively in the king, and extends to whatever relates to the preservation of public order in the interior, and to the external security of the state, according to the constitution and the laws. The privileges and duties of the executive are thus detailed in the constitution. The king may issue decrees, regulations, and instructions, for the more effectually enforcing of the laws; it is his duty to watch over the administration of justice; he declares war and makes peace, under the control of the Cortes; he appoints judges to all the civil and criminal courts, on the presentation of the council of state; all civil and military employments are of the king's appointment; he presents to all bishoprics, ecclesiastical dignities, and benefices which may be in the gift of the crown, all by the advice of the council of state; the king is the fountain of honour; the army and the navy are at his command, and he has the appointment of generals and admirals; he has the right of coinage, and the privilege of impressing his bust on the metallic currency of the realm; the king can propose new laws, or amendments to those in existence. It belongs also to him to circulate or withhold the pope's rescripts and bulls. He can choose and dismiss his own ministers.

The following checks are imposed on the king's authority by the constitution.

1. The king cannot prevent the meeting of the Cortes at the periods fixed by the constitution, neither can he dis-

---

[1] The Cortes were separated into two bodies in 1836, and the election was made direct, not indirect.

[2] Some alteration in the powers of the sovereign was made in 1836, when this constitution was adopted. It was then decided, that the crown should have an absolute veto in the enactment of laws, and should likewise have the power of convoking, proroguing, and dissolving the Cortes; but in the latter case to be under the obligation of assembling others within a given time.

solve them or disturb their sittings; his advisers and abettors in such attempts are guilty of treason. 2. If the king should quit the kingdom without the consent of the Cortes, he is understood to have abdicated the crown. 3. The king cannot alienate any part of the Spanish territory. 4. He cannot abdicate the crown in favour of his successor without the consent of the Cortes. 5. He cannot enter into any political alliance, or make commercial treaties, without the consent of the Cortes. 6. He cannot grant privileges or monopolies. 7. The king cannot disturb any individual in the enjoyment of his property, nor deprive him of his personal liberty. If the interest of the state should require the arrest of any individual by virtue of a royal order, the prisoner must be delivered over to a competent tribunal within eight and forty hours. 8. The king cannot marry without the consent of the Cortes; he is supposed to abdicate the crown by taking a wife against their will.

The council of state is composed of forty individuals, viz. two bishops, two priests, and four grandees; the other thirty-two must not belong to any of these classes. The members of the council of state shall be chosen by the king, out of a triple list presented to him by the Cortes. The councillors of state cannot be removed without a trial before the supreme court of justice. Their salary is fixed by the Cortes. The functions of this council of state are to advise the king on all important matters of government, and especially upon giving or refusing his sanction to the laws, declaring war, or making treaties. The king, besides, cannot bestow any ecclesiastical benefice, or appoint any judge, but at the proposal of the council of state, who, upon every vacancy, are to confine his choice to one out of three individuals, whose names they are to lay before his majesty.

The laws for the security of personal liberty are these: 1. No Spaniard can be imprisoned without a summary process, in which he is credibly charged with the infraction of some law that subjects the offender to corporal punishment; 2. the arrest cannot take place without the warrant of a competent judge; 3. prisoners are not to be examined upon oath; 4. the gaoler shall keep a register of the prisoners, expressing the warrant, and the alleged cause of his confinement.

The rapid series of misfortunes which had shaken the imperial throne of France to its foundations opened the way for the return of the captive Ferdinand to Madrid. The constitutionalists looked forward to his appearance in the country with no favourable eye, and the arrival of despatches from him to the regency threw them into great consternation. Ferdinand announced that he had concluded a treaty with Napoleon. This assumption of absolute power on the part of the king, without the knowledge of the Cortes, was aiming a direct blow at their authority, and violating the constitution recently established; and they accordingly rejected the treaty. They likewise suspended the king from the exercise of all power till he should take the oath which the new constitution prescribed. He entered the Spanish territory on the 24th of March 1814, and took up his residence at Valencia. On his way he had not been slow to discover that the lower orders were in general indifferent to the constitution. The fact is, the new political principles had scarcely struck root among the people; and with a very considerable party, consisting of grandees, dignitaries of the church, and others, the king was still absolute, and these flocked around their master. In the Cortes itself there was a strong body opposed to the new order of things. A petition, signed by sixty-nine members, was presented to the king, in which the Cortes was described as a mere tool in the hands of a republican party, without freedom of debate, and acting under the control of a mob regularly hired to take possession of the galleries. Nothing, therefore, could be more favourable to Ferdinand's resuming absolute power. Accordingly, on the 4th of May 1814, a decree was solemnly promulgated, in which the Cortes were declared illegal, and all their laws consequently rescinded. Some of the leading members were arrested, as a prelude to what was shortly to happen. Under their usual leaders, the priests, the lower orders broke out into fierce demonstrations of joy when the news of these events reached the chief towns, and the king proceeded in a sort of triumph to Madrid. Further arrests of the deputies of the late Cortes took place; property was sequestrated and papers were seized; judges were appointed to try obnoxious members; but justice proving too tardy for the king's eager spirit of revenge, he himself pronounced sentence on the prisoners in a wholesale manner, in open defiance of all law and justice. A few were capitally punished, and a great many more were consigned to dungeons. The inquisition was restored, and was urged to exert its powers against all persons suspected of liberal opinions. Monks became once more the sole directors of the king's conscience, and the reign of absolutism and bigotry was completely restored.

But these arbitrary acts roused the dormant spirit of the Spanish people, and a revulsion of feeling was the consequence. In vain did the court party silence the press or bribe it into their service; facts which could not be concealed from the people daily pleaded the cause of liberty. Bribery and venality were soon observed to prevail around the throne; the treasury was completely drained, and the army remained unpaid; while, to add to the difficulties and dangers of Ferdinand's position, armed bands of guerillas, now become organized banditti, swarmed over the country, setting the helpless magistrates at defiance, and committing all sorts of atrocities. Free-masonry was abolished, and effectually kept in check; but a far more dangerous society, the members of which assumed the name of *Comuneros*, was secretly formed, and, in spite of the inquisition and its emissaries, held meetings in most of the principal towns, and kept up an active correspondence among their lodges. The constitution was publicly burned; but this served only to spread disaffection, and to give it an importance in the eyes of the people which it did not formerly possess. Cadiz having been fixed on as the head-quarters of the liberals, a regular plan for the overthrow of the government was there formed, and its secret influence was extended throughout the provinces. Our limits do not permit us to mention the numerous conspiracies which were discovered, and quenched in blood. They were sufficient to alarm any monarch but one wholly abandoned to the guidance of weak, wicked, or fanatical counsellors. Those who ventured to remonstrate with the king were banished or thrown into prison. The promise which he had made of granting a constitution founded on liberal principles remained unfulfilled, and for six years (1814-1820) Ferdinand reigned with absolute power. During that time there had been no less than twenty-five changes in the ministry, mostly sudden, and attended with severities. They were produced by the influence of the *camarilla*, or individuals in the personal service of the king. Every attempt to save the state was frustrated by such counsellors; and the overthrow of the government, now apparently inevitable, became accelerated by the loss of the American colonies.[1]

The army was the instrument of its fall. Amongst the officers several conspiracies had been organized for the restoration of the new constitution, at the head of which were

---

[1] It is unnecessary to do more in this place than merely allude to the revolution in the Spanish colonies of South America, which broke out in 1808, and finally terminated in the achievement of complete independence. Under the heads MEXICO, PERU, PLATA, &c., the revolutions in the various provinces will be found described.

Porlier, Mina, Lacy, and Vidal. Mina had succeeded in making his escape, but the others were taken and executed, their friends at the same time being put to the torture or thrown into prison. But these severities had no effect in repressing the discontent of the army; for the cause which immediately produced it was not removed,—the arrears due to the troops still remained unpaid. The money which might have been employed for this purpose was foolishly lavished in fitting out an expedition to destroy the liberties of the revolted South Americans: by a singular destiny it became the instrument of the overthrow of despotism at home, and the restoration of Spanish freedom. The troops which were to embark in the autumn of 1819, were indisposed to the American service; and the officers, favourable to the constitution of the Cortes, took advantage of this state of feeling to effect their own purposes. Whole regiments had determined not to embark; and the commander himself, O'Donnel, count del Abisbal, was in the secret. But he basely betrayed the cause, and had the principal conspirators arrested in front of the troops. For this devotion to despotism he was rewarded by the court party by being removed from the command of the expedition. Such ungrateful conduct towards a man who had forfeited his honour to save them, could not fail to bring the *Serviles*, as they were designated, into general contempt. A favourable opportunity soon occurred for the liberals carrying into execution the same plan which had failed through the perfidy of O'Donnel. The yellow fever having made its appearance at Cadiz, the safety of the troops which were there assembled demanded that they should be removed to some distance, thus leaving the members of the secret societies and other patriots at liberty to prosecute their schemes without fear of violent interruption. The embarkation of the troops had been fixed for January 1820; but on the first of that month, Riego, who had been placed at the head of the insurrection, gained over several battalions, and proclaimed the constitution of 1812. He arrested Calderon, the successor of O'Donnel; and finally joining Quiroga, a liberated patriot, and at the time in command of some troops, the combined force, amounting to 5000 men, marched on La Caracea, which was occupied. They had previously taken possession of La Isla. But still the country showed no disposition to second this bold movement of the army. In vain Riego led a flying column through the provinces, proclaiming the constitution, and expecting support from the inhabitants; few or none joined him. But several fortunate circumstances which occurred at this time materially contributed to the success of the insurrection. Mina, who had been obliged to fly to France, entered the Spanish territory of Navarre on the 25th of February, and a numerous band immediately surrounded his standard. Risings simultaneously took place in different quarters in favour of the constitution, which was publicly proclaimed in Galicia, Saragossa, Valencia, Murcia, Granada, and many other places. General Freyer, who had been appointed to the command of the troops in Seville, was himself obliged to publish the constitution in that city.

These insurrections could not fail to appal the weak, ignorant, and unpopular party which surrounded the throne. Ferdinand himself saw no general of sufficient ability or loyalty to be trusted with the command of a large army, which could soon have been concentrated, for there still existed fidelity among a sufficient number of the troops. It was however an expiring feeling, which could only have been re-animated by a great leader, but which, in the present destitution of the country, a mere breath might extinguish. And it was extinguished. Ferdinand was abandoned by his troops. Even O'Donnel, who had acted the part of traitor to the liberal cause, became one of its principal supporters. At Ocana he proclaimed the constitution; an event which produced a great sensation in Madrid. The royal palace was surrounded by a crowd, who called on Ferdinand to accept the constitution, and he now found that no alternative was left to his choice. The humbled monarch appeared at the balcony, holding a copy of the constitution in his hand, as a pledge of his readiness to swear to its observance. This occurred early in March 1820. To give efficacy and legality to the restoration of the constitution, it was necessary that the Cortes should be convoked, and the oath of the king to uphold the new order of things taken in their presence. The Cortes assembled on the 9th of July, and all the formalities were regularly observed. Meanwhile the constitutional system had been put into complete operation. During its proclamation at Cadiz, a bloody and disgraceful transaction took place; some of the royal troops present wantonly fired on the unarmed multitude, and about 500 were killed or wounded. The inquisition was abolished, as inconsistent with it, the state-prisoners were liberated, and new ministers were appointed. In place of the Council of Castille, and that of the Indies, a supreme judicial tribunal, with appropriate subordinate courts, was established; national guards were organized in the provinces, and the municipal authorities were made to conform to the constitution.

The meeting of the Cortes of 9th July, and their subsequent proceedings, mark the establishment of a new order of things, destined however to be of short duration. This assembly acted with extreme moderation, the measures of retaliation being infinitely less severe than those which followed the king's triumph over the constitution. The members strove to temper the violence of the liberals, and endeavoured to restore the *afrancesados* (those who took the oath to support the French dynasty) to their rights, to counteract the machinations of the serviles, and to heal the wounds of the country. But some of their proceedings were characterized by less judgment and humanity. The suppression of many of the convents and of the *majorates*, the banishment of the nonjuring clergy, and some other of their measures, excited discontents. Various parts of the country became disgraced by popular excesses, while on the frontiers of Portugal the royalist party formed a junta for restoring the privileges of the crown and the church. Conspiracy and openly avowed disaffection to the new order of things spread so widely, that when the second session of the Cortes opened in April 1821, the country was declared to be in a state of danger. The command of the army having been intrusted to Morillo, quiet was in some measure restored; but still it was found necessary to summon an extraordinary meeting of the Cortes in September. Spanish affairs in America had now assumed their gloomiest aspect; and the government wished to compromise the matter by acknowledging America as a kingdom independent of Spain, but united with her under a common sovereign, Ferdinand VII. Such an absurd proposal was rejected with scorn. The absolutists, although beaten everywhere by the troops of the government, could not be entirely suppressed; and even the adherents of the constitution began to complain of the weaknesses and mistakes of the ministry. The Cortes requested the king to appoint abler men; and to this he reluctantly yielded in 1822. Notwithstanding the errors of the Cortes, considering that the king was with them, and that his brother Carlos, although approving of the conduct of the absolutists, had not ventured to join them, it is probable that the struggles, after continuing for a few years, might have ended in a compromise, had not the whole power of France been thrown into the scale of the serviles.

The events which immediately preceded Ferdinand's restoration to absolute power, and the complete annulment of all the acts of the Cortes, were so various and complicated, that, if fully detailed, they would of themselves more than occupy all the space within the limits to which this outline of Spanish history must be confined. Into particulars, therefore, we shall not enter; only the most important transactions can be noticed. Disaffection to the government in the southern provinces, where a strong body of French troops was stationed as a sanitary cordon during the prevalence of pestilence in Spain, terminated in open revolt. The national guards were called out to suppress it, and they were everywhere victorious; but the pecuniary resources were chiefly in the hands of the supporters of despotism. In Madrid an occurrence took place in July 1822, which threatened the most disastrous consequences. This was a daring attempt of the friends of absolute government to overthrow the constitution. They were supported by the royal guards, while the national guards were ranged on the popular side. A conflict took place, in which nearly the whole of the royal guards were cut off. But insurrection, although thus suppressed in the capital, still prevailed to an alarming extent in Biscay, Navarre, and Catalonia, where armed bands, under the name of apostolical troops, *feotas*, or soldiers of the faith, committed revolting cruelties. Near the French frontier, and probably under French influence, the absolutists appointed a regency, which issued orders in the name of the "imprisoned" king, as they thought fit to call Ferdinand, although he had recently, under no compulsion, but in the most voluntary manner, again declared his adherence to the constitution. The avowed object of this regency was the restoration of every thing to the state in which it had been prior to the 7th of March 1820. But this band of outrageous serviles, unsupported by the nation, was compelled to fly to France in November 1822. The foreign relations of Spain now fell into a state of dreadful disorder; and the principle of armed intervention pronounced by Austria, Russia, and Prussia, in relation to this unhappy kingdom, was threatened to be acted upon by France. The restoration of Ferdinand to the full enjoyment of sovereign authority was demanded by the four powers named, while England advised the Cortes to yield, and offered her mediation. But the Spanish government repelled with indignation this attempt of foreign powers to interfere in its affairs. The consequences were the recall of the foreign ambassadors by their respective courts, and the march of 100,000 French soldiers across the Bidassoa. The duke of Angouléme, by whom this army was commanded, established a junta, consisting of Eguia, Calderon, and Erro, who formed a provisional government, declaring the king the sole depositary of sovereign power, and that no change in the government should be recognised but such as the king should make of his own free choice. All the decrees of the Cortes were declared void; in short, the object of French interference was simply to restore the reign of absolute power. Unfortunately the Cortes had no ally. The relations of Portugal to Great Britain did not allow her to conclude a defensive treaty with Spain. Britain remained neutral; but the exportation of arms and ammunition to Spain was allowed, and, in parliament, Canning called the attempt of the French unjust, and wished the arms of the Cortes success; an expression of sympathy which led the Spaniards for a time to hope that Britain would take a part in the war. Ferdinand, for greater safety, had removed to Seville, and on the 23d of April 1823 he formally declared war against France; but he in vain called on the nation to support the constitution. The great mass of the people were completely under the influence of the most bigoted priesthood in the world, who of course were absolutists, and hailed the arrival of the French; the adherents of the constitution were confined to the educated class, the army, and the inhabitants of cities. The Spanish army might be equal in strength to that of the French, but a considerable part of it was disposed in garrisons and fortresses, scattered over a large surface of country. The military operations of the French, during their advance upon Madrid, were the siege and capture of several strong towns, and a few partial engagements, in one of which, at least, that of Logroño, they were defeated. The southern provinces, where the absolutists had always a preponderancy, were occupied by the invaders with hardly any resistance; but in Lower Catalonia, where Mina commanded, they were kept in check for a considerable time. The main body of the French army under Angouléme hastened to the capital, which was occupied on the 24th of May. One of the first steps taken was to appoint a regency, which put every thing on the same footing as before March 7, 1820. But the regency had no pecuniary resources, and no power, if they had the will, to prevent the furious ebullitions of party hatred. The Cortes had in vain tried to excite a general guerilla war; it was but too plain that the mass of the people, at once miserably ignorant and furiously bigoted, without any just notions of what rational liberty was, or in what the new constitution consisted, were content to surrender themselves entirely to the guidance of the priesthood, and consequently everywhere opposed the constitutionalists. Their hatred was still further increased by the seizure of all the property of persons of the opposite party, by a large forced loan, and by the coining of the superfluous church plate, to which measures the want of money compelled the Cortes to have recourse. The war had now spread from the south to the north over the whole breadth of the land, and was actively prosecuted in Andalusia and Estremadura. An attempt at mediation on the part of the English ambassador, Sir W. A'Court, failed; and the king having refused to go to Cadiz, the Cortes, acting on that part of the constitution which provides for the moral incapacity of the sovereign, appointed a regency with royal powers. We cannot regard this proceeding in any other light than as a gross indignity offered to the king, and most impolitic at the time. However, Ferdinand accompanied the Cortes to Cadiz, and the regency ceased to exist. On the other hand, the members of the Cortes who had declared the king morally incapable, were denounced as traitors by the regency of Madrid, which now became recognised by foreign powers, Austria, Prussia, and France, as the only legitimate government of Spain.

Meanwhile the war was briskly carried on, but nothing would induce the people to join the constitutionalists, who accordingly were gradually driven from stronghold to stronghold, although in some places they made a gallant resistance. Defection among the officers of the army materially contributed to the downfall of their cause. Morillo and Sarsfield were among the deserters. The regency of Madrid conducted themselves in a cruel and outrageous manner towards the friends of the constitution, notwithstanding the strenuous efforts of the French generalissimo to restrain their fury. The duke of Angouléme took possession of the city of Cadiz on the 4th October 1823. Previously to this, the Cortes had reinvested Ferdinand with absolute power, and requested him to remove to the French head-quarters, where he was received with becoming pomp. The first measure of the king was to declare all the acts of the constitutional government from March 7, 1820, to October 1, 1823, null and void, on the ground that during that period he was acting under compulsion. The war terminated in November; and on the 22d of that month the duke of Angouléme took his leave of the army of the Pyrenees. Among the crowds of fugitives were Mina and the count of Abisbal; and among the victims capitally punished was Riego, who suffered at Madrid on the 6th of November.

The party which now succeeded to power, although weak from want of means, was powerful enough to exercise a persecuting and vindictive policy towards the former partisans of the constitution. The French wished to secure mildness and moderation, but the bad faith of the Spanish government frustrated these objects. To restrain the violence of party fury, which so widely prevailed, a treaty was concluded with France, by which that power agreed to maintain a large military force in the country, until the Spanish army could be organized. This was certainly a wise measure in the circumstances; for Spain, if left to itself, would probably have fallen into irretrievable confusion. It was divided by two parties, who mortally hated each other; and the bonds of society, already shaken loose by years of war and unrestrained licentiousness, required little more to dissolve them altogether. The reports from the provinces were appalling; the treasury was empty; home and foreign credit were alike destroyed; and trade and commerce were paralyzed. The personal moderation of the king led to the formation of a plot by the absolutists, to compel him to abdicate, and to raise his brother Carlos to the throne. This was the origin of the Carlists, who make so conspicuous a figure in the sequel. An attempt to restore the inquisition was happily frustrated. In May 1824, a decree of amnesty appeared; but it was a mere mockery, for it contained so many exemptions, that those who were to enjoy its benefits seemed rather to form the exception than the rule. The year 1825 was disturbed by several insurrections of the Carlists, which were attended with numerous executions. The independence of the American colonies was recognised by foreign powers, but Spain herself did not acknowledge it till the year 1836. The general interruption of commerce and industry, with the flight of many persons of property, occasioned much distress. The disturbances continued for some years, attended with the same marks of feebleness on the part of the government, and a continuance of general distress. It was a period of terror for the liberals, who were plundered and imprisoned on the slightest pretexts. The army, purged of all officers suspected of liberalism, was recruited by a motley throng of adventurers, friars, smugglers, mechanics, publicans, and muleteers, who had been officers in the guerilla bands of Catalonia and Navarre. The ranks being replenished in this manner, the French troops were enabled to evacuate Spain in 1828. Some insurrections, which had broken out during the preceding year, were suppressed without much trouble; and in spite of the arbitrary rule of the Carlists, their tortuous policy, and their open violence, the country began to show some symptoms of improvement.

In May 1829, Ferdinand lost his queen, and on the 9th of November following, her place was supplied by a Neapolitan princess, Christina Maria. Unblessed with issue by his three former marriages, the hope and the desire of having a child of his own to inherit his honours and preserve the throne to his dynasty, probably hastened the nuptials of Ferdinand. The French revolution of 1830 caused much less sensation in Spain than might have been expected. The fact is, the liberal party had been so devoured or dispersed by the sword, the scaffold, exile, and the dungeon, that in the country itself it was not powerful; but a rash and ill-judged attempt in the constitutional cause was made from without. General Mina assembled a body of refugees and others, and invaded the Basque provinces; but they were speedily repelled, and sought refuge in France. Meanwhile, some events of momentous importance had taken place in the royal family. The Infant Don Carlos was presumptive heir of the throne; the succession to the Spanish crown had been subjected to the Salic law by Philip V., so that, as matters stood at present, no daughter of the reigning king could interrupt its descent to his brother. The queen of Ferdinand was about to make him a father, and in order to secure the crown to his own child, should the issue prove a female, he resolved on revoking the Salic law, which excludes females. It is important to observe, that, in 1789, Charles IV. issued a pragmatic sanction, having the force of law, and establishing the regular succession to the crown of Spain in females as well as males. The Cortes of 1812 likewise solemnly revoked the law of Philip V., and re-established the old law of the Partidas. But as Ferdinand had annulled the acts of that assembly, and as the decree of Charles IV. might be cavilled at by the fierce and intolerant party who wished that Carlos should succeed to the throne, the king obtained the records of the Cortes of 1789 regarding the succession, and on the margin opposite the decree of Charles IV., with his own hand, wrote a decree to the same effect. The minister, Calomarde (a Carlist at heart), remonstrated with the king against its publication; but Ferdinand was firm, and ordered the resolution to be carried into effect. In compliance with this demand, the whole was forwarded to the council; and in the gazette of the 6th of April 1830, the edict was published to the world. It was likewise regularly proclaimed in the streets of Madrid with the usual formalities. Ferdinand's foresight was justified. The infant with which the queen presented him was a daughter, born on the 10th of October, and christened Isabella Maria Luisa.

But the Carlists did not wait for the expected birth of the heir to the throne to show how terribly the publication of the decree had staggered them. They rushed into hasty plots against the government, which were detected before they were ripe for execution; and in various ways showed their chagrin and irritation. In order to render the succession still more secure, Ferdinand called a meeting of the Cortes, before which the edict of Philip V. was again repealed, and his daughter, the Infante Isabel, recognised as princess of the Asturias. An insurrection broke out in Cadiz in 1831, at the head of which was General Torrijas. It was soon quelled, and the leader, with fifty-three companions, fled to Malaga, where they were taken prisoners, and all shot in cold blood. The other events of this year are unimportant, with the exception of a sudden illness of the king, which so excited the hopes of the Carlists, that they strenuously urged their master to take advantage of the circumstance, and at once seize the crown. This remarkable fact shows with what spirit they were animated. It was not a love of justice, but ambition, and a spirit of vindictive hostility to the constitutionalists, who now began to be tolerated, that instigated them to attempt the exaltation of Carlos to the throne, and that at all hazards, even before he possessed the semblance of a claim to it; for while Ferdinand lived, by what right could he grasp at his sceptre? Yet his partisans extol his magnanimity in refusing it at this time.

In the course of the year 1832, Ferdinand had an alarming relapse of his disease, during the paroxysms of which a transaction took place of the utmost importance in itself, and which has been very differently represented by different parties. It was the signing of a decree by which he restored the Salic law to full operation, and the further confirming the disinheriting of his daughter, by annulling his testament in her favour. It is certain that the ministers strenuously urged him to adopt this measure; and that they were under Carlist influence, is no less certain. Every thing was accomplished to their wishes; the document was signed and properly secured, and the king appeared to have fallen into the sleep of death. His dissolution indeed was announced; but, contrary to all human expectation, the disease took a favourable turn; all symptoms of immediate danger disappeared, and consciousness and understanding were restored to Ferdinand. The use which he made of the lucid interval thus vouchsafed to him, was to dismiss his ministers, to appoint the queen regent during his illness, and to undo what he had lately done regarding the succession, thus restoring to his daughter her right to the throne. The decree to this effect was issued on the last day of the year. The former ordinance, he declared, had been extorted from him, not only when he was in the agonies of expected death, but under false misrepresentations that all Spain demanded it, and that the inviolability of the monarchy required it; whereas it had only been desired by an ambitious and unscrupulous faction, and was opposed to the fundamental laws of the kingdom. A more liberal ministry was formed, and some liberal measures were adopted; high expectations were raised that milder times were at hand, and the funds in Madrid rose ten per cent. Early in 1833, Ferdinand was able to resume the reins of government. On the 20th of June he assembled the Cortes to swear allegiance to his daughter, and do homage to her as their future sovereign. This solemnity was performed with great pomp in the church of the royal monastery of St Jerome. Don Carlos refused to take the oath; but previously to this he had taken up his residence in Portugal, where his nephew was playing the same desperate game which he himself was about to undertake. Ferdinand survived the ceremony of the *jura* only a few months. He expired on the 29th of September 1833, leaving a will, in which he appointed his daughter Isabella heir to the crown, and her mother regent during her minority.

No sooner was Isabella II. proclaimed queen, than Don Carlos announced his claim to the throne, and the flames of civil war burst out in the northern provinces, where his partisans, assembled in great numbers, stood ready armed for the contest. Of the bloody and protracted struggle for the throne which ensued, we can afford room for few details; indeed, an account of the numerous battles, skirmishes, sieges, and other warlike operations, would prove a very uninteresting and monotonous portion of the modern history of Spain. Isabella was acknowledged without opposition throughout all the provinces of Spain, and by the leading powers of Europe. The question of the Spanish succession, apart altogether from the bloody war to which it gave rise, has been keenly agitated in this and many other countries. It may be briefly stated as follows. Carlos's right rests upon the Salic law, which had never the force of law in Spain. The Salic law was not the ancient rule of succession; it was first introduced by the Bourbon Philip V., the great-grandfather of Don Carlos. Females could always succeed in Castille, Leon, and Portugal. It was by marriage with the heiress of Navarre that a king of France obtained a claim to that kingdom; and although females were excluded in Aragon, yet it was through a princess that its inheritance passed to the counts of Catalonia. It was by the right of female succession that the house of Austria reigned in Spain; it was by the same right that the Bourbons themselves occupied the throne. It formed a part of the Partidas, or system of constitutional law, which Philip swore to observe on his succession to the throne. The Salic law, on which Carlos grounds his claim, could only be established in two ways; by the old forms of the constitution, or by the despotic will of the sovereign. If the advocates of Don Carlos take their stand on the former ground, the answer is, that the forms as well as the substance of the constitution were violated when Philip V. established his law of succession; and that, conscious of its invalidity, he did not register it in the form usual with similar acts; while again, if we pass over the Cortes of 1789 as secret and irregular, we have the Cortes of Cadiz in 1812, which abolished the decree of Philip, and restored the ancient law of the Partidas. But Ferdinand having annulled the proceedings of this body, its re-establishment of the right of female succession must fall to the ground with its other decrees. There is however Ferdinand's own decree, constituting his daughter his successor, which was just as regularly sanctioned by the Cortes as Philip's law of succession. If, on the other hand, the sovereign is to be regarded as despotic in Spain, the question is at an end; for even Carlos must acknowledge that Ferdinand had a right to regulate the succession according to his own royal pleasure. This view seemed to have been taken by the king's confessor, and his minister Calomarde, when, during his dangerous illness at La Granja in 1832, they induced him to sign a new will, settling the crown on Don Carlos. Ferdinand's recovery disconcerted their plan; but their effort plainly shows that the partisans of Don Carlos at that time felt that the Salic law was a very weak support to their favourite's claims. The transaction by which Ferdinand (supposed to be on his death-bed) transferred the crown to his brother, is admitted by the Carlists to have been a perfectly legal proceeding. Can the subsequent transaction, by which, under exactly similar circumstances, the king appointed his daughter his successor, be considered otherwise than as an equally legal proceeding? If the constitution be referred to, the question is decided against Don Carlos; the will of the sovereign is against his claim; and, what is of yet more consequence, as the event has shown, the will of the majority of the nation is against him.

It was in the northern provinces, in Navarre, Guipuscoa, Biscay, and Alava, that the strength of Don Carlos lay. Here he was immediately proclaimed in several towns by the title of Charles V., and bands of Carlist guerillas assembled to maintain his right to the throne. He himself still hovered a fugitive on the frontiers of Portugal, his movements being closely watched by a royal force under General Rodil. Another strong division of the queen's army, under General Sarsfield, marched against the disaffected provinces. The Carlists retired before him; Bilboa and other towns were occupied and garrisoned; the constitutional party was restored in several places where it had lost ground; and the insurrection seemed at first to have been happily put down without much loss. But early in 1834 the affairs of the Carlists assumed altogether a new aspect. Hitherto their operations were carried on in an unconnected manner; this system was now exchanged for one of steady unity of design. Indeed so numerous were the adherents of Don Carlos in the north, that there was only required a firm hand to seize the reins, control local jealousies, and direct aright the energies of the provinces. Such a man was Thomas Zumalacarreguy, who now assumed the chief command of the Carlists. He was admirably skilled in the desultory warfare of these provinces, and well acquainted with the country and with the character of the inhabitants. By his activity and enterprise he repeatedly inflicted severe blows upon the forces of the queen, or the Christinos, as they were generally called. His method of fighting was to surprise the enemy in an unprotected position, and cut off as many of them as he could before they recovered from their panic. His troops would then suddenly separate and fly, but only to unite again at a predetermined point some miles in the rear. By this mode of warfare he caused great loss to the Christinos, while his own small band suffered little. The Christino army under General Rodil, who had now obtained the chief command, might amount to 20,000 men, and was thus sufficiently strong at least to have confined Zumalacarreguy to the mountains; but it was greatly reduced by several thousand troops having been distributed among a number of petty fortresses, most of which, one after the other, fell a prey to the Carlist chieftain. It was further weakened by being divided into different corps and scattered over the country. Rodil found it necessary to resign the command, which now devolved upon Mina, from whom much was expected. Nor did he disappoint the hopes which were formed of him. Just before his appointment, Generals O'Doyle and Asina had severally been defeated with great loss by Zumalacarreguy, which occasioned much alarm at Madrid, and loud outcries against the ministry. But the old warrior, though broken by sickness and infirmities, restored confidence by making head against the hitherto victorious Carlists, and bringing victory to the standards of the queen.

In the mean while, Don Carlos, after paying a short visit to England, made his appearance in Spain; and his presence among his partisans greatly strengthened his cause in the northern provinces. France and Britain had acknowledged Queen Isabella II. These two powers, along with Portugal, entered into a treaty with Spain, the conditions of which quadruple alliance were, that France should watch the frontiers, so that the insurgents might receive no aid from that country; that Britain should supply such arms and munitions of war as the Spanish government should stand in need of, whilst at the same time she should guard the northern ports of Spain, so as to prevent the insurgents from receiving any assistance in men, money, or ammunition, and also assist the queen with a naval force; and that Portugal should co-operate by every means in her power: but that country was at the time in too embarrassed a situation to render any efficient assistance. As soon as the arrival of Don Carlos in Navarre was known, the four powers who had been parties to the treaty renewed its stipulations, in respect that its object had not yet been attained. This imparted confidence and vigour to the cabinet of Madrid, of which it stood greatly in need. A variety of measures occupied the attention of government during the year 1834, not the least important of which was the plan of a new charter or constitution. It is quite unnecessary to enter into any details of what the Cortes proposed should be done, as every thing was overturned and put upon a new footing by a revolution which occurred two years afterwards. The financial state of Spain, particularly the large debt which the government owed to foreign nations, formed a subject of protracted discussion. Doubts were raised as to whether a part of it was legitimately owing; but the debates in the Cortes terminated in the whole being recognised as justly due. This contributed to restore the credit of Spain in foreign money-markets, where it had been greatly shaken, and enabled the government to contract for a new loan. Another measure of importance which engaged the attention of the Cortes, was the passing of a bill of exclusion from the throne against Carlos and his descendants. During the year the ministry had undergone a complete change, chiefly through the instrumentality of a popular leader of the name of Llauder. Zea was superseded in the office of prime minister by Martinez de la Rosa, supposed to be a person of more liberal predilections.

The military operations of 1835 were prosecuted with great vigour on the part of the Carlists. Several important towns and fortresses fell into their hands, and siege was laid to Bilboa, the capital of Biscay. After sustaining a furious bombardment for several days, the place was relieved, principally through the instrumentality of some British gunners under Lord John Hay, commander of a ship of war then on the coast of Biscay. It was during the attack on Bilboa that Zumalacarreguy received the wound of which he died on the 23d of June. The death of this chief threw a gloom on the affairs of Don Carlos: it was the severest loss which his cause had sustained, and he never properly repaired it. Among the Christinos this event diffused a joy and hope which they made no efforts to conceal. Worn out by long service, by age, and by disease, the veteran Mina resigned the command, which ultimately devolved upon General Cordova, under whom was the celebrated Espartero. The Spanish government having been permitted to levy a body of mercenaries in Great Britain, several thousand recruits were raised in this country, and were led to the theatre of war in Spain under the command of General Evans. The British legion soon took an active part in the war, and distinguished itself upon various occasions. The Carlist army, although it abandoned the siege of Bilboa, still continued in the neighbourhood, prepared to take advantage of circumstances. An opportunity soon occurred for attacking the Christinos at the village of Arrigoriaga, which they made an attempt to pass. The royalists were driven back with considerable loss, and this check for the time interrupted the movements of Cordova's army. On the other hand, the Christinos laid claim to more than one victory gained over their enemies; but these doubtful and unproductive skirmishes, which in the flush and enthusiasm of triumph were magnified into decisive battles, are too insignificant to require a detail in this place. At the close of 1835, matters stood much as they did at the commencement of the year. But the war was now carried on with more humanity than formerly. A strong remonstrance on the part of the British government, against the barbarous practice of putting prisoners to death, had the desired effect, at least for a time, of staying the effusion of blood in this inhuman manner.

Those parts of Spain exempt from the horrors of war, were for the most part subjected to the scourge of political anarchy. The new government of the queen-regent had been founded on an abandonment of the old system of unmitigated despotism. Her daughter's throne was to be identified with more liberal institutions, and was thus to be protected by all political reformers, all who were inimical to absolutism. But the extent to which the old system was to be abandoned, and the form in which a popular government was to be established, were questions regarding which every possible diversity of opinion prevailed. The unquiet elements thus at work showed themselves first in a military revolt, and then in the revolt of several provinces, in which the democratic party sought to usurp the powers of government. For a time they set the lawful authorities at defiance, for the government of Madrid was helpless. Even here disaffection had spread to a most alarming extent, the urban militia having openly revolted. In vain were royal decrees issued, and strong measures put in force to repress the disturbances; an open war between the government and numerous sections of the liberals seemed on the eve of breaking out. Fortunately this was averted by a change of the ministry, which was loudly demanded by the factious opposition. The life and soul of the new ministry was Mendizabel, a man of great vigour, and very popular among the people, on account of his liberal principles. He condemned the repressive measures which had been acted upon, adopted a more lenient system of dealing with the malcontents, and proposed various alterations in the constitution, the mere mention of which sufficed to restore the country to comparative tranquillity. But all the deliberations of the ministry and the Cortes were rendered abortive by the military revolution which broke out at Malaga on the 25th of July 1836. The object of the ultra liberals had uniformly been the restoration of the constitution of 1812. Without this no change of ministers could satisfy them, and no vigilance on the part of government could prevent them from covertly prosecuting their designs. It was with the national guard that the revolt originated. In Malaga the governor was assassinated, and a junta was appointed to proclaim the constitution. Intelligence of these events spread throughout the country with the greatest rapidity. Cadiz and Saragossa took up the signal nearly at the same moment; and they were instantly followed by Seville, Cordova, Granada, and Valencia. At length the capital itself joined the insurgent cities; and on the 13th of August the queen, now deserted and helpless, was compelled to issue a decree, promising the restoration of the constitution of 1812. But all men who were reasonable and honest in their politics felt and admitted that some alterations in that code were quite indispensable. The Cortes accordingly appointed a committee to consider and propose such alterations as were necessary and advisable; and this they accomplished in a highly satisfactory manner. The changes recommended and finally adopted by the Cortes were, 1st, that the part of the constitution which contained mere regulations and forms, and regarded organic bodies and laws, should be entirely suppressed: 2dly, that instead of the Cortes continuing to form, as they did under the constitution of 1812, only one body, they should now consist of two bodies, differing from each other in the personal qualification of their members, &c. but neither to be hereditary nor privileged: 3dly, that the crown should have an absolute veto in the enactment of laws, and should likewise have the power of convoking, proroguing, and dissolving the Cortes; but in the latter case to be under the obligation of assembling others within a given time: 4thly, that the election of members of the Cortes should be direct, and not indirect, as established by the constitution of 1812.

While Spain was thus undergoing the most momentous political changes, the very existence of the queen's government was threatened by the Carlists, who were making alarming progress in the very centre of the kingdom. During the early part of the year the Christinos attacked the position of the Carlists at Arlavan, but with so little success that they were compelled to make a retrograde movement. However, early in May, the British legion, under General Evans, gallantly carried the Carlist lines before St Sebastian; but unfortunately this victory, like many others gained, was productive of no important result, chiefly through the sloth and inactivity of the Spanish generals. The circumstance which created the great alarm to which allusion has been made, was the march of a large body of Carlists under Gomez through the very heart of Spain. This chief penetrated from province to province, to the centre of Andalusia, laying the country under heavy contribution, and carrying off loads of booty from every place which he visited. The audacity of this enterprise seems for a time to have paralyzed the royalists. Consternation spread over Spain from Madrid to Gibraltar. Gomez attacked and carried several towns, and some bodies of troops who attempted to arrest his progress were totally destroyed. No less than three distinguished Spanish generals, each with a large army, were despatched to cut him off; but all their efforts to entrap him and his daring band proved fruitless. He was repeatedly surrounded, and apparently on the eve of being taken, but always succeeded in effecting his escape. At length, however, he was hemmed in to the sea-coast at San Roque, and his destruction seemed inevitable; but, by a daring and masterly movement, he broke through the line which encompassed him, and secured his retreat to the strongholds of the north.

Towards the close of 1836, the town of Bilboa was again invested by the Carlists, to whom it was an object of great importance, as being a city of sufficient consideration to give dignity to the court of Carlos, and an appearance of permanence to his establishment. It was, besides, the capital of Biscay, and inseparably connected, in the eyes of the Basques, with their *fueros* and local parliament. The siege was carried on with an ardour corresponding with the importance attached to the place. The defence was equally spirited and heroic. During the sixty days which the investment lasted, the fortitude of the besieged was put to the severest test, not only by the long-continued fire of the Carlists, by their repeated attacks, and by their mining operations, but by want of proper food and by sickness. At length General Espartero succeeded in compelling the Carlists to retire with the loss of all their guns and *matériel* for the siege, and Bilboa was relieved. The intelligence was received at Madrid with unbounded enthusiasm, and honours and rewards were heaped upon the defenders, and those who had so opportunely relieved them. The Christinos, however, as usual, neglected to follow up the success, allowing the Carlists to remain unmolested in the neighbourhood. Near St Sebastian they mustered very strong during the early part of 1837, and here they were attacked by the Anglo-Christinos under General Evans, and driven back with some loss; but receiving a great accession of strength, the Carlists in their turn compelled the royalists to retreat with at least equal loss. The affair of Hernani would have been much more disastrous, but for the steady bravery of a small body of British marines, who checked the advance of the Carlists, and retired to St Sebastian in good order. In a subsequent attack on Irun and Fuentarabia, General Evans was completely successful; but it seems perfectly clear that this officer was never cordially supported by the Spanish commanders. The defeat before Hernani would never have taken place had Espartero and Sarsfield supported him according to the concerted plan. The time for which the British legion volunteered its services expired in the month of May, and shortly afterwards it disbanded, nearly the whole returning to England in the most destitute condition. Meanwhile Don Carlos had followed the example of Gomez, by marching an army through the central parts of the kingdom. Our limits will not permit us to follow him in this daring but useless expedition. One body of Carlists advanced within a few leagues of Madrid, and all was consternation in the capital. But the Christino generals concentrating their forces, compelled the main body of the Carlist army to retire from the provinces into which it had made so fierce an irruption. Disunion also began to show itself in the camp of Don Carlos, so that, disappointed and disheartened, he retreated to his old fastness beyond the Ebro, accompanied however by a large convoy of booty. Besides these military operations, prosecuted on a large scale, there was a system of desultory warfare maintained all over the country, more destructive in its effects upon the inhabitants than the regular operations of an army. Brigandage, never viewed with much horror in Spain, had now become as common as a lawful trade. Remorseless cruelty characterized the proceedings of all parties; and civil life, except in the large towns, seemed for the time suspended.

The civil and parliamentary history of Spain for 1837 presents little that is of any importance. The new constitution formed a fruitful theme of discussion in the Cortes. After undergoing the alterations already mentioned, and some others of less moment, it was solemnly ratified by the queen-regent in the Cortes, and proclaimed to the nation. It is worthy of being noticed, that an attempt to introduce toleration in religious matters, by an amendment to the article which establishes the Catholic faith, met with the strongest opposition. This striking fact shows how deeply rooted the old Spanish bigotry remains in the national mind. During the year, bills were passed for the suppression of religious houses, and the abolition of the payment of tithes, the maintenance of the clergy being left to the government. Several judicious ecclesiastical reforms were projected; and among other important measures passed by the Cortes, was the abolition of the local parliaments in the Basque provinces. Ministerial changes repeatedly took place during the year, but into these we shall not enter.

The military operations of the Carlists in 1838 were less successful and less enterprising than they had been during the two previous years. Cabrera, indeed, a general who had frequently signalized his talents for war, had firmly established himself in Aragon and Valencia, and the bands of partisans allowed no respite to the distracted provinces; but we have to record none of those daring and brilliant flying expeditions which more than once traversed Spain in all directions with such celerity and success as to command the attention of Europe. Something of this kind was indeed attempted by Basilio Garcia, and by Tallada, but both these generals were signally defeated. The cause of Don Carlos was now visibly declining: the best and bravest of the chiefs who had served him had successively incurred his displeasure, and were either in disgrace, exile, or confinement; above all, the country was beginning to be favourably disposed to the queen. Her troops however were very unsuccessful in the field. General Orad was defeated at Morella, and General Alaix also suffered a repulse. But the principal battle fought between the Carlists and Christinos was that of Maella, where General Cabrera completely routed the queen's troops under Pardinas, but sullied his victory by butchering nearly two hundred prisoners in cold blood. The war throughout had been disgraced by similar atrocities, notwithstanding the efforts of Britain to put a stop to them. Both parties appear to have been equally guilty of this inhuman practice. The operations of Espartero were feeble and uncertain. He did little but march a large army from place to place, without striking a decisive blow. As usual, almost every part of Spain continued to be ravaged by guerilla bands, who swarmed over the provinces with no other objects in view but plunder and bloodshed. During the year, the Cortes had twice met; their deliberations chiefly referred to the state of the finances and the negociation of a loan, which was not effected. The ministry, always feeble, had now become more feeble than ever, notwithstanding that changes were continually taking place. The queen-regent found it impossible to form a strong government in the present political state of the country. Its helplessness was such that the generals commanding in the different provinces found it necessary to act independently of its arrangements, and to appropriate the revenues of each province to the payment of the military expenses incurred in it, instead of allowing the monies to pass into the treasury. Thus General Van Halen, who had organized a fine army of 40,000 men, called the army of the centre, after declaring the kingdoms of Aragon, Valencia, and Murcia, in a state of siege for the rest of the war, and that in future the civil were to consider themselves in subordination to the military authorities, proclaimed, that the entire revenues of those provinces should be paid into the military chest, and exclusively appropriated to the expenses of the war. This was probably the very wisest measure that could have been adopted for bringing the war to a speedy termination. Want of pay had repeatedly paralyzed the operations of the Christino armies; it had dispersed the British legion; and at this very moment it was exciting discontent, if not revolt, in the camp of Don Carlos. To place the pay of the queen's troops upon a sure footing, was therefore the first step to secure ultimate triumph in the field.

During 1839, the cause of Don Carlos rapidly declined, notwithstanding the desperate efforts made by Generals Cabrera and Maroto to maintain it. Espartero, the commander-in-chief of the queen's troops, after some hard fighting, cut off the Carlists completely from the plains of Alava, while Diego Leon likewise expelled them from the rich country between the mountains and the Ebro. Many towns and fortresses of importance, one after another, submitted to the triumphant Christinos, so that almost the only parts of Biscay which now owned the authority of Carlos were rugged mountainous tracts of country, whither no regular army could follow the fugitives. An armistice was at length concluded between Maroto and Espartero, which was followed by twenty-one Carlist battalions laying down their arms. Don Carlos himself, reduced to the last extremity, fled for refuge into France, where he formally renounced his pretensions to the throne of Spain, under certain conditions alike reasonable and necessary. The question relative to the fueros of the Basques and Navarre, which, it will be recollected, had been abolished, caused much uneasiness. It seemed perfectly evident that these important provinces would not be satisfied, or completely surrender themselves to the queen's authority, unless their local privileges were restored. After some debating in the Cortes this measure was agreed to, government stipulating that it would so modify the fueros as to reconcile the interests of these provinces with those of the nation, and with the constitution of the monarchy. The only Carlist chief who gave any uneasiness to the government was Cabrera, who, little affected by the pacification of the northern provinces, still maintained his footing in Valencia, determined to support the cause of Carlos while an army remained to back him. Towards the close of the year, however, sickness paralyzed his exertions; nor is it supposed that he will be able to effect much when the season again arrives for an army taking the field. It is to be hoped that this protracted, bloody, and disgraceful war is now virtually at an end. It has left Spain overwhelmed with a debt which at present she has no prospect of being able to pay for many years to come. National property, chiefly that of the church, was sold to the amount of L.10,000,000, to meet the exigencies of the time, but even this large sum fell far short of what was required. The resources of the country are no doubt great, but a long period of peace, and a wise administration of public affairs, will be necessary before these are developed to their full extent. Spain has scarcely been free from internal war since this century commenced. The injury thus inflicted on agriculture, commerce, trade, and manufactures, is not to be estimated, while its effect on the morals of the people has been most pernicious, transforming the peaceful husbandman into a robber, and the aspiring student into a leader of banditti. That Spain has struggled through this sanguinary period of her history without being involved in total ruin, proves that the natural resources of the country are immense, and only require proper management to raise her above her former rank in the scale of nations.

STATISTICS.

The position and boundaries of Spain have already been described. Its extent north and south is from Tarifa Point, in the Straits, in 36° north latitude, to Cape Ortegal in Galicia, 43° 46′, making 7° 46′ of latitude, or about 540 English miles. From east to west the extreme points are Cape Creus, in Catalonia, 3° 17′ of east longitude, and Cape La Roca, 9° 17′ of west longitude, the distance in this direction being 560 miles. The Peninsula thus forms almost a square, allowance being made for the irregularity of its outline; and the entire extent of Portugal being excluded, it is reckoned to contain about 176,000 square miles English.
